THIS little handbook is written for first-year nurses. The authoress, Miss McIsaac, is clearly well acquainted with the subject. Speaking from the basis of a fairly wide acquaintance with books upon nursing, we can confidently say we know of none which occupy quite the same place as this little volume. The essential point is its practical nature, and, so far as we have tested its pages, the information given is sound and accurate. The ground covered by the writer embraces a vast variety of surgical and medical technique, some of which, such as gastric lavage, we should have imagined somewhat beyond the field of action of a nurse in her first year. The price of this excellent little book is 3s. net.

MEDICAL NEWS IN BRIEF

Claim by a Medical Man.

Dr. John Wilson, Cheltenham, at Gloucester Assizes, on February 18th, sued Mr. Hugh Baird for £732 for professional services rendered to the defendant and his wife between July 13th and November 20th, 1906.

Defendant paid £380 into court.

Paintiff's counsel said the circumstances were very exceptional, rendering special medical charges necessary. Mr. Baird suffered from chronic alcoholism, and was almost a dipsomaniac. Sometimes plaintiff was in attendance all night, and he had charged as much as £20, £30, and £50 a night, as defendant on these occasions required the whole of his attention and was very troublesome.

Mr. Baird alarmed the house and terrified the servants. On one occasion defendant was in the grounds in pyjamas, and was going to attack plaintiff, when his wife put her thumbs in his mouth, as a bit, and controlled him.

Plaintiff's charges for the period mentioned included £232 for day attendances, sometimes going three times a day, at one guinea per hour, and £500 for 14 night attendances.

Plaintiff said he was specially requested to get defendant fit for a garden party in his grounds, and did so, but next day he was as bad as ever. Defendant secreted spirits in all sorts of places. Once he threatened to throw himself out of the window, and plaintiff told him if he did his insurance money would all go, and what would be the use of that? That brought Mr. Baird to his senses. Plaintiff considered the charges were fair under the exceptional circumstances.

Medical evidence was called on both sides, and the jury eventually awarded plaintiff two guineas extra for each of the 14 nights, besides the £380 paid into court.

£30,000 for a Special Hospital for Mental Diseases.

An offer of £30,000 towards the cost of a special hospital for mental diseases has been made to the London County Council by Dr. Henry Maudsley. The offer was conveyed to the Council in a letter to the Chairman, which was read at last week's meeting. The following are the important features of the proposal, as outlined in Dr. Maudsley's letter:—

"As a physician who has been engaged in the study and treatment of mental diseases for more than half a century, I have been deeply impressed with the necessity of a hospital, the main object of which would be (1) the early treatment of cases of acute mental disorder, with the view, so far as possible, to prevent the necessity of sending them to the county asylums; (2) to promote exact scientific research into the causes and pathology of insanity, with the hope that much may yet be done for its prevention and successful treatment; and (3) to serve as an educational institution in which medical students might obtain good clinical instruction. The outline of the scheme is that the hospital should be for 100 patients suffering from recent and mostly acute insanity."

The Vice-Chairman of the Council (Mr. Stuart Sankey) proposed a hearty vote of thanks to Dr. Maudsley for his generous offer. Captain Hemphill (Deputy Chairman) seconded, and the motion was adopted, the letter being referred to the Asylums Committee for consideration and report.

Viewing the Body.

The text of the Bill to dispense with the compulsory viewing of bodies on the holding of coroners' inquests was published last week. The proposed measure is presented by Mr. Higham, supported by Mr. Luke White, Mr. Arthur Henderson, Mr. Summerbell, Mr. Toulmin, and Mr. Cameron. It is proposed that it shall not be necessary for either the coroner or jury at any inquest to view the body, unless the coroner, or at the first sitting of the inquest a majority of the jury, shall deem a view necessary. The Bill also seeks to amend the form of the oath of a coroner's jury by the omission of the words "of whose body you shall have the view."

Irish Medical Schools' and Graduates' Association.

The thirty-first annual general meeting of the Association will be held at the Hotel Great Central, Marylebone Road, London, on Tuesday, March 17th, 1908, at 6.30 p.m., when it is particularly requested members will make an effort to attend. On the same evening the members of the Association will dine together at the Hotel Great Central, at 7.15 for 7.30 p.m., the President, Sir Charles Cuffe, K.C.B., in the chair. The Rt. Hon. Sir Edward H. Carson, P.C., and Professor Windle, President Queen's College, Cork, will be the guests of the Association.

Royal College of Surgeons of England.

At an ordinary meeting of the Council, held at the Royal College of Surgeons of England, the following were admitted members of the College:—

A. C. Anderson, C. E. Anderson, A. G. Atkinson, T. R. H. Blake, H. Blakeway, S. L. Brimblecombe, J. P. Buckley, W. A. Burr, H. J. B. Cane, E. P. Carmody, A. J. W. Cunningham, S. T. Davies, B. Day, A. F. W. Denning, A. Dixon, J. McD. Eckstein, J. Everidge, A. L. Foster, H. Gall, E. W. Gandy, E. G. Gauntlett, W. Gilliatt, H. D. Gillies, G. R. Girdlestone, A. E. Gow, A. Hamilton, C. T. Hawkins, C. A. Holburn, N. W. Jenkin, G. Ley, E. L. M. Lobb, D. Loughlin, A. T. McCaw, D. Macrae, C. H. Marshall, J. B. Martin, T. M. Miller, R. J. G. Parnell, E. M. Parsons-Smith, H. Pinto-Leite, H. J. D'A. G. Price, R. B. Price, J. F. E. Prideaux, E. J. J. Quirk, P. C. Raiment, R. W. Rix, H. T. Rossiter, Mulk Raj Sawhney, F. C. Searle, L. W. Sharp, F. H. Stephens, H. Stott, G. F. Syms, W. R. Taylor, E. W. Toulmin, N. H. Vakeel, C. F. Walker, A. G. Wells, E. G. Wheat, J. N. Wheeler, E. B. C. White, W. C. Wigan, C. O. O. Williams, R. R. Williams, J. S. Williamson, W. L. R. Wood.

Royal College of Surgeons in Ireland.

Fellowship Examination.—The following candidates, having passed the necessary examination, have been admitted Fellows of the College:—B. P. Banaji, L.M. and S., Bombay Univ.; P. T. Carpenter, M.R.C.S.Eng., etc.; M. D. Healy, L.R.C.S.I., etc.; H. L'Estrange, L.R.C.S.Edin., etc.; T S. Reddy, L.R.C.S.Edin., etc.

The following passed the Primary part of the examination:—H. G. P. Armitage, Student R.C.P. and S.I.; K. K. Chatterji, L.M. and S., Calcutta University; W. Doolin, Student Roy. Univ. Irel.; A. Foley, Student R.C.P. and S.I.; E. W. O'G. Kirwan, Student Roy. Univ. Irel.; A. M. Lanphier, Student R.C.P. and S.I.; J. S. Pegum, Student R.C.P. and S.I.; R. H. Weir, Student R.C.P. and S.I.; R. White, Student R.C.P. and S.I.

Society of Apothecaries of London.

The following candidates passed, February, 1908, in:—

Surgery.—H. M. Jones (Section II.), F. B. O'Dowd (Section II.).

Medicine.—C. F. Curtis (Sections I. and II.), M Fisher (Sections I. and II.), O. C. H. L. Moll (Section I.), E. H. Paterson (Sections I. and II.), L. G. Powell (Sections I. and II.), W. W. Stacey (Sections I. and II.), N. C. Wallis (Section II.), H. F. Wight (Section I.).

Forensic Medicine.—C. F. Curtis, H. W. E Danaher, F. S. Hawks, L. G. Powell, H. C. Simpson, S. Speelman.

Midwifery.—L. G. Powell, H. C. Simpson, W. W. Stacey, S. H. Sugden.

The Diploma of the Society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—C. F. Curtis, F. B. O'Dowd, E. H. Paterson, and W. W. Stacey.

There are at present 23 patients suffering from cerebro-spinal meningitis in hospital at Belfast. During the week six fresh cases and three deaths occurred in the town.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Non-Filarial Chyluria.—Dr. Hertz presents a study of a case of chyluria occurring in England (*Guy's Hosp. Reports*, Vol. LXI., p. 857, and a short review of the previously recorded cases. The patient was a sailor, æt. 66, who had last visited the Tropics in 1886, and who was admitted to hospital in October, 1907, with pain in the loins, loss of flesh, and marked chyluria. A careful search for filariæ in both the blood and urine, at different times of the day, yielded no result, and as there was no eosinophilia, it was concluded that the case was due to some other cause. The fat in the urine was in extremely minute particles, resembling the molecular basis of chyle; a few leucocytes, some fibrin and albumin were also found, but no casts nor dextrose. From time to time the chyluria disappeared, as in other recorded cases, without apparent cause. The amount of fat varied directly with the fat taken in the food, and was found to increase steadily every hour up to the fifth after an ordinary breakfast or dinner. Exercise, especially of the lower extremities, definitely increased the amount of fat and albumin present, while posture independent of exercise did not appear to have any effect. A cystoscopic examination undertaken with the object of ascertaining whether the chyle entered the urine above or within the bladder did not yield any definite result. The patient died from an attack of acute bronchitis, and at the post-mortem examination an obstruction was found in the thoracic duct about 7 c.m. above the receptaculum chyli. Injection of the abdominal lymphatics failed to show any enlargement of those from the kidneys and ureters, but those on the right side of the bladder were very much enlarged and anastomosed freely with the intestinal lymphatics. From this fact the author concludes that a leakage most probably took place from these enlarged lymph channels direct into the bladder. It was not possible to drive mercury through them into the bladder cavity, but this, he thinks, may be explained by the fact that the chyluria had ceased for some days before death.
M.

Aspiration of a Pneumothorax under the X-Rays.—Fawcett reports a case of pneumothorax successfully treated by aspiration (*Guy's Hosp. Reports*, Vol. LXI., p. 49). The patient, a man, æt. 22, was admitted with the typical symptoms and signs of a right-sided pneumothorax. The cause was unknown, the only recent illness being an attack of pneumonia two years previously. There was no cough, expectoration, or hæmoptysis, and the tuberculo-opsonic index was normal. There was slight fever at first, but this soon subsided, without, however, any expansion of the lung taking place. Accordingly, after 19 days, it was decided to aspirate, and a trocar and cannula were introduced into the sixth intercostal space. The tubing of the cannula was then connected with a sterilised Winchester bottle, from which the air had been partly exhausted, and on turning the tap air was found to pass from the pleural cavity into the flask, while at the same time the lung was found to expand. The cannula was withdrawn, and a dressing placed over the punctured wound. The patient was kept on the couch for some time, and the lung was found to remain expanded and to move with respiration. The patient finally left hospital twelve days later, quite well.
M.

The Blood and Urine of New-born Infants.—Biffi and Galli have investigated the blood and urine of newborn children, and report as follows (*Journ. de Physiol. et de Pathol. Génér.*, IX., 5, p. 723):—(1) The red blood corpuscles continue to increase after birth, and reach a maximum on the second day. They remain at a high level for a week, and then gradually begin to diminish in number. (2) The volume of the red cells, estimated by a sedimentation method, varies directly with their number, and is greatest also on the second day. (3) The number of white cells falls after birth, and reaches a minimum about the seventh day of 12,000 cells per c.m. This number then remains constant for about a month. (4) During the first week the neutrophile cells preponderate, but after this the lymphocytes begin to increase. Nucleated red cells disappear after the sixth day. (5) The coagulation time is lengthened, the first formation of fibrin being noted nine minutes after the blood is drawn, and full coagulation only in about 20 minutes. (6) The urine during the first few weeks contains a colouring matter, similar to what is found in the blood plasma, and which appears to be bilirubin.
M.

New Test for Lactic Acid.—Thomas employs as a test for lactic acid the brown colour which is produced on treating this acid with a solution of chromic acid (*Zeitschrift f. Physiol. Chem.*, Bd. 50, S. 540). The colour is not given by acetic acid, butyric acid, hydrochloric acid, or acetone. The reaction is obtained by treating 6 c.c.m. of gastric contents with 3 or 4 drops of a 33 per cent. solution of chromic acid in a water bath for ten minutes. A bright yellow colour is first produced, which changes gradually to a reddish brown. The test is so fine that it detects .01 per cent. of lactic acid. The addition of a few drops of peroxide of hydrogen causes the colour to appear in the cold after a few minutes.
M.

Review of Five Years' Experience with HCl Treatment of Gout.—Falkenstein (*Berlin Klin. Woch.*, Dec., 1907) reviews the work of Pfeiffer, van Loghem and Lilbergleit, Brugsch and Schittenhelm on the effect of large doses of HCl in gout. He agrees with their results, but does not believe that gout is due to a faulty nuclein metabolism. He lays most stress on the fact that in the stomachs of gouty persons, according to most observers, there has been a lack of HCl. In the last five years he has treated 390 cases of gout with HCl, including himself. He himself is taking about 60 gtts. of concentrated HCl per diem, well diluted. Most of his cases, whether early or very marked, have had relief from attacks, or the severity of the attacks has been lessened. Colchicin, aspirin, and many other remedies recommended for gout have had a certain amount of influence on the course of the acute attack, and have alleviated pain, but have not influenced the course of the disease, which the author claims may be arrested by the continued use of HCl.
D.

The Heart Reflex and the Mechanism of Angina Pectoris.—(*Adams' Med. Record*, Dec., 1907.) The heart reflex is a contraction of the myocardium of varying duration, brought on by reflex irritation. Irritation of the skin in the præcordial region brings out this reflex, but it is also elicited by irritation of more remote regions, *e.g.*, of the nasal, œsophageal, gastric and rectal mucosæ, by percussion of the muscles, vertebral concussion and by psychic irritations. That it is a true reflex is shown by the fact that it does not appear when the mucous membrane becomes anæsthetic by cocain. This reflex is best observed by the X-ray. It is more manifest in the left than in the right ventricle. In some individuals it may be scarcely perceptible, while in others the heart's outlines may recede more than 2 c.m. In persons with dilated hearts the reflex is especially evident and much more prolonged. As a rule the duration is over two minutes. When the reflex is in evidence, the heart is practically inhibited. Inasmuch as the factors precipitating a paroxysm of angina are equally operative in inducing the heart reflex, viz., emotion, muscular exertion, etc., the writer is led to the ingenious conclusion of the connection between the two conditions. The coronary arteries in his theory are passive agents. The heart is inhibited and contracted; hence a claudication ensues which explains the symptoms. D.

Migraine and Epilepsy.—Gordan (*Therapeut. Gaz. Detroit*, Dec., 1907) reports ten cases to illustrate the principle that migraine due to morbid metabolism has an undoubted relationship to a faulty thyroid function. Migraine patients with migraine are usually free from the affliction during pregnancy, during which period there is functional hyperactivity of the thyroid. Of course, not all cases are directly ascribable to this source, but the therapeutic test by thyroid feeding is at the same time diagnostic as regards pathogenesis That there is a relation of the seizures of essential epilepsy to a faulty chemistry of the organism is now generally admitted. The six patients who were studied with special care for a long time all showed signs of hypothyroidisation. When the thyroid treatment was instituted a remarkable change took place, first, in the general condition, then the epileptic seizures became rare. There is a certain class of epileptics whose seizures are in direct relationship with a disturbed function of the ductless glands, particularly the thyroids. In such cases the failure of the usual treatment lies in the want of thyroid feeding. D.

Intestinal Arteriosclerosis.—Cheinisse (*Semaine Med. Paris*, Dec., 1907) reviews the scanty literature on arteriosclerotic changes in the intestinal vessels and the symptoms which they elicit. Abdominal pain, in persons past 40, occurring in paroxysms, generally after physical exertion or emotional stress, should suggest intestinal arteriosclerosis, he states, especially if the pain comes on when reclining. The mechanism of the disturbance is similar to that of intermittent limping—the ischæmia of the intestinal vessels causing painful cramp with transient paralysis of some segment of the intestine and consecutive meteorism. The trouble has been called "intermittent ischæmic dysperistalsis" and "intermittent arteriosclerotic intestinal dysphagia." Dubious cases may be differentiated by giving tincture of strophanthus, from 5 to 8 drops three times a day. Narcotics and other measures to soothe the pain are generally useless, but drugs that control angina pectoris may prove effectual, especially strophanthus and theobromin. Jaquet has reported excellent results from the use of potassium iodide or potassium nitrate combined with sodium nitrate, the combination recommended by Sir Lauder Brunton for chronic arterial hypertension. D.

Ætiology of Infantile Eczema.—Hall (*Brit. Journ. of Dermat.*, 1908) gives the result of the examination of 100 consecutive cases of eczema occurring during the first year of extra-uterine life. He finds that about four-fifths of the cases occur during the first four months of life, and that male children are much more commonly affected than female, the proportion being 78 to 22 per cent. The disease is much more common during the colder months of the year than during the summer, only 7 of the 100 cases began during the months of June, July and August. He finds no evidence of vaccination as an ætiological factor, the number of cases in which it follows that operation being less than one-third of the whole. In over four-fifths of the cases, also, the first dentition had not begun when the rash first appeared. The primary site of the eruption is almost always on some part of the scalp or face, and it always becomes bilateral and usually symmetrical. The disease is usually most severe in or about the region of the primary site. Hall is of opinion that "such a uniformity of primary situation at least suggests a diminished local resistance to the ordinary external irritants of daily life." There does not appear to be any particular local irritant, but "the fact that only 7 per cent. of the cases began during the summer quarter seems to support the view that exposure to cold winds may be the common external irritant." K.

Veronal Dermatitis. — Ormsby (*Cleveland Med. Journ.*, Jan., 1908) reports a case of this rare form of drug eruption. Only some eight or nine cases have been recorded since the drug was introduced by Fisher in 1903. In some of these cases the eruption was vesicular or pemphigoid, and in others consisted merely of an erythema. Ormsby's patient was a woman, æt. 54, suffering from varicose veins of the legs. She was ordered two 5-grain doses of veronal in the day to procure sleep, and about five days later became feverish, and had some itching of the skin, especially between the fingers and toes, and on the dorsal surface of the hands and feet. The fever continued, and she became delirious. The dermatitis spread to the arms, legs, trunk and face, and was accompanied by considerable œdema, redness and itching, but there does not appear to have been any development of vesicles or bullæ. The whole condition of the patient resembled that of an acute attack of general erysipelas. The inflammation generally subsided, and had entirely disappeared in six days, but was followed by extensive desquamation. The nails also became black and brittle, and were eventually shed. K.

Lack of Gastric Mucus and its Relation to Hyperacidity and Gastric Ulcer.—Kaufmann (*Amer. Journ. of the Med. Sciences*, Feb., 1908) contributes an interesting article on this condition, which he considers a very important factor in the production of diseases of the stomach. In order to recognise the absence of mucus from the gastric secretion, it is necessary to examine the contents of the stomach after a test breakfast. The absence of mucus may then be recognised macroscopically by finding the particles of bread more or less finely divided, distinctly separated, and forming a flour-like layer from which the watery constituents of the test meal quickly separate. This finding can be confirmed by staining with Lugol's solution, which does not mix with the mucus. If mucus is absent, all the starch grains and yeast will be stained, but if mucus be present in normal quantity, most of these particles are protected from the stain. The mucus is to be looked on as a protection to the gastric mucosa. If the gastric juice is of low acidity, the lack of mucus will not cause any symptoms, but if the acidity is normal or increased, severe symptoms of gastric irritation will follow. In this way Kaufmann explains those cases which present the symptoms of hyperacidity, but in which the gastric secretion shows no excess of acids. Treatment by lavage with solutions of silver nitrate quickly relieves the symptoms of hyperacidity, but in many cases so treated it was found that after the symptoms had completely disappeared the hyperacidity of the gastric juice was not really lessened. A marked increase in the mucus present was, however, always found in such cases after the treatment. Kaufmann concludes that, "without sufficient covering of mucus the gastric mucosa becomes more easily injured by the many insults to which it is constantly subjected. When once injured, even though slightly, the damaged part becomes more prone to the invasion of bacteria and to the digestive action of the gastric juice. Again, the thinner the layer of protective mucus the easier will these secondary deleterious insults to the injured mucus membrane take effect. Under such conditions the digestive activity of the gastric juice must be particularly pronounced when hyperacidity is present. It is probable that such occurrences are the primary disturbances in the development of gastric ulcer. The majority of cases of gastric ulcer give a history of a more or less prolonged period of suffering from so-called hyperacidity symptoms." K.

The Army and Navy Male Nurses' Co-operation (which is under the patronage of Her Majesty the Queen, and was founded by Miss Ethel McCaul) has taken the Caxton Hall, Westminster, for the purpose of holding "The World's Jumble Sale" on May 22nd and 23rd next. This will afford an opportunity to all, and especially the women of the country, of assisting this most deserving Institution, and this they can do by presents of second-hand articles useless to themselves but of great value to those organising the sale. The Sale Secretary (Miss I. Crowdy) will be most pleased to send a collecting sack for such presents on receipt of a card desiring her to do so, addressed to the offices, 47b, Welbeck Street, W.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

H. G.—The Paris Courts recently decided that no legal responsibility rests upon a medical man in respect to warning a patient to whom an anæsthetic is about to be administered that, in a certain number of cases, a fatal result ensues from the anæsthesia.

As Influenza (so-called) is now so prevalent, a few lines on the subject from a victim might be found appropriate:—

A VICTIM'S EXPERIENCE OF INFLUENZA.

When your sitting in your tub, only gruel for your grub,
And your head feels like a beehive all the time,
And you cannot sleep a wink,
And you think, and think, and think,
And imagine you are punished for some crime!
And you wonder what comes next,
And with everything you're vexed,
And you're thinking what the deuce is wrong with you,
And your eyelids feel like lead,
And you're bound to stay in bed,
You've got a jolly dose of what's *called* "Flu" ! A. D.

C. B. T., M.D.—We are sorry about your letter, but do not remember receiving it, and can find no reference to it. We think you will admit that the views you support are not those of the bulk of the profession, nor are they our own. And we hope that we are not unfair, even when we think it right to speak emphatically.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, FEBRUARY 26TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Prof. D. Armour: The Surgery of the Spinal Cord and its Membranes. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. L. Mummery: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. L. Paton: The Retina in Albuminuria.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Outpatients Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

THURSDAY, FEBRUARY 27TH.

CHILD STUDY SOCIETY, LONDON (Parkes Museum, Margaret Street, W.).—8 p.m.: Sir Edward Brabrook: Introductory Address.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. F. Taylor: Leukæmia.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappell). 4.30 p.m.: Lecture:—Dr. A. G. Auld: Asthma, its Pathology and Treatment.

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Baldness, its Causes and Treatment.

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Mr. Fairbank: Surgical Treatment of Paralyses.

THE THROAT HOSPITAL (Golden Square, W.).—5.30 p.m.: Mr. Parker: Chronic Inflammatory Affections: Treatment.

FRIDAY, FEBRUARY 28TH.

ROYAL SOCIETY OF MEDICINE (EPIDEMIOLOGICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Mr. R. C. Punnett: Mendelism in Relation to Disease.

ROYAL SOCIETY OF MEDICINE (ELECTRO-THERAPEUTICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Dr. L. Jones: The Principles and Practice of Ionic Medication.

ROYAL SOCIETY OF ARTS (John Street, Adelphi, W.C.).—8 p.m.: Dr. J. S. Haldane: The Removal of Dust and Fumes in Factories (Shaw Lecture on Industrial Hygiene.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Prof. D. Armour: The Surgery of the Spinal Cord and its Membranes. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Dr. J. Horne: Clinique. (Throat.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—3.30 p.m.: Lecture:—Dr. C. Beale: Ulcerative Endocarditis or Cases of Interest in the Medical Wards.

MONDAY, MARCH 2ND.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Prof. F. C. Shruball: The Physical Antropology of the Pigmy and Negro Races of Africa.

THE THROAT HOSPITAL (Golden Square, W.).—5.30 p.m.: Mr. Faulder: Diseases of the Perceptive Mechanism: Acute.

Appointments.

CURTIS, HENRY, B.S., M.D.Lond., F.R.C.S.Eng., Assistant Surgeon at the Branch Seamen's Hospital, Royal Albert Dock, E.

LEITCH, ARCHIBALD, M.B., Ch.B.Glasg., Investigator into Cancer in connexion with the Dundee Royal Infirmary.

SHAW, JOHN EDWARD, M.B., C.M.Edin., Honorary Consulting Physician to the Bristol Royal Infirmary.

SIMPSON, GRAHAM, F.R.C.S.Eng., Clinical Tutor in Surgery at the University of Sheffield.

SMITH, E. ARCHIBALD, M.B., F.R.C.S.Eng., Honorary Surgeon to the Western General Dispensary, Marylebone Road, London, N.W.

TURTLE, GODFREY DE BEC, M.D., B.S.Durh., M.R.C.P.Lond., Physician to the Public Dispensary, Drury Lane, W.C.

WETHERALL, PRITZLER SIM BATTEN, L.R.C.P.Lond., M.R.C.S., Medical Officer for the Weymouth Workhouse.

Vacancies.

Liverpool Dispensaries.—Assistant Surgeon. Salary, £100 per annum, with board and apartments. Applications to the Secretary, 56, Vauxhall Road, Liverpool. (See Advt.)

County Borough of Middlesbrough.—Education Committee.—Medical Inspection of School Children.—Assistant to the Medical Inspector of School Children. Salary, £300 per annum. Applications to J. S. Calvert, Secretary, Education Committee, Municipal Buildings, Middlesbrough.

Barnsley Hall Asylum, Bromsgrove, Worcestershire.—Second Assistant Medical Officer. Salary, £150 per annum, with furnished quarters, board, washing, and attendance. Applications to the Medical Superintendent.

Lanark County Council.—Bacteriologist. Salary, £250 per annum. Applications to the County Medical Officer, Hamilton.

Plymouth Education Authority.—School Medical Officer. Salary, £250 per annum. Applications to E. Chandler Cook, Secretary, 18, Princess Square, Plymouth.

Manchester Royal Infirmary and Dispensary.—Honorary Assistant Gynæcological Surgeon. Applications to the Secretary. (See Advt.)

Metropolitan Asylums Board, London.—Assistant Bacteriologist. Salary, £300 per annum Applications to the Clerk, Metropolitan Asylums Board, Embankment, London, E.C.

Births.

BUCKNALL.—On Feb. 20th, at 16 Devonshire Street, Portland Place, London, the wife of Rupert Bucknall, M.S., M.D., Lond., F.R.C.S., Eng., of a son.

HERRINGTON.—On Feb. 21st, at 18 Lorrimore Square, Kennington Park London. the wife of Edmund W. Herrington, L.R.C.P., M.R.C.S., L.S.A., D.P.H., of a daughter.

STRATFORD.—On Feb. 20th, at 210 Worple Road, Wimbledon, the wife of Howard M. Stratford, M.R.C.S., L.R.C.P., of a son.

Marriages.

BRERETON—BAKER.—On Feb. 20th, at Manchester Cathedral, John Neville Brereton, N.M.A., to Florence May Baker, younger daughter of the late Benson Baker, Esq., M.D., L.R.C.P., of London.

DARTNELL—GILMOUR.—On Feb. 22nd, at St. Michael's, Mickleham, Surrey, Staff Surgeon Louis E. Dartnell, R.N., to Margaret Ethel, third daughter of the late David Gilmour and Mrs. Gilmour, Mickleham Downs, nr. Dorking.

FELCE—STRATTON.—On Feb. 21st, at Christ Church, Winchester. Gilbert Carlyon, youngest son of Stamford Felce, M.R.C.P., M.R.C.S., of Cope Hall, Newbury, to Hilda, daughter of Frank Stratton, J.P., of Manningford-Bohnne, Wilts.

Deaths.

BARNES.—On Feb. 20th, at Sunningdale, West Worthing, Robert Sydenham Fancourt Barnes, M.D., F.R.S.E., of 15 Chester Terrace, Regent's Park, aged 59.

BELL.—On Feb. 22nd, at 17 West Southernhay, Exeter, Blanche Noble, the beloved wife of Charles E. Bell, M.R.C.S., L.R.C.P.

HARLEY.—On Feb. 21st (suddenly), Robert William Harley, M.D., of 31 Pembroke Road, Dublin, aged 67.

NORMAN.—On Feb. 23rd, at his residence, S. Dymphna's, N.C. Road (suddenly, of heart failure), Conolly Norman, F.R.C.P.I., Resident Medical Superintendent Richmond Asylum, fifth son of the late Rev. Hugh Norman, aged 54.

Pneumonia, Pleurisy, and Sequelae.

The administration of Angier's Emulsion during and after attacks of Pneumonia or Pleurisy is based upon sound, logical and scientific reasons. To combat the exhaustion attendant upon these diseases is the first thought in treatment. What more rational method of doing this than by supporting the patient with nutritious food, and the administration of a remedy that assures its perfect digestion and assimilation, and its conversion into the nutritional power that is Nature's own weapon against the ravages of infection of any character? Angier's Emulsion has this effect and more. Its sedative irritation-allaying influences upon inflammatory affections of the respiratory organs are simply unique. It relieves the pulmonary distress, the hacking cough, the difficult expectoration of Pneumonia and Pleurisy with a rapidity and completeness that are, at times, surprising. After the battle—when the disease has run its course—and the nervous system, the patient's nutrition and vitality are at the lowest ebb, try the continued use of Angier's Emulsion for a convincing proof of its effects as a tonic, and reconstructive of blood, tissue and vitality.

THE TUBERCULOSIS PROBLEM.

Given the Sociological Conditions of Sanatoria and Medico-Dietetic Conditions of "MIOL," there is evidence arriving daily from medical men that MIOL will satisfactorily combat tubercular Disease.

"Miol"

"MIOL" IN PULMONARY DISEASE—The air passages are relieved from the obstructive morbid secretions; breathing is soon restored to the normal. Hæmoptysis is at once arrested, night sweats stop in about three days, the irritating cough is speedily removed.

The foul-smelling septic condition is corrected by the antiseptic action of the contained free Iodine, and the whole series of morbid symptoms are removed.

"MIOL" is a nutritive tonic and stimulant promoting the functional activity of all the organs of the body as well as being the most active digestive of its kind known to Science.

MOST PALATABLE. CHILDREN LIKE IT.

"MIOL" is being rapidly established in all the principal Hospitals and Sanatoria.

Send for booklet and sample with actual Clinical Reports obtained by Medical Men from Patients.

Will the Doctor kindly—

(1) Weigh each case before taking "MIOL," and each fortnight afterwards?
(2) Examine the sputa and blood before and after taking "MIOL" for Tubercle Bacilli?
(3) Note temperature, sweating, appetite and digestion before and after beginning "MIOL" from time to time?

Samples and Clinical Reports on application.

"A distinct advance on Easton's Syrup."

—*The Lancet.*

"Bynin Amara"

'BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION.

Quinine Phosphate	1½ grains.
Iron Phosphate	2 ,,
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$,,
'Bynin, Liquid Malt	1 ounce.

DOSE FOR ADULTS—One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

Disposal of the balance of 13,300 dozen Chateau Lafite. (The greater part was disposed of shortly before the Summer holidays, during which this sale was not advertised.)

Ehrmann Brothers'

43, 44, & 47, Finsbury Square, London, E.C.

INTERESTING SALE

An unprecedented purchase by any one purchaser—viz., the whole of a vintage in bottle.

13,300 DOZEN

Of the Premier Chateau Claret, the famous

Chateau Lafite 1890 Vintage.

(The 1er Cru Classe in the official classification.)

GROWTH OF BARONS DE ROTHSCHILD.

FULL BRAND on CORKS, CAPSULES, LABELS, and CASES.

CHATEAU LAFITE
PAUILLAC
GRAND VIN 1890
Barons de Rothschild
PROPRIÉTAIRES

12,100 Dozen Per Dozen

1890 CHATEAU LAFITE "GRAND VIN," fully Branded **29/6**

800 Dozen

1890 CHATEAU LAFITE "CARRUADES," fully branded, body equal to the "Grand Vin" bouquet a shade less pronounced **27/6**

400 Dozen

1890 CHATEAU LAFITE "2me VIN," fully branded, beautiful bouquet, a shade lighter than the "Grand Vin" .. .. **SOLD**

Price for the Continent and for Export fr.2.50 per bottle free on rail or export ship "Bordeaux"

Thus the Premier Claret (the Chateau Lafite) of a class **usually sold at about 84/0** per dozen **is now offered by us at less than 2/6 per bottle.**

An allowance of
6d. per doz. on from 12 doz. to 29 doz., and
1/0 „ „ 30 doz. and upwards will be made.

Never before was such an opportunity offered to Connoisseurs to acquire a Wine of this famous growth and of such quality and with complete guarantee as to authenticity at so low a price. Admirers of fine Claret should not miss this opportunity, which is not likely to occur again.

The Barons de Rothschild, the Proprietors of the famous Chateau Lafite, did not, during the greater part of the 'eighties, permit any bottling at the Chateau; but the superior 1890 Vintage was bottled for them with full brand on corks, and held in a special cellar, small quantities only having been parted with.

The Wine was bottled in greatest perfection, is in splendid condition, showing its great breed and style, possessing fine colour, beautiful bouquet, great elegance, and matured fruitiness. It is very soft and mellow, and a most superior dinner and dessert Claret of best style.

In sympathy with the movement to assist the undoubted revival in taste for high-class Claret, the holders have been prevailed upon to sell, and **we have purchased the whole existing quantity** of this excellent Wine at a most reasonable price and have been placed in a position to offer it at the above nominal and most moderate rates, far below its true value and less than half the usual selling price of this growth and quality.

Quantity required. M.P. **ORDER FORM** Per doz. £ s. d.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, MARCH 4, 1908. No. 10.

NOTES AND COMMENTS.

The Licensing Bill.

THE question that medical men will set to themselves about the Licensing Bill introduced in the House of Commons last week, will be: Is it a measure that will make for the increased sobriety of the nation? If they are able to answer it in the affirmative, the Bill will be very welcome; but if they conclude the measure is mere "window-dressing" it may well be left to fight its way through the stormy arena of politics. Drunkenness and drinking are the prime cause of, and constitute the most important ancillary features in, an enormous number of diseases, and it is within the truth to say that national longevity would be prolonged, illness much more infrequent, and many diseases entirely banished, if there were no such thing as alcohol. It is, however, one thing to recognise a disease and another to prescribe a remedy. There is much to be said for the view that is is impossible to legislate a man into temperance if he is alcoholically inclined, and quite a body of opinion in favour of Dr. Archall Reid's suggestive, but pessimistic, theory that a people has to pass through a stage of energy and drunkenness before it reaches one of nonentity and sobriety. In our view, drunkenness is a symptom expressing social unrest and discontent, that is to say, alcohol is used as an anæsthetic for the woes, physical and mental, of life, and the indication is to deal with the causes lying deep in our system of civilisation which produce the symptom. The Licensing Bill, if it passes, will provide an experiment which will be watched nowhere with more interest than in the out-patient departments of hospitals and among those who attend many of the poor.

The L.G.B. and Carlisle.

WE have had occasion lately—and good occasion—to criticise the attitude of Mr. John Burns in regard to the medical profession, namely, when he, himself a staunch Trade Unionist, imposed an invidious obligation on medical men, and urged them to rise higher than their Trade Union. It is, therefore, with all the more pleasure that we notice an act of his which shows an appreciation of the services of medical men to the public health. The Town Council of Carlisle recently determined to have a whole-time Medical Officer of Health, and offered the ambassadorial salary of £400 a year to the successful applicant. The President of the Local Government Board, however, promptly wrote and intimated that the Board would not sanction the arrangement unless a salary of £500 were supplied, because it is necessary to secure for medical officers "such a position as will enable them to perform their duties impartially and independently," and also because it is desirable that they should not be regarded as holding "an inferior position as compared with other medical men." This is wholesome doctrine and from the right source.

Penny Wisdom.

THE evolution of the Public Health Service is slow, and it certainly is not taking place altogether in the right direction. Sanitary authorities, it is true, are inclining more and more to the "whole-time" principle, which is the only logical one for a medical officer to hold if he is to be independent and impartial, but the salaries offered are so small that these posts cannot continue to attract the best class of man. It is hardly to be expected of human nature that the most intellectual and energetic men in the profession will continue to apply for posts, mostly held on uncertain yearly tenancies, and all without pension, when they can earn £1,000 a year and upwards in general practice. Young men may take the smaller sum when there are prospects of promotion, but the tendency is for £600, £700, or £800 a year to be made a top price. If counties and large towns do not offer more than those sums, the result must be that men will see how little there is to hope for in the public health line, and only mediocrities, or those below even that standard, will apply. Considering the paramount necessity for thorough development of public health administration if the community is to prevent the many evils of civilisation, money laid out on the best advice may be regarded as the best investment Society can make, and is it really asking too much to suggest that the Medical Officer of Health should be paid not less than the Town or County Council Clerk?

Vaccination Fees.

THE revised scale of vaccination fees is being put into force by various Boards of Guardians, and a good deal of discontent is naturally evinced by public vaccinators. We confess to considerable sympathy with them. The question is not one of the efficacy of vaccination, or the policy of primary vaccination for infants, but simply one as to whether the fees are sufficiently liberal to remunerate practitioners holding the appointment of public vaccinator. It is merely stupid to expect vaccinations carried out with elaborate precautions, and done at a patient's home, to be paid for on anything like the old scale when "stations" were in vogue, and a vaccinator could vaccinate a score or two of children in an hour or so a week. The idea is even more preposterous when the elaborate book-keeping and correspondence entailed by the new plan is taken into account. The benefits now received by the public must be paid for, and naturally the cost of vaccination has risen considerably, to the chagrin of the noisy section which hates vaccination and all its works. It is, however, but fair to remember that the accidents of the operation are reduced to minimum by the new plan, and it is essential in the interests of the community that this high level of efficiency should be maintained. Moreover, a public vaccinator is always a private practitioner, and the demands made upon him in his official capacity vary enormously. He is not allowed to vaccinate by deputy, at least to any considerable extent; and in periods of threatened epidemic the whole of his private practice is dislocated by the rush of applicants for vaccination. One man is only capable of doing a certain amount of work, and what he receives in fees from the guardians he probably loses in private connection. Cheese-paring boards must take these facts into consideration.

Free Medical Advice.

IT would be interesting, but presumably impossible, to obtain an authoritative census of the number of people who obtain their doctoring for nothing, and of those who obtain it for nothing in all cases of serious illness. The *Newcastle Journal* the other day pointed out that in that city there were no less than thirty institutions for the relief of the sick poor, and propounded the question, "How many fewer than two-thirds of the Newcastle sick get medical aid for nothing—medical aid at the expense of the ratepayers and the charitable?" Like Pilate's query of old, we fear this question is likely to remain possessed of a higher suggestive than intrinsic value; but it is interesting that a lay journal should have been so much struck by the phenomenon of wholesale medical relief as to submit the proposition to its readers. No one grudges gratuitous medical help to the genuinely unfortunate in the battle of life, and it is certainly better that a few rogues who can afford to pay should be seen for nothing than that a deserving case should be unattended. But there are limits to the time of medical men and economic limits to the practice of seeing all applicants who put in an appearance at hospitals, and the probability is that there is a very small percentage of the poor who could not make some definite provision for sickness, if it were brought to their knowledge that they were expected to do so.

A Needed Inquiry.

IN London the Prince of Wales has been well advised to decide on appointing a committee to inquire into the "system" of admitting and treating out-patients at the various hospitals, for there is probably no city in the kingdom where more abuse takes place, and where the working classes contribute so little to the hospitals. The actual appointment of the committee is postponed till the Royal Commission on the Poor Laws has reported, for it is thought with good reason that otherwise a good deal of the work of the two bodies would overlap; but we warmly welcome the idea of such a committee, and we are sure it will have the support of all hospital reformers. The utter chaos existing in the hospital world is a reproach to civilisation. Anybody goes to any hospital at any time, and demands relief on the spot, knowing that he cannot be refused treatment, even if the injury is a pinprick or flea-bite. If hospitals were attached to certain areas, and only people living in that neighbourhood were entitled to relief, there might be a chance of eliminating the unworthy, but as things stand now there is no satisfactory method of dealing with impostors, and some, as is well known, make the tour of the hospitals getting for considerable periods medicine from all and a bed at some. It is much to be hoped that the committee will report in favour of out-patient departments being made purely consultative, such as is the case now at the Belgrave and Bolingbroke Hospitals, except, of course, in the case of emergencies. And even the "emergency" consultation is liable to many abuses. There is no reason why a workman or butcher who cuts his hand should have it dressed for nothing at a hospital. All works at a distance from hospitals have their own "first aid" men, and it is the obvious duty of those near to make similar provision. There is a greater want of comprehension as to the function of hospitals than of almost any other public institution.

LEADING ARTICLES.

QUACKERY IN AUSTRALIA.—No. 1.

UNDER all climates and in all races there is to be traced a community of intellectual habit that probably springs from a single ancestral origin. One of the many interesting problems that presents itself to the philosophical student of sociology is the universal patronage bestowed by mankind upon quacks and quackery, no matter how well supplied they may be with medical practitioners duly qualified and equipped with the best modern knowledge. The man in the street, whether in London, New York, Cape Town, Yokohama, Pekin, Madrid, St. Petersburg, or where you will in scores of nations, prefers the confident assurance and promises of the quack to the guarded probity of the responsible medical man. It seems doubtful whether the general spread of education will remedy this defect in human judgment. Some of our greatest philosophers have been given over to the toils of the nostrum vendors, and it is well known that in the House of Commons it would have been hopeless to introduce legislation against irregular practice during the lifetime of a notorious bonesetter who departed this life some years ago. In the United Kingdom for some time past, Mr. H. Sewill, adopting the policy for many years advocated in THE MEDICAL PRESS AND CIRCULAR, has strongly advocated the appointment of a Royal Commission to ascertain the nature and extent of the evil of quackery. This certainly appears to be a necessary and logical step which will furnish both legislators and citizens with a mass of trustworthy evidence upon which a sound opinion may be based. Australia has been before us in this matter, as we are reminded by the appearance of the first volume of the Report of the Royal Commission on Secret Drugs, Cures, and Foods. The scope of the inquiry is stated to be: (*a*) The manufacture, importation, announcements, offering for sale, sale, and use of preparations commonly known as patent or proprietary medicines and of drugs, alleged curative agents, medicinal preparations, toilet articles, foods, and drinks, the composition of which is not disclosed, and which are alleged to have medicinal or remedial qualities; (*b*) the effects or consequences of the use of such articles; and (*c*) the legislation and administration in Australia and elsewhere relating to any of the aforesaid matters. The subject under investigation has been divided into six chapters or divisions, namely, prevention of conception and fœticide; infanticide; injury and death to the adolescent; injury and death to adults; advertisements, and legislation. An immense mass of matter has been collected under these various headings, and in many instances the advertisements themselves are produced in facsimile. To attempt anything like an analysis in a leading article would, of course, be out of the question, but in future articles we shall hope to deal with further details. Speaking of drink cures, the Report observes that drunkards, like other afflicted persons, are choice game for swindlers. Many fraudulent secret cures are herein set forth, and a host more are thrust forward upon the public, or, rather, upon the self-denying friends of the inebriates, thus causing much grief and ruin. The pith of the matter is arrived at in the terse proposition that, "if there be merit in the cures there should be no secrecy; if there be secrecy it is incredible that there should be merit." "Drink cures" have always been strongly attacked in our own columns, so that the emphatic condemnation offered in the Australian Report comes with an exceptional claim upon our attention. The cruelty of many of these preparations, specially aimed at women, lies in the fact that they are largely made of cheap white spirit, and are consumed by way of private debauchery. One form of bitters, for instance, is made up with spirit to half the strength of whisky. It seems almost incredible that a preparation which has a wide sale as a cure for kidney disease should have nine-tenths of the strength of whisky. The Bile Bean case is fully discussed, and some astonishment is expressed that, after the unsparing condemnation of that preparation by Lord Ardwell in the Court of Session of Scotland, in 1905, there is no suggestion for stopping the sale, no suggestion that the State should cease to participate in the total receipts by its average share of one-eighth, no suggestion, as a matter of course, that any punishment should follow. It is to be noted that most of the secret preparations exposed and condemned by the Australian Commission flourish in the United Kingdom. If the General Medical Council be in earnest in their recent pious resolution with regard to quacks and quackery, they will find an immense quantity of material at their hands in the Australian report. It is shown therein that every range of therapeutic knowledge has been ransacked. At the end of a long classification it is added naïvely: "The foregoing list is incomplete in itself, and to it must be added—an interminable series of quack secret cure-systems, which is being ever augmented. These embrace everything conceivable in health and in disease under like trickery, treachery, humbug, and fraud. They are not subject to preliminary examination, license, and inspection. Though these humbugs are notorious and often ridiculous, prosecutions are either rare or entirely absent." In our next issue we propose to deal with some of the conclusions and recommendations presented in this important Report. It is to be hoped that before many years have elapsed a similar volume may be issued by the legislature of the United Kingdom.

THE TUCKER ASTHMA CURE AGENT FINED.

Hardly have the reverberations of the recent libel case, Tucker *versus* Wakley died away, than the agent (or proprietor) of that "cure" again figures prominently in the public gaze. This time he has been prosecuted for selling "certain poisons, to wit, cocaine and atropine, contained in a bottle bearing the words 'Nathan Tucker, M.D., specific for asthma, hay fever, and all catarrhal diseases of the respiratory organs,' which bottle, when sold, was not distinctly labelled with the word, 'poison,' and with the name and address of the seller." In support of this precise, if not elegantly worded charge, Mr. Thomas Tickle, public analyst, stated the fluid in the bottle contained 3.6 grains of cocaine, and .91 grains of atropine. It appears that the purchaser went to the house of Mr. Augustus Q. Tucker, at Herne Hill, and asked him for a bottle of his specific. He further explained, in answer to a question, that he wanted a one-ounce bottle, which was handed him by the defendant without further ado, paid for, and the customer walked away. Medical evidence showed that the contents of the bottle, if swallowed, would probably cause death. The bottle appears to have had no label or attached directions. For the defence it was alleged that it was Mr. A. Q. Tucker's practice to send out the bottle with minute instructions that it was to be used only as an inhalant. The defendant, through counsel, further stated that until quite recently, he was totally unaware of the ingredients of the specific, which represented an extremely valuable professional secret, the discoverer being his brother, Dr. Tucker, a distinguished American physician, for whom he acted as agent in this country. In the upshot, a fine of £5 and £5 5s. costs was inflicted. The result will serve as a reminder to all concerned in combating the evils of the patent medicine trade, that there are various methods by which action can be taken. Where the ingredients of such preparations contain deadly poison, a prosecution can always be undertaken, unless the word "poison" is printed legibly across the label. The presence of such a precautionary warning would certainly render many persons more chary in resorting to a palpably dangerous remedy. The glimpse behind the scenes afforded by this prosecution, apart from its serious significance, is worthy of the pen of a Dickens. An American gentleman, one of whose Christian names we understand, is "Quackenbusch," drives a huge trade in an American specific for asthma. In the United Kingdom there is a stringent Poisons Act for the protection of citizens. A number of active poisons are carefully scheduled, and a customer wishing to purchase any of these poisons must go to a qualified chemist, and satisfy him as to *bona fides*, and have careful entries made as to the details of the transaction in a book kept specially for that purpose. The American nostrum agent, however, is not hampered by any considerations as to the possibility of collision with the Poisons Act. By his own confession he does not even trouble to inform himself as to the nature of the drugs which he is distributing broadcast, for it has been shown in evidence that a large trade existed in this American "specific." The irony of the whole situation is evident to the medical profession, who know that asthma is a symptom due to various causes, for some of which it would be hopeless to expect cure from powerful drugs applied to the nasal mucous membrane. That aspect of the question was taken up rigorously by the *Lancet*, who have had to pay the penalty for their assumption that the law would demand that the vendor of a nostrum should substantiate scientificially the therapeutic claims advanced by him on behalf of his specific. We fear that our distinguished contemporary will glean but cold comfort from the reflection that it has been a generation in advance of the times. On the other hand, its public-spirited action has earned the sympathy and respect of all interested in the true welfare of legitimate medical science.

CURRENT TOPICS.

Bravery and Hypnotism.

THE Westminster Coroner recently had occasion to eulogise in the warmest terms the promptitude and bravery shown by a lady doctor. A cook in a certain house had the misfortune to set fire to her clothing, which a carpenter and a manservant tried in vain to extinguish. At that point Dr. Ettie Sayer appeared on the scene, threw the unfortunate woman down on the ground, and promptly extinguished the flames with the aid of a rug. The subsequent inquest revealed the fact that the cook was dressed in the fatal flannelette. A neighbouring medical man, who was called in, applied hypnotism without avail, for the poor woman died soon afterwards as the result of her injuries. We do not recall the use of so unusual a therapeutic agency as hypnotism under similar circumstances, nor could it be imagined that such a proceeding is likely to meet the approval of the medical profession generally. Were similar treatment to be applied by an unqualified person he or she would be liable to prosecution. As to the flannelette its use for articles of dress should, in our opinion, be forbidden. As to Dr. Ettie Sayer, she deserves honour at the hands of the profession as well as of the public. We should be pleased to organise a testimonial.

Chemist as Medical Man.

THE Cardiff Coroner, Mr. W. L. Yoratto, certainly has the courage of his convictions when called upon to deal with unqualified medical practise. A plumber's wife of the town took her three-year-old child to the shop of a chemist, where an assistant said the sickness was influenza, and gave a bottle of physic. As a matter of fact the disease was diphtheria, which proved fatal a few days later. As every medical man knows, the early recognition of diphtheria is essential to any fair chance of cure. On the other hand, it is well-nigh impossible to diagnose influenza in a baby, so that on all accounts the amateur doctor could not have chosen a more unfortunate case for the exercise of his fatuous diagnosis and fateful treatment. The Coroner pointed out it was the duty of the chemist to dispense and not to prescribe, and the case should serve as a warning against chemists treating disease, and to all people to call in a doctor rather than to risk life in that way. Surely some further action should be taken by the police or by some other bodies concerned in this gross violation of public interests. The medical man called in during the later stage of the disease said in so many words that the child probably would not have died had she been taken to a medical man instead of to a chemist. There is no need to emphasise the significance of that exceedingly strong and apposite statement.

Medical Men and the Civil List.

THE case of Dr. Hall Edwards, the well-known radiographer, who has recently lost his arm through prolonged exposure to the X-rays and consequent dermatitis, has recently been brought to the notice of His Majesty King Edward. It was suggested that he would be a fit recipient for a civil pension. A letter of sympathetic appreciation has been returned, pointing out that the more regular course for such an application would be through the Prime Minister. Although we cannot recall any instance in which the disablement of a medical man sustained in the exercise of his profession has been recognised by a pension, we can, nevertheless, imagine no more worthy recipient for the bounty and gratitude of the nation.

Delusions in Court.

THE proceedings of police courts now and then suggest obvious insanity on the part of prosecutors or defendants, a fact that does not appear to have suggested itself to anyone concerned. In the coroner's court the mental condition is kept more in view, and miscarriages of judgment are not so likely to happen. A curious case of delusions in father and son came before the Hackney Coroner last week. The inquest was held upon the body of a man who was said to have been killed by flames emitted from a telephone receiver. The chief witness was a son of deceased, who stated with detailed emphasis that the breath was drawn out of his father's body by a flashlight from the National Telephone Company. Death was caused, in his opinion, by a complicated system of wires. Another son stated that he had heard his father speak of the flashlights, but had never seen them himself. The whole evidence of the former witness reads like a page from an asylum record. A curious point about the incident is that possible danger from telephone receivers has been suggested. In more than one instance fires in the City of London have been traced to contact of telephone wires with "live" conductors of electric railways. The danger of electricity conducted by wires is a form of delusionary insanity familiar to all who have to deal with mental disease.

The Proposed Taxation of Motor Cars.

IT is strange that at the present moment, when the further taxation of motor-cars is being so generally suggested, it is apparently left to the lay journals to suggest that motor-cars belonging to medical men should be treated as the shepherd's dog and allowed to escape taxation. Moreover, as far as we know, not one of the various bodies who are supposed to guard medical interests have taken any steps to place their views on this important subject before the Chancellor of the Exchequer. The only person who appears to have taken any interest in this particular question is Dr. J. J. Lock, who attended with a deputation from the Motor Union and addressed the Chancellor on the part of medical men. His action in this respect was most commendable, but still it cannot have the weight which it would have if he had come as the representative of the profession generally. Apparently the medical profession are quite content to submit to the infliction of an extra tax from which an organised effort could deliver them. Their action in this respect is similar to their action, or, rather, to their want of action, regarding the new regulations of the Telephone Company, which by a stroke of the pen has imposed an extra expense for telephones on medical men amounting to many thousand pounds annually. What is the use of having a costly mechanism worked by a large and wealthy representative Association if it is not brought into action in cases such as these? At the present moment we find that the profession has already been mulcted to a very considerable extent in respect of its telephones, and that it will shortly be taxed in respect of what is becoming its most important means of locomotion, and yet no protest is made!

Medical Men and Night Calls.

Our notice has been drawn to a somewhat curious letter addressed by a lay correspondent to the editor of a leading East Anglian newspaper. The writer details two cases in which a medical man, summoned hastily in the night time, declined to attend a patient. He further extols, by method of the "puff oblique," the zealous promptitude and humanity of another practitioner, who at once attended in both instances, and we can imagine the embarrassed anger and annoyance of the latter gentleman upon finding his name thus freely advertised. The correspondent winds up with the usual query as to "whether doctors have any legal right to refuse to attend to such cases of urgency, without apparently any adequate cause?" An equally pertinent inquiry is whether patients have any right to summon a medical man at any time, night or day, unless they are prepared then and there to pay him an adequate fee. With advancing experience of the rough and tumble of general practice, the medical man becomes more and more chary of going out at night to chance calls, in which he has long since learnt there will be little or no chance of any remuneration. There are limits to human energy, and he finds it necessary in the interests of his wife and family, not to mention his own health and the requirements of his other patients, to secure some amount of sleep. The young practitioner for the first few years of practice is keen to attend everything, night or day, regardless of fees. We wonder if the public ever knock up the quacks and prescribing chemists in the night, and, if so, what sort of response is made as to fees and attendance.

A Judge and Public Health.

We have from time to time heard complaint of the practice existing in Ireland of judges delivering speeches at the opening of their courts on matters they deem of public importance. We could wish, however, that some of his learned brethren would follow the excellent example set by the Honorable the Recorder of Dublin last week. Speaking with a due sense of responsibility, the Recorder drew attention, not for the first time, to the deplorable condition of the housing for the working poor of Dublin. The crowded slums were the spawning-ground, not only of intemperance and crime, but also of diseases of all kinds, and specially of tuberculosis. "The subject," he said, "affected both the moral and physical health of the citizens, and for them was not second to any other. He regarded the condition of the housing of the workers and the poor as a gruesome monument to neglect of civic obligation." The charge made in solemn language from the judicial bench is one often made in these columns. The responsibility lies with the health authorities of Dublin, who hitherto have shown no due sense of the magnitude of the evil resulting from their neglect. It is possible that the Recorder's grave rebuke may have some effect in rousing public opinion. For himself the attitude he has adopted is worthy of the best traditions of his ancient and honourable office.

PERSONAL.

Professor J. A. MacWilliam has been elected Honorary President of the Aberdeen University Medical Society.

M. Ribemont-Dessaignes has been appointed Professor of Clinical Obstetrics in the Faculty of Medicine of Paris.

Dr. Comyns Berkeley and Dr. Herbert Williamson have been elected physicians to in-patients at the City of London Lying-in Hospital.

Dr. Duncan Forbes, Medical Officer of Health of Cambridge, has been selected for the post of Medical Officer of Health for Brighton, in succession to Dr. F. Newsholme.

Dr. H. Campbell Thomson, M.D., F.R.C.P., has been elected Dean of the Medical School of the Middlesex Hospital, vice Mr. John Murray, F.R.C.S., who has resigned after holding the office for six years.

Dr. F. M. Sandwith, Gresham Professor of Physic, is giving four lectures at Gresham College, Basinghall Street, E.C. The lectures are at 6 p.m. Two have been already given, and the remaining two take place on Thursday and Friday.

The directors of the Royal Edinburgh Asylum have appointed Dr. George M. Robertson, M.B., C.M., F.R.C.P. (Edin.), to the post of Physician-Superintendent in succession to Dr. Clouston, retired. Dr. Robertson is at present Medical Superintendent of the Stirling District Asylum at Larbert.

It is announced that Mr. Andrew Carnegie has given half a million marks (£25,000) to the Robert Koch fund for the campaign against tuberculosis, and that so far the amount collected for carrying out research work in connection with the disease amounts to 800,000 marks.

Dr. P. A. Smith, a well-known Glasgow medical practitioner, was, on February 27th, entertained at a complimentary dinner in the Grosvenor Restaurant on the occasion of his silver jubilee. Rev. Canon M'Carthy, St. Andrew's, presided, and about 120 gentlemen were present.

An interesting presentation took place last week at Fraserburgh, when a motor-car was given to Dr. Trail by the townspeople in recognition of his services in the town, and more especially the good work he has done in attending to the poorer classes.

The Duke of Westminster has subscribed £200, Dr. Ludwig Mond £500, and Lord Sherborne £50, towards founding, in commemoration of a heroic Cheshire doctor, a "Dutton Memorial Chair," in tropical entomology and arachnology, in the Liverpool School of Tropical Medicine and the University of Liverpool.

The Attorney-General for Ireland has stated in Parliament that the Chief Secretary for Ireland proposes to introduce a "Tuberculosis Prevention" (Ireland) Bill, and that this will contain a clause providing for the compulsory notification of tuberculosis. The official supervision of dairies and of the sale of food will also be dealt with in this Bill, and in a new "Dairies Order" which the Local Government Board are about to issue.

A Clinical Lecture

ON

INDIGESTION IN CHILDREN.(a)

By G. F. STILL, M.A., M.D., F.R.C.P.,

Professor of Diseases of Children, King's College, London; Physician for Diseases of Children, King's College Hospital; Physician to Out-Patients, Hospital for Sick Children, Great Ormond Street.

Gentlemen,—Amongst the common disorders of childhood, I suppose there is none commoner than indigestion. And it appears under so many guises that it is little wonder if it is often mistaken for other conditions, and the child is dosed with this drug and that, when the one thing necessary is that the diet should be revised.

I do not propose to-day to consider the chemistry or physiology of indigestion, but simply to make some clinical remarks on indigestion as it is seen in children past the age of infancy.

The child, unlike the adult, is still in the active stage of construction, and should be steadily building. So that it requires an income sufficient not merely for the upkeep of what is already built, but for its extension. Anything which reduces its income interferes with the upkeep of the existing structure, for it is a fact that building continues even in spite of serious disease. Hence in the child any disorder which interferes with assimilation quickly tells upon the nutrition, and the child wastes. Such a disorder is indigestion. I lay stress upon the wasting because, not only does it arouse the mother's anxiety, perhaps more than anything else, but the doctor, too, is apt to be led astray by it, and to regard the case as one of tubercle. There is much to suggest tubercle in many of these cases, particularly if much mucus is being passed in the stools (the condition to which Eustace Smith gave the name mucous disease). In such cases often the skin becomes dry and harsh, as in tuberculosis, and there is also a hard, dry cough, which, with the wasting, makes the clinical picture very suggestive of tubercle. But the child rapidly improves under a proper diet.

Next to the wasting, I suppose no symptom distresses a mother more than the child's loss of appetite. Anorexia is often a most baffling symptom in childhood. A child of 3 or 4 will sit down to the table at meal-times and either refuse food altogether or take so little that the mother becomes alarmed. If the child is coaxed to eat, and persuaded to swallow against its will, retching follows, and it may even be sick.

There may be pain in the abdomen, sometimes in the epigastrium, sometimes in the middle part of the abdomen, sometimes over the lower part. The pain is at times so severe as to make the child cry out, though that is not usual. The abdomen is often enlarged in this condition, too, and the picture is not unlike that of tabes mesenterica, for which it is sometimes mistaken. Enlarged mesenteric glands should never be diagnosed unless they can be actually felt. In these cases of indigestion with recurring colicky pain, there may be little else to point to indigestion, and the case may therefore be puzzling. I saw, in consultation, a child, æt. 3½, with constant pain in the abdomen, which had been present six months. The child turned white sometimes with the pain, was nervous, could not sleep well, and during the two months before I saw it, had lost a pound in weight. I saw the child in one of the attacks; she leaned forward and pressed her hand over her abdomen in evident pain, but only for a moment. Two doctors had seen the case, and the various treatments had not done any good; neither did anything I suggested do good. At last the parents took the child to a surgeon, who advised an exploratory laparotomy. It was not, however, acquiesced in at the time, the parents preferring to postpone such a drastic measure. Then, as another chance of giving some relief, their own practitioner tried pancreatin, and thereupon the pain disappeared and the child became well, and remained so. It was a case in which there was difficulty in dealing with carbohydrate food, and the pancreatin happened to succeed. The pain in these cases is often associated with the passage of mucus in the stools, and one can understand why that should be so, when one has seen, at autopsies, especially on children who have suffered from worms, the thick, viscid mucus coating the intestines. The nervousness and inability to sleep well which the mother mentioned in the case just related is another common manifestation of indigestion. The mother's tale often is that "the child cries almost if you look at him." He lies awake for hours, or, after falling asleep, wakes frequently, and sleep is often disturbed by night terrors. Another symptom which makes the parents anxious is a sudden change of colour, the child going quite white. This is not imagination on the part of the mother—I have seen it happen. Such attacks have been spoken of as "vasomotor epilepsy." I confess I do not like the term; it seems to imply a connection with ordinary epilepsy, but, so far as I can judge from my own observation, no such relation exists. I used to think that consciousness was never lost in this condition, but I have found that rarely this does occur. The child turns white, and then falls down; the attacks appear to be syncopal in character rather than epileptic.

"My child is always tired. He never used to be so, but now, if he walks ever so little, he complains that he is so tired." Such a complaint, with the pain in the abdomen and the poor appetite, always suggests to me indigestion. The presence of indigestion is often suggested by a child's appearance; in some cases there is a blue puffiness under the eyes, especially at the outer part of the lower lid; in others there is what the mother calls "a dark ring round the eyes." Both these symptoms are often associated with mucous catarrh in the intestines. The puffiness is, of course, not pathognomonic of indigestion; it is seen with cyclical albuminuria in children, a condition, by-the-by, which is often accompanied by an unexplained colicky pain in the abdomen, which may possibly signify some mucous catarrh in the intestine here also.

The abdomen may be considerably enlarged in indigestion, and there is an enlargement of it which always suggests to me bread-and-butter feeding. The subject of it is usually a rather pale child, with a big, prominent abdomen, which lacks the resistance and doughy feeling of tuberculous peritonitis. This chronic enlargement of the abdomen is often found far beyond the usual age for rickets; it is not the rickety "pot-belly"; it is found especially in the child who does not care for milk, and will not eat meat, but is fond of bread and butter, off which he would willingly make all his meals. These cases are frequently sent to the hospital with a diagnosis of tuberculous peritonitis, whereas the effect of careful dieting, and perhaps of the administration of malt, speedily shows that the child is suffering from chronic indigestion.

Next, nausea and vomiting. I put them late in the list because they are not prominent in indigestion; but when they occur, they are apt to cause some anxiety. The association of occasional vomiting with wasting, perhaps with some headache and constipation, makes one think of the possibility of cerebral mischief. Usually the vomiting in indigestion is not continuous: it may occur only once or twice at intervals of several weeks. Sometimes there is not only vomiting, but a rise of temperature as well, the breath is offensive, the tongue furred, and the child seems ill. It is what the mother terms "a bilious attack." This usually means that there is an exacerbation of the digestive disturbance due to some more than usually indigestible food having been taken. The stools are commonly pale in these attacks, and, indeed, both in infancy and in later childhood whiteness or paleness of stools, which may remain for considerable periods, is a frequent manifestation of indigestion. On this account I am the less inclined to adopt the term acholia, the expressive term used by Dr. Cheadle as signifying a special disorder. Dr. Cheadle, in a very valuable paper on this subject, described a group of cases which are not very rare. A child of 3 or 4 years of age passes white stools, which are also greasy, as if they contained an excess of fat and were very deficient in bile. The child wastes gradually, but usually, after months of feebleness and ill-nutrition, slowly improves, and ultimately recovers. Very rarely do such cases end fatally. But similar stools are seen, sometimes for a day or two, sometimes for much longer, in the case of infants who have had for some time previously chronic indigestion, and it seems clear that the primary disorder in such cases is not deficiency of secretion of bile; the acholia is merely a secondary phenomenon.

(a) Delivered at the Hospital for Sick Children, Great Ormond Street, W.C.

The child with indigestion has also frequently offensive breath. Children are brought to the medical man sometimes only on this account. Of course, there are other causes for foul breath, such as bad teeth, and decomposing secretion in the crypts of enlarged tonsils; or the cause may be further removed and be due to bronchiectasis or ozæna. But the breath of chronic indigestion is heavy smelling, and not like these others, especially not like the sickening metallic odour of bronchiectasis or ozæna.

I have sometimes had children brought to me because of shortness of breath; at times the difficulty has amounted to "air-hunger." There may also be palpitation, so marked that the mother sometimes says she can feel the heart beating as the child sits on her lap leaning against her.

Another symptom which is very common in early childhood is lichen urticatus, and in some it persists until the sixth or seventh year. This, when present, is almost proof positive of there being something wrong with the feeding or the digestion.

The last symptom I shall refer to is one which is seldom mentioned in books, and that is dryness of hair, with loss of gloss. I have seen this only in two cases; in both there was chronic indigestion. With the improvement in the digestive condition the hair becomes normal.

Treatment.

With regard to the important matter of treatment, remember that faulty digestion does not always mean faulty diet. The teeth may be very defective, carious teeth in children being very common. Or many of the teeth may have been removed, and so mastication is apt to be very defective. Another cause for digestive disorder, apart from the diet itself, is bolting the food, not only because of bad teeth, but because, in this twentieth century rush, the child suffers as well as the adult from the all-pervading hurry which despatches even meals in the minimum possible time. This bad habit of hurried meals is often due to bad domestic arrangements; the meal times might be much better arranged. A child should not have to start for school about ten minutes after the beginning of a meal. Moreover, both mothers and nurses are apt to be impatient with a child over its food, and sometimes, to hasten proceedings, actually spoon the food into the child at such a pace that the child has barely time to take breath between the mouthfuls. I have seen this done, and the child vomit the whole of it immediately afterwards; and no wonder. Another small but important point is the midday sleep in relation to food. One sees children awakened from sleep to have their meal before they have had time to rouse themselves thoroughly. This, I always think, is bad for digestion. There should be an interval of twenty minutes or half an hour during which the child can run about between the midday sleep and the meal.

With regard to the food itself, there are two principles which I would emphasise: First, what is one person's meat is another person's poison—dogmatism and dietetics go ill together; the second principle is the one enunciated by Trousseau: never advise what a person should have until you know what he does have. Children, like adults, have their idiosyncrasies, and very marked ones, and the more experience I have the less I am inclined to pooh-pooh the mother's statement that the child cannot take this or that. For instance, I know no more valuable food for a child than eggs; neither do I know any in regard to which there is such marked idiosyncrasy. There are children who will vomit if you conceal the smallest amount of egg in their food. It is not a matter of dislike; the child seems to have a physiological inability to tolerate egg. Take another glaring example of idiosyncrasy to food: Porridge is taken well enough by many children, but with some it disturbs digestion badly, and, as a rare occurrence, it may have a remarkable effect, as the following instance may show:—I was told that a boy about 14 years of age could not take porridge, as it made his face swell. I was rather sceptical, and the boy was given some porridge one day in my presence. He had not finished the meal before one-half of his face began to swell, and about twenty minutes later it was so completely swelled up that he could scarcely see out of his eye. I have a photograph of this case of angio-neurotic œdema produced by porridge. It is, of course, a mere curiosity, but it illustrates my point that we must allow for idiosyncrasies in diet. There is need for much care in making inquiries as to what food the child is having. The mother may tell you the truth, and nothing but the truth, but nevertheless she often does not tell you the whole truth. Asked what the child has been having, she will sketch out an ideal diet, but she does not mention, unless carefully cross-examined, that the child has a raw apple before breakfast, a banana after breakfast; the bread eaten is brown bread; the child is fond of potatoes, and eats much more of that than of the chicken and gravy which the mother specially mentions. "Daddy's" sweets are not mentioned, nor the bits of rich cake coaxed out of mother when the child is allowed to be present at "afternoon tea." Get out all these details before you say what the child ought to have.

Turning now to the consideration of particular foods, let me say at once that the dyspepsia of childhood is generally a carbohydrate dyspepsia; hence it is that one of the foods which give rise to trouble is, as I have already mentioned, bread and butter. Many children do not care about meat and vegetables, but are much too fond of bread and butter, and it is a food which it is difficult to eliminate from the diet. The wise plan is to substitute proteid food as far as you can. Let the child have an egg with its tea; that will satisfy its hunger to some extent, and less bread and butter will be required. Breakfast should not, as it sometimes does, consist of porridge and bread and butter, but should include fish or egg or bacon fat. At tea I think it is well to allow a slice of plain Madeira cake and some plain biscuits or nursery biscuits, so as to reduce as far as possible the bread taken. I say Madeira cake rather than sponge cake, because I believe many of the shop-sold sponge cakes are less digestible than Madeira cake. A fruitful source of trouble with children is brown bread. It contains a large amount of unaltered husk, and so is very irritating. Where there is mucus in the stools, improvement will sometimes follow at once if you stop the brown bread which the child has been having. Any food which leaves a coarse residue is one which is tolerated badly by a child with any tendency to indigestion, and brown bread and porridge leave a very coarse residue in the stools. In stools from children fed on these foods the woody, indigestible material of which oatmeal and brown bread largely consist can be seen almost unaltered. Both brown bread and oatmeal have a laxative action, which depends entirely upon the mechanical irritation which they cause in the bowel. I often hear that bread has been forbidden, but that toast has been recommended as more digestible. There is some truth in this, but also a fallacy. If toast is given, it should be toasted through, so that it becomes brittle. But the child practically never gets it done in that way; it gets "pluffy" toast, or tough, greasy, buttered toast, which is anything but digestible.

At dinner potato is a source of much trouble. Children are very fond of it, and will often make their meal off it almost entirely. In the mucous disease which Dr. Eustace Smith so admirably described, potato is almost poison to the child, and the smallest amount of potato will re-start the symptoms just as the child is nearly well. If given at all, it should be well mashed, not simply with a fork, but with a potato-squeezer, or with a special potato-masher. I have seen, in children's stools, lumps of unaltered potato as large as the end of my little finger, looking as if the potato had come straight off the child's plate. What is to be given in the place of potato? You may give the child bread sauce. I do not think that is ideal, but it is better than potato, and most children like it very much.

I have spoken only of eatables so far. Let me remind you that the "drinkables" may be at fault. I need not say that tea is quite unsuitable for any child with digestive difficulty, and should never be given, except in weakest dilution, to the healthiest child; but I want to lay some stress upon the possibility of excessive milk drinking. I feel sure, from my own observation, that it is not very uncommon for a child to suffer with indigestion, with furred tongue, and offensive breath, because the mother insists in forcing upon the child perhaps more than a quart of milk a day, in addition to what is given in porridge or milk puddings. By all means let a child have as much milk as it can *easily* digest, but be careful not to pass this limit.

Lastly, let me say a few words with regard to drugs. Let me paraphrase Sir William Jenner's famous dictum and say, "When you see a child who is wasting, do not always think of cod-liver oil." There are many children who are losing flesh solely from indigestion, and the administration of cod-liver oil is more likely to retard digestion than to assist it. These are the cases in which malt is vastly superior to cod-liver oil, for, as I said, the indigestion of childhood is usually a carbohydrate dyspepsia, and the diastasic action of malt is therefore just what is required. I am fond of preparations in which some digestive ferment is also combined with the malt. There are many excellent preparations in the market, containing either pepsin or a pancreatic extract in combination with malt. Sometimes, especially when there is much gastric flatulence, a better result is obtained by giving alkalies with nux vomica; and where the appetite has become very poor without much flatulence, I think a mixture of dilute phosphoric acid with nux vomica is often better than an alkali.

Lastly, I would remind you that constipation—especially habitual constipation—is an extremely common association with chronic indigestion in children, and your treatment, if it is to be effectual in overcoming the digestive difficulty, must include the cure of the constipation.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Dr. H. Rabé, Professor in the Paris Faculty of Medicine. Subject: "Fœtid Bronchitis."*

ORIGINAL PAPERS.

TWO CLINICAL STUDIES OF CASES OF ENLARGEMENT OF THE SPLEEN

By W. B. WARRINGTON, M.D., F.R.C.P.Lond.,

Physician to the Northern Hospital; Lecturer and Examiner in Clinical Medicine in the University of Liverpool.

Synopsis.—I. Sailor, æt. 36. History of increasing asthenia, not exceeding two months. Admitted with profound anæmia and cachexia. Great enlargement of the spleen; slight enlargement of lymphatic glands. No leucocytosis; constant pyrexia; violent diarrhœa and delirium preceded death. *Diagnosis,* acute Hodgkin's disease

II. Great enlargement of the spleen in a pregnant woman, the subject of syphilis. Anæmia; two hemiplegic seizures. The post-mortem disclosed recent cerebral hæmorrhage, exuberant mitral vegetations, tuberculosis of one kidney, cystic degeneration of the other. The placenta showed evidence of syphilitic disease.

I. The ordinary form of Hodgkin's disease, which I may call, for purposes of contrast, chronic Hodgkin's disease, is well known. The clinical picture is as follows:—In more than half the instances the disease occurs in childhood. The constant feature is progressive enlargement of the lymphatic glands, and this almost always begins in the cervical region. Neighbouring glands become enlarged during this stage, which may last for months. The general condition is apparently normal. The second stage is marked by progressive asthenia, cachexia, and anæmia, and usually develops after one or more years. The anæmia is of the secondary type, and there is no increase in leucocytes. Irregular pyrexia is the rule. Enlargement of the spleen is nearly always present, and may be extreme. Pressure symptoms are frequent. The general duration of the disease is from one to four years. Its causation is unknown, and whether the disease is to be classified as a specific inflammation or a new growth has been much discussed. Similarly it has been denied and affirmed that any diagnostic histological structure existed in the glands.

The position held a few years ago is well shown by an anecdote related by Mr. Butlin during a discussion at the Royal Medico-Chirurgical Society, 1902.

A lady with enlarged glands in the neck was referred to him for an opinion—(1) as to whether an operation should be undertaken, (2) whether early marriage and residence in South Africa were permissible and desirable. Mr. Butlin at once recognised that the case was lymphadenoma, and both questions were, of course, answered in the negative. Shortly before the consultation a portion of a gland had been sent to the Clinical Research Society, and a report received to the effect "that the examiner could not make up his mind as to the structure, but that, although it was not typical of tubercle, he thought it was as much like tubercle as anything else."

A distinguished surgeon had also seen this section; his report was equally instructive: "I can't say that it is tubercle; but all I can say is, that if it is not tubercle, I don't know what it is."

A section was submitted to Dr. Kanthack, who, says Mr. Butlin, in about the time that one takes to recognise the structure of ordinary cancer, said:—"It has the characteristic structure of lymphadenoma." Mr. Butlin told the Royal Medico-Chirurgical Society that this was the first time he had heard that lymphadenoma had a characteristic structure. This statement of Kanthack's has since been fully confirmed by the writings of Andrews, Dorothy Reed (1902), Longcope (1903), and is accepted in the critical review of Max Borst (1905).

Longcope summarises as follows:—"The lesions in the lymph glands are especially characterised by the early increase in the lymphadenoid tissue, with later proliferation of endotheloid cells, formation of uninuclear and multinuclear giant cells, thickening of the reticulum, and final overgrowth of connective tissue. Eosinophile cells, though not specific, are frequently found in great abundance. The tubercle bacillus plays no part in the production of the lesions."

Thus, after a lapse of seventy-five years, Hodgkin's statement in his original description, 1832, that "any scrofulous condition is regarded as an accidental concomitant to the idiopathic interstitial enlargement of the absorbed gland tissue throughout the body" is confirmed.

Ordinary Hodgkin's disease itself is not a common disease, and still more infrequent is the group of cases characterised by enlargement of glands, a rapid course terminating fatally in a few weeks or months with fever, profound anæmia, hæmorrhages, coma and delirium. The glands enlarged may be the superficial glands or the intrathoracic or abdominal glands. If the superficial glands are enlarged, acute tuberculous or primary malignant sarcoma have to be considered; whilst, if abdominal symptoms predominate, the disease may simulate typhoid fever, acute tuberculous peritonitis, or forms of septicæmia with purpura. When the glands of the mediastinum are affected, the physical signs may resemble mediastinal tumour; but I think it is proper to adopt the position taken by Dr. Lindsay Steven, and to separate clinically, at least, primary sarcoma of the lymph glands of the mediastinum which may give true metastases or enlargement of superficial glands by pressure on the right or left lymphatic duct from a generalised morbid enlargement which incidentally may affect the glands in the mediastinum. The latter condition may best be called acute Hodgkin's disease, and clinically seems to be distinguished from primary sarcoma by the more rapid course, with marked constitutional symptoms, and a less degree of severity of pressure symptoms, which are usually the cause of death in the primary mediastinal tumours.

I may now relate the history of my patient who suffered from what I prefer to call acute Hodgkin's disease in preference to such names as malignant lymphoma, or lymphosarcoma. The clinical summary is:—Sailor, æt. 36. History of increasing asthenia, not exceeding two months. Admitted with profound anæmia and cachexia. There was an enlarged spleen and *slight* enlargement of the inguinal and axillary glands. Violent diarrhœa, delirium, and constant pyrexia were marked symptoms, and death occurred in a month after admission.

In forming the diagnosis, malignant malaria, typhoid fever, and pernicious anæmia have to be considered.

F. K., a sailor, æt. 36, employed in the South American trade, and has had many attacks of malaria. He was well up to Christmas of 1906, but was unable to return to sea on account of general weakness.

On admission the patient was obviously very ill. His temperature was 103°; pulse 140 and of low tension; the tongue was thickly furred and sordes were present on the lips.

The cardiac apex was diffuse and felt just outside the nipple line. The cardiac sounds feeble, with a soft systolic murmur over the pulmonary area. No lesion was found in the lungs. The urine contained a trace of albumin.

He was found to have marked anæmia, and the spleen and many lymphatic glands were enlarged, though only slightly, none being larger than a hazel nut.

The examination of the blood gave the following results:—

Erythrocytes = 1,750,000.
Hæmoglobin = 22 per cent.
Leucocytes = 6,400.

The lymphocytes were relatively markedly increased, being nearly as numerous as the neutrophile cells. The red cells were normal in appearance, with the exception of the presence of a few normoblasts. There were no malarial parasites, and no ova were detected. The serum reaction to *B. typhosus* was negative.

The glands of both axillæ and inguinal regions were moderately enlarged. They were discrete and elastic, and not larger than a hazel nut. In the cervical region there was also some enlargement of glands, but to a much smaller degree. There were no clinical indications of enlarged glands in the thorax or abdomen.

The spleen was markedly enlarged, reaching to within two inches of the level of the umbilicus. The liver was of normal size, and no lesion was found in the lungs.

Progress.—The anæmia increased. On March 15th, the erythrocytes numbered only 1,008,000, and the hæmoglobin index had fallen to 17 per cent. A large number of normoblasts and poikilocytes had appeared. No noticeable alteration in the white cells.

The constitutional symptoms increased in gravity. On the night of March 3rd wild and maniacal delirium set in, and though at times the patient was rational, the delirium was a constant feature until his death.

Irregular fever, violent diarrhœa, and the "typhoid" state continued until the end, which occurred one month after admission.

The autopsy showed the heart muscle to be pale and soft, the cavities dilated; the valves were normal. Beyond slight degeneration of the coronary arteries, there was no atheroma. The lungs, stomach, and bowels were normal. The liver weighed 3 lbs. 11 ozs., and showed fatty changes in the cells. The spleen weighed 2 lbs. 2 ozs.; the organ was lobulated and of a soft consistence. It contained numerous white, hardish nodules, the size of hazel nuts, which were visible both superficially and found in its substance.

Enlarged glands were found in the axillary and inguinal regions, and larger masses in the abdomen, especially situated on the posterior wall. The mediastinal glands were not enlarged.

The bone marrow removed from the femur shaft was redder than normal.

Microscopical examination showed in the glands the characteristic structure of Hodgkin's disease: 1. The disappearance of the normal contrast between medulla and cortex. 2. The increase of the fibrous network and diminution of the lymphoid cells. 3. Presence of numerous large, multinuclear endothelial cells, the so-called "lymphadenoma" cells. I was unable to find eosinophilous cells.

The enlargement of the spleen was found to be due to increase in the connective tissue stroma, great venous congestion, and the presence of nodules, which were seen to have the same structure as the glands, together with much necrobiosis in places.

I cannot now discuss the numerous observations on the relationship between the various kinds of glandular enlargement. Orth remarks, "There are few regions of pathological anatomy where there is such darkness, even error, or where the gaps in our knowledge are so wide."

Certain facts seem clear:—

1. In ordinary Hodgkin's disease the glandular enlargements have a specific or recognisable structure.
2. Tuberculosis, if present, is merely an added lesion.
3. I have shown in my acute case that the same characteristic structure was present.
4. Many observations show that in acute conditions the blood may rapidly alter, a great increase of lymphocytes occurring, so that the disease may clinically be indistinguishable from lymphatic leukæmia; but that
5. Further observation is required on the structure of the glands in such cases.

The section of a gland I show from a fatal case of lymphatic leukæmia has an entirely different structure from that of the present case.

It has been urged in an interesting paper by Dreschfeld on acute Hodgkin's disease that the changes in the glands are merely modifications of the same process and to be explained by the rate of growth.

J. H. Abram makes some precise statements as to the clinical differentiation between lymphadenoma, lymphosarcoma, and lymphatic leukæmia, which undoubtedly correspond to clinical findings.

Türk gives a classification depending on the condition of the blood and the benign or malignant nature of the growths, *i.e.* their proliferating and destructive characteristics, and states that all the clinical conditions in this classification pass over into each other.

A. Chronic benign growth.
    1. Alymphemic (chronic Hodgkin's).
    2. Sublymphemic (pseudoleukæmia, *i.e.*, a slight absolute lymphocytosis.
    3. Lymphemic (chronic lymphatic leukæmia).
B. Acute growth:
    Partly benign, partly malignant, including acute lymphatic leukæmia and chloroma.
C. Chronic malignant growth without blood changes, including general lymphosarcoma or local lymphosarcoma.

I think there is little doubt as to the accuracy of the clinical pictures of these varying conditions, but submit that, in view of the very demonstrative findings of Reid, Longcope, and others, and which, judging from the literature, are hardly yet recognised, the anatomy of the acute cases should once more be reinvestigated.

II. N. C., a married woman, æt. 28, was sent into hospital by Dr. White, of Northwich, on March 26th, 1907, on account of an abdominal swelling. She had been married six years, and of three pregnancies, one resulted in a miscarriage, the second a still-born child, and at the third, eighteen months ago, she gave birth to a child who lived only four days. Four years ago she had a sudden left hemiplegia, without loss of consciousness; the weakness soon disappeared. Since Christmas an abdominal swelling had been noticed, and there had been amenorrhœa for eight months. Five weeks ago the patient was awakened by severe pain in the left upper limb, which in the morning was noticed to be greatly swollen.

On admission the patient was very anæmic, with marked œdema of the left upper and lower limbs, and to a less extent of the right lower limb. There was œdema also of the trunk, almost entirely limited to the left side, and the superficial veins over the left half of the thorax were dilated.

In the abdomen there were two large, obviously independent tumours. One of these, a hard, smooth mass, coming from under the left costal margin, reached inwards as far as the umbilicus and downwards into the left iliac fossa, was diagnosed as the spleen. The other, a softer tumour springing from the pelvis and displaced by the spleen to the right, was considered by Dr. Willett, who kindly saw the case, as a pregnant uterus. The outlines of the fœtus could be palpated, but no evidence of life was detected. In both axillæ the glands were slightly enlarged, but the neck and inguinal regions were free. Examination of the blood showed the number of erythrocytes to be 2,154,000; white cells, 7,100; hæmoglobin = 40 per cent. The percentages of the varieties of white cells were practically normal. There were no myelocytes, but a few normoblasts were seen.

The heart was normal in size, but the first sound at the apex replaced by a long systolic bruit conducted to the axilla. Respiratory system normal. The urine contained a small amount of pus.

Progress of the Illness.—The dyspnœa on any exertion troubled the patient a good deal, and later examination of the blood showed that the anæmia was increasing; the erythrocytes fell to 1,480,000 per cb. mm., and the percentage of hæmoglobin to 17 per cent., whilst the number of white cells equalled only 2,187 per cb. mm. The blood cells preserved their normal appearance.

On April 22nd, a dead child, weighing 2½ lbs., of about seven months' intra-uterine age, was born. Labour lasted nine hours, and was attended with but little hæmorrhage and discomfort to the patient. Five days later the patient became unconscious; a series of left-sided convulsions occurred, followed by hemiplegia. The patient never regained consciousness; the temperature rapidly rose to 105°, and death occurred on May 1st.

Autopsy—Brain.—At the junction of right Rolandic and Sylvian fissure a small cyst was found, containing hæmorrhagic, amber-coloured fluid. The brain tissue immediately beneath the cyst was red and softened. The arteries were not degenerated, and no evidence of a thrombus or embolus was seen. This lesion was no doubt recent, and the cause of the convulsions and hemiplegia, which appeared shortly before death. An anatomical basis for the earlier hemiplegia could not be found; an obsolete, probably tuberculous lesion was present in the apex of the right lung.

The bronchial and axillary glands were distinctly enlarged. The heart showed some slight enlargement; the muscle was soft and friable. Tricuspid valve dilated but normal; aortic and pulmonary orifices normal. The mitral orifice was dilated, and on both cusps of the valve there were copious, large, mostly recent vegetations.

No ascitic fluid in the abdomen. The spleen was enormously enlarged, and weighed 58 ozs. There was marked perisplenitis, the capsule being in some places 1-16th inch in thickness. There were depressed cicatrices on the surface, and two large infarcts, one reddish brown, the other hard, white, and triangular, with its base at the surface. The liver was slightly enlarged, pale, and soft. The left kidney weighed 5 ozs.; its cortical part was replaced by numerous cysts, varying in size from a pin's head to a cherry; they contained dark brown gelatinous fluid. The medulla was nearly free. The right kidney weighed 6½ ozs., and contained a typical caseous, tuberculous mass. The rest of its substance was fairly healthy.

Putting together the clinical and pathological findings, I think we may summarise the case as follows:—

A young woman suffering from acquired syphilis developed hemiplegia, probably due to endarteritis—rapid improvement and fair health for three years. Pregnancy then occurred, and after some months, in addition to the uterine growth, a very large spleen with marked anæmia was discovered. Thrombosis of the veins of the upper limb probably accounts for a sudden painful seizure and rapid œdema of the upper limb. A systolic cardiac murmur was found to be due to large, probably recent vegetations, on the mitral valve; pyuria and albuminuria due to a tuberculous lesion of one kidney and a cystic degeneration of the other. Death occurred from a second cerebral seizure, probably hæmorrhagic.

During life the pathological interpretation of the clinical picture was difficult. An explanation had to be found for the very large spleen. Leucocythæmia, Hodgkin's disease, malaria, and primary splenomegaly are diseases generally credited as associated with the largest spleen. The first three could definitely be excluded. This left for consideration primary splenomegaly, the high probability of acquired syphilis, and the suspicion that the cardiac bruit might be of organic origin. In spite of the copious literature now existing on primary splenomegaly, it seems to me that the diagnosis must often be made more by exclusion than from the presence of any certain and precise symptoms.

Critical remarks would hardly be in place with my case as a test. A few observations may, however, be made.

The conception of primary splenomegaly seems to have evolved out of observations on Hodgkin's disease, so that a splenic form of this disease or of pseudoleukæmia, as it is often called, became recognised. In 1883, Banti described a series of three cases characterised by a splenic tumefaction independent of any preceding morbid condition, with grave disturbances in the organic functions, irregular fever, and hæmorrhages, and terminating fatally. Sippey, in 1899, recognised a syndrome group characterised by enlargement of the spleen, which preceded or developed with an anæmia which might be very severe; a second stage of gastro-intestinal disturbance; and general asthenia and fatal termination in cachexia. Osler, in 1902, analysed a large number of cases occurring in the practice of American physicians. Rolleston soon after discussed the question, and Taylor, in the Lumleian lectures for 1904, generally accepted these conclusions, and sums up as the criteria of splenic anæmia or primary splenomegaly:—

(1) Enlargement of spleen; (2) absence of glandular enlargements; (3) anæmia of chlorotic type; (4) leucohemia; (5) long course; (6) tendency to hæmorrhage, especially from the gastric mucous membrane; (7) pigmentation of the skin and a termination in secondary enlargement of the liver, with ascites and jaundice, these added symptoms constituting what is called Banti's disease.

This precise definition no doubt covers the natural history of many cases. It may be very difficult to classify individual cases.

In my cases the pathological findings show that no less than three sources of toxæmia were present—viz., syphilis, tubercle, and recent virulent endocarditis, and these may have been sufficient to account for both the anæmia and large spleen.

The spleen most readily reacts to systemic or portal infection. Its swelling is due to congestion, accumulation of non-granular phagocytes, and of elements in the process of destruction, bacteria, neutrophile leucocytes, red corpuuscles and degenerating cells.

In looking over the records of cases of large spleen, I was surprised to find how very large the spleen in ulcerative endocarditis may be. Taylor mentions several in which the weight was between 35 and 43 oz.

The largest weight mentioned I find was 128 oz., and this was probably due to cardiac stagnation with malaria. Lastly, as showing the complex nature of some instances of splenomegaly, I may recall Coupland's case published in 1896—a woman with an enormous spleen and severe anæmia. The spleen was removed, and the patient rapidly regained health. Some years later hæmatemesis and ascites appeared, from which the patient died. A typical syphilitic liver was found at the autopsy.

This case seemed to present the combination of primary splenomegaly with syphilis, perhaps as an independent lesion.

HÆMANGIECTATIC HYPERTROPHIES OF THE FOOT AND LOWER EXTREMITY, CONGENITAL OR ACQUIRED.

By F. PARKES WEBER, M.D., F.R.C.P.,

Physician to the German Hospital, London, and the Mount Vernon Hospital, Hampstead.

Some time ago I drew attention to a group of rare cases (*a*) seen in children, in which hypertrophy of one limb is found to be associated with tumour-like overgrowth in the corresponding portion of the vascular system. It seems as if the hypertrophy, affecting the soft tissues, and usually the bones as well, depended in these cases to some extent at least on excessive vascularity of the affected parts caused by the overgrowth of blood-vessels. The abnormalities in question are congenital, or at all events are noticed soon after birth, though they may be "developmental," and become more obvious and remarkable later on as the general development of the child progresses. The vascular overgrowth differs in amount and kind in different cases, and is not rarely accompanied by quite obvious tumour-formation in the shape of some kind of superficial hæmangioma (occasionally lymphangioma). There may be, for instance, a diffuse cutaneous capillary (simple) nævus of the "port wine stain" kind (nævus flammeus), or there may be hæmangiomatous nodules (cavernous angiomata), or, more rarely, a lymphangiomatous growth of the skin (a lymphangioma may, however, be dark red in colour from hæmorrhage into some of the superficial lymph-vesicles). Sometimes the main arteries of the part can be felt greatly enlarged, and one or more veins may be dilated; in fact the affected limb may be the site of a so-called congenital or "early developmental" varicose vein. (*b*)

From what is known as congenital (or early developmental) "trophœdema" (*c*) or "trophic œdema" of extremities, which tends to run in families, the condition now under consideration may be distinguished: (1) by the associated vascular abnormalities, and (2) by there being usually an actual increase in the length of the bones of the affected limbs, which is generally not noticeable in trophœdema. (*a*)

From what may be termed the real or *typical* cases of local "gigantism," the condition under consideration may be distinguished (1) by the hypertrophy being not nearly so great as in characteristic examples of giant fingers, giant toes, giant feet, etc., and (2) by there being usually no disproportionately excessive vascular development in *typical* local gigantism. Confusion is hardly possible with cases of so-called "elephantiasis," due to chronic or recurrent lymphangitis and lymphatic obstruction.

Cases of congenital and early developmental hæmangiectatic hypertrophy are certainly rare, but a similar form of hypertrophy acquired in later life is rarer still. I have recently met with a case of hæmangiectatic hypertrophy of the left foot arising in a young adult. (*b*) The patient is a motor driver, æt. 19, whose left foot is decidedly larger than his right foot, and of a red, or bluish-red, colour as if turgid with blood. The skin over part of the foot, especially over the dorsum, is closely studded with small projecting bluish venous loops (varices), and so also, though to a lesser degree, is the skin over the knee-cap of the same extremity. The calf-muscles and other muscles of the leg are about equally developed on the two sides, but there is considerable wasting of the left thigh and buttock, and there is ankylosis of the left hip-joint. The two lower extremities are about equal in length. The knee-jerks and plantar reflexes are natural, and there is no ankle-clonus on either side. The pulsation in the dorsalis pedis artery is well felt in both feet. There is no anæsthesia to touch, pain, heat, or cold, and the reactions of the muscles to galvanism are normal. In the dorsal region of the spinal column there is considerable kyphosis. No evidence of any disease can be discovered in the thoracic or abdominal viscera or elsewhere in the body. Dr. Archibald D. Reid has kindly taken Röntgen photographs of the feet and hip-joints. They show that the hypertrophy of the left foot is practically confined to the soft parts, and likewise that there is bony ankylosis of the left hip-joint (of doubtful origin).

The history is that about two years ago the patient complained of pain in the back of the left thigh. He was at first treated for sciatica, and was afterwards supposed to have hip disease, and wore a Thomas's splint for 18 months. The hæmangiectatic hypertrophy of the left foot and the wasting of the thigh muscles, etc., have developed during the last two years, but apparently the dorsal kyphosis existed previously, though it seems to have increased during the last two years. There has been no pain in connection with the changes in the lower extremity excepting the pain (previously mentioned) at the back of the thigh about two years ago. In this case I think that the condition of the foot (increase in size, engorgement with blood, and superficial hæmangiectases is of vasomotor origin (due to vaso-constrictor paralysis?) are possibly connected with some organic change in the spinal cord.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Retro-Pharyngeal Abscess. — Mr. Willmott Evans operated on a child, æt. 16 months, who had been admitted for difficulty of swallowing. For three

---

(*a*) "Angioma-Formation in Connection with Hypertrophy of Limbs," *British Journal of Dermatology*, July, 1907. I originally included certain cases of hemi-hypertrophy.

(*b*) The occasional occurrence of such congenital or "early developmental" varicose veins affords strong support to the view that varicose veins are venous overgrowths allied to venous angiomata. On this subject see A. Pearce Gould's "Lettsomian Lectures" in the *Med. Soc. Trans.*, 1902, vol. xxv., p. 132; also W. Thorburn's remarks on "Developmental Varix," *Brit. Med. Journ.*, November 17th, 1900, p. 1,421, and Sir W. H. Bennett's remarks on "Congenital Varix," *Lancet*, November 22nd, 1902, p. 1,374. In fact, although intravenous pressure and inflammatory conditions are probably the usual exciting causes of the ordinary varicose veins of the lower extremities, a peculiar, sometimes hereditary, tendency towards varicose veins must be admitted in many cases. In regard to the analogous relationship which the ordinary hair-like telangiectases of the skin bear to cutaneous angiomata, see "A Note on Cutaneous Telangiectases and their Etiology—Comparison with the Etiology of Hæmorrhoids and Ordinary Varicose Veins," by F. Parkes Weber, *Edinburgh Medical Journal*, April, 1904, p. 346.

Meige, Société de Neurologie, Paris, November 7th, 1901; Debove *Presse Médicale*, Paris, May 28th, 1902; H. D. Rolleston, *Lancet*, September 20th, 1902, p. 805; O. Grünbaum, *Reports of the Society for the Study of Disease in Children*, 1905, vol. v., p. 4; Zuber, *Société de Pédiatrie*, Paris, June 19th, 1906; Senlecq, *Société d'Obstetrique*, Paris, December 10th, 1906; and Guinon, *Ibid.*, March 11th, 1907.

(*a*) When hæmangiectatic hypertrophy affects older persons the bones probably do not take part in the hypertrophy, and the increase in size is probably confined to the soft parts (see later on), if it occurs at al..

(*b*) I showed the case at the Dermatological Section of the Royal Society of Medicine, London, on February 20th, 1908.

months before admission the little boy had had some difficulty of swallowing, and the mother had noticed a swelling on the left side of the neck, extending forwards as far as the submaxillary region. Occasionally there was dyspnœa, and once or twice the child had nearly choked. Fomentations had been ordered, and the swelling slowly decreased in size. On admission it was seen that the child was very thin, this being probably due to the fact that it had been able to take very little nourishment in the last three months during which time it had been hand-fed. On examination there was a little fulness on the left side of the neck, but nothing like the swelling described by the mother; at the back of the pharynx could be seen and felt a soft, fluctuating swelling extending upwards to about the level of the floor of the nose and downwards for nearly three inches, but the lower limit could not be well defined as the finger could not reach so far. A diagnosis of retro-pharyngeal abscess was made, and it was decided to drain it. A vertical incision was made along the posterior border of the left sterno-mastoid, beginning about half an inch below the mastoid process, and extending downwards for about an inch and a half. As soon as the deep cervical fascia had been cut through the deeper structures were carefully dissected, partly with a knife and partly with a steel director. The sterno-mastoid was retracted inwards, and the dissection was carried on towards the middle line of the body. The transverse processes of two or three of the cervical vertebræ were defined, and the director was passed inwards immediately in front of them. Thin, yellowish inoffensive pus was readily found, and about an ounce and a half was evacuated; the abscess cavity was washed with normal saline solution until the fluid returned clear. A small drainage tube was inserted. Four stitches were employed to close the upper and lower parts of the wound, and sal alembroth dressings were applied. Mr. Evans said that an abscess behind the pharynx may be due to one of three causes: the most severe was that associated with tuberculous caries of the cervical spine; it may also follow the passage of a sharp septic body such as a spicula of food or a bone through the posterior pharyngeal wall. The third cause was, however, the most common; the disease occurring in small children associated with suppuration arising in the retro-pharyngeal lymphatic glands, and caused by the absorption of organisms from some septic focus in the mouth or throat. Whatever may be the origin of a retro-pharyngeal abscess it was essential it should be opened early, for if not irremediable trouble may result in several ways. By pressing forward the posterior wall of the pharynx it interfered with swallowing and with breathing, and in this way may lead to a fatal result, or the abscess may burst through the pharynx, and the pus flowing into the pharynx may cause death; equally serious were the consequences of pus tracking downwards behind the pharynx and œsophagus, in this way it reaches the posterior mediastinum, and spreads widely in the loose connective tissue. There were, he pointed out, two methods of draining a retro-pharyngeal abscess: the older was to make an opening into the swelling as it presents at the back of the pharynx, a straight bistoury guarded by strapping except at the point being employed. The objections to this plan are twofold: in the first place, if much pus be present, the sudden outflow of it may conceivably prove fatal by its entering the larynx; there was, however, the additional danger that the opening through which the abscess has been drained might prove a point of entrance for other micro-organisms, and thus a very septic condition may be set up behind the pharynx, worse, even, than the abscess which has been incised. Far better was it, he thought, to employ the more modern method of draining the abscess through an opening made through the outside of the neck. It was true the operation required more skill and knowledge of anatomy, but the results were far better than those following the pharyngeal incision, and the risks were much less. It was important to remember the situation of the abscess; it lies in the cellular tissue, bounded behind by the layer of fascia covering the prevertebral muscles, and in front by the posterior wall of the pharynx. To reach this space most conveniently, it is necessary to pass behind the carotid sheath; the incision, therefore, is made at the posterior border of the sterno-mastoid, and when that muscle is retracted towards the middle line, the carotid vessels will be brought forward also. After this the surest guide to the retropharyngeal space is to be found in the anterior tubercles of the transverse processes of the cervical vertebræ, to which are attached tendinous slips of the Longus colli and Rectus capitis anticus major muscles. One structure should be carefully avoided in the preliminary incision behind the sterno-mastoid—viz., the spinal accessory nerve. It was important that the cavity should be drained for a week or two, so that it may close from the bottom. With regard to the dressings to be employed, he held that when an operation case was aseptic, it was desirable to use simply aseptic dressings, but when micro-organisms were already present, as in opening an abscess, it was better both for the patient himself and for the other cases in the ward that antiseptic dressings should be employed.

It was noticed soon after the operation that the breathing had improved, and the child was able to take his milk much better. On the third day after the operation, from no apparent cause, the temperature rose to 101°, but it fell on the same evening, and did not rise again above normal. The stitches were removed on the sixth day, and the tube was withdrawn fourteen days after the operation. On examination of the pus, no tubercle bacilli were found. The patient left the hospital on the sixteenth day with a minute sinus and perfectly well in himself.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, FEBRUARY 7TH, 1908.

The President, E. H. TWEEDY, F.R.C.P.I., in the Chair.

OVUM FROM HORN OF BICORNUTE UTERUS.

THE PRESIDENT exhibited an ovum from the horn of a bicornute uterus. It was, he said, a very perfect ovum, though now shrivelled in spirit. The woman, who had borne three or four children, had had persistent hæmorrhage since January. He made a tentative diagnosis of tubal pregnancy. He operated the following day, and, to his surprise, found a small uterus, with the tumour growing out from the side of it. When he split the tumour in the direction of the tube, the ovum came out, and it then appeared that he was dealing with a two-horned uterus. In thinking the case over, he was convinced that the woman would have carried her child to full term. She had had two miscarriages and three children, and they had all, he believed, developed in that horn. The whole question of operation in a two-horned uterus was in an unsettled state. They were led to suppose that even if they diagnosed a pregnancy in a two-horned uterus, they should treat it as though it were a tubal pregnancy; but there was no doubt that there were many women who bore children in the presence of this abnormality. The size of the tumour might have led him to a correct diagnosis; it had grown enormously in the ten days between his examination and the operation, yet it had not burst. He had never seen a tubal pregnancy so large without rupture taking place, a fact which might have put him on the way to a correct diagnosis.

Dr. **HOLMES** asked if anything had come away from the uterus since the operation, as it had recently been stated that false decidua would give rise to trouble in the other horn?

Dr. **NEILL** asked if there had been any trouble with the former deliveries?

The **PRESIDENT**, in reply, said that if they could diagnose that the pregnancy had taken place in the well-developed horn, everyone would agree that it should be left; but the difficulty of diagnosing between the horns was very great. In the case before them the undeveloped horn was as large as a normal uterus. Nothing had come from the uterus since; and, so far as he knew, all the other full term deliveries were normal and easy.

A MODIFICATION OF NEVILLE'S FORCEPS.

Sir A. **MACAN** said it was not without a good deal of thought that he had ventured to make a modification on Dr. Neville's forceps, on which he had a stop put, so that, by making a slight movement of the axis-traction handle, he could tell at once, without looking, that the pointer was in the right direction. He described in detail, with specimens, the development in the shape and mechanism of forceps, from the straight to the extra-curved German form.

Dr. **FITZGIBBON** said that being able to utilise one's ears was an advantage, though he did not see the necessity of watching the perineum at the time the axis-traction was in use.

Dr. **HOLMES** thought the addition of the small check was of great use in allowing the eyes to be taken off the forceps and the whole attention to be given to the perineum.

Dr. **SPENCER SHEILL** said that although the Scottish forceps had a device by which a click would tell when they were pulling in the axis of the pelvis, it had the disadvantage of possibly nipping the vaginal mucous membrane; but the one shown had the advantage of the Simpson forceps without its disadvantages.

A VESICULAR MOLE.

Dr. **SPENCER SHEILL** exhibited a vesicular mole. He was, he said, somewhat disappointed, as he had entered it in the hope of being able to exhibit it as a case of a twin mole, one embryo having been, so to speak, converted into the mole, and the other fairly normally developed. The patient had a marked history of twins in her own and her mother's family. She had aborted four times, one being a twin abortion. Afterwards, in a twin conception, she aborted one, and he subsequently delivered her of a full term child. The specimen shown was the next pregnancy. There was a marked amount of fibrous degeneration and a great deal of fibrous tissue and thickening, but there was no syphilitic history to account for it. The pathological report which had been kindly made by Dr. Rowlette, and which he read, not only disappointed his hope of being able to exhibit a specimen of a condition which had only been reported a couple or three times, but also drove him to the opinion that it was a case of what he might call mixed carneous and hydatidiform mole.

The **PRESIDENT** said he had never seen a vesicular mole together with any portion of a formed fœtus, as in Dr. Sheill's specimen. He did not, however, agree that it was a carneous mole. He would like to know if the specimen came away spontaneously or if it had been delivered manually.

Dr. **SHEILL**, in reply, said the specimen was delivered by the natural contraction of the uterus. His opinion as to the nature of the mole was based on the naked eye appearance, and on considering again the pathological report, he bowed to the Pathologist's opinion that it was not a carneous mole.

THE OPERATIVE TREATMENT OF PUERPERAL INFECTION.

Sir A. **MACAN** read a paper on the above subject, the discussion of which was, on the motion of Dr. Holmes, seconded by Dr. Ashe, postponed until the next meeting.

A paper entitled (*a*) "Twin Abortion with Double Placenta Prævia and a remarkable condition of the Cervix Uteri; (*b*) Labour Shock," by Professor R. J. Kinkead, of Galway, was read by Dr. G. FitzGibbon, the Acting Secretary.

Sir A. **MACAN** and the **PRESIDENT** expressed the thanks of the Section to Professor Kinkead, and the hope that other members in the country would contribute similar valuable papers.

The following card speciments were shown:—Dr. Tweedy—(*a*) Dermoid cyst of ovary containing teeth; (*b*) ovarian cyst specimens (2); (*c*) fibroids of uterus (3), one showing cystic degeneration; (*d*) abscess of ovary.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, FEBRUARY 21ST, 1908.

The President, Dr. **WALKER DOWNIE**, in the Chair.

Dr. **J. CRAWFORD RENTON** showed a lad who had his elbow-joint excised, and showed the bony parts removed from this and other three cases of the same kind. He made remarks on the results following excision of the elbow-joint when the ends of all the bones entering into the formation of the joint are removed. Attention was called to the large space left without bone, and special stress was laid upon the amount of usefulness regained by the limb some time after such extensive operations. In about two years there is not much deformity, and the muscles get so strong that the usual occupations can generally be engaged in. This was shown in the case brought forward, and in photographs from other cases. Dr. Renton then showed two ruptured spleens that had been removed by operation, and gave a short account of the cases. The rupture in both cases was due to injury, and in one of the cases resulted fatally. The other case was a lad, 19 years of age. An hour after injury he was found suffering from internal hæmorrhage. On opening the abdomen the spleen was found to be ruptured, and was extirpated. A week later the right pleura filled with fluid, and 60 oz. of blood-stained but sterile fluid was drawn off. A week later he had to be treated for empyema of the same side, and later still pneumonia supervened. The patient, however, made a good recovery. During the first three weeks after operation there was a gradual diminution in the proportion of hæmoglobin, lymphocytes and phagocytes in the blood. After that time the blood began to regain its usual proportions of these, and on the sixty-third day it was quite normal again. Dr. Renton then showed a number of calculi he had taken from the kidney, ureter and bladder, and exhibited Cole's apparatus for allowing the escape of urine after suprapubic cystotomy. In the case where several large calculi were removed from the kidney, the patient was suffering from pulmonary catarrh. Administration of a general anæsthetic was not considered safe, and stovaine was injected into the spine. There was absolutely no pain, and Dr. Renton expressed great satisfaction with the use of this anæsthetic.

Dr. **RENTON** also showed specimens of four ruptured vermiform appendices, and made a few remarks on the cases. These illustrated the importance of operating at the earliest possible moment when the appendix is diseased, an opinion expressed by him six years ago, and which he has had every reason to adhere to up till the present time. In conclusion, Dr. Renton gave notes of four cases of intussusception, and then made some remarks on Mayo's method of gastro-enterostomy based on his experience of 15 cases. In recommending this method, he referred to its being the application of the posterior portion of the stomach to the jejunum, this being the normal anatomical relation of these parts. He referred to a case pictured in an old pathology book in which Nature had accomplished the same result as the operation by adhesion of the stomach and jejunum at the seat of a gastric ulcer on the posterior wall, and perforation through this into the jejunum.

Dr. **WILLIAM MCLENNAN** related the clinical history of an unusual case of mediastinal tumour, and illustrated it by lantern slides. The patient was a woman, æt. 28. Twelve years ago she had a swelling of the neck, and for this an operation was performed. This was the removal of an encapsulated tumour from the thyroid gland. No microscopic examination was made of this, and nothing further noted till recently. The woman was admitted to the infirmary with a swelling at the root of the neck. Six weeks previously she was confined, and after this event the swelling appeared and grew rapidly. It formed a large mass behind the sternum and at the root of the neck, setting up pressure symptoms which, after ten weeks' illness, ended in death from asphyxia. For some time before death the temperature was observed to be above normal, fluctuating between 100° and 101°. Dr. William McLennan considers this a fairly common occurrence in malignant tumours, and was often a help in making the diagnosis. Sections of this tumour showed it to be a double tumour consisting of a carcinoma of thyroid gland tissue and a much larger amount of sarcomatous tissue, made up both of round and spindle cells. Only the lymphatic glands that receive lymph from the region of the tumour were affected with secondary deposits of carcinoma; but nearly all the organs of the body had secondary deposits of sarcoma. The interest of this case rested upon the presence and extirpation of an innocent thyroid tumour at the age of 15, the growth of a malignant thyroid tumour, and the development from this of a sarcomatous growth which extended rapidly and disseminated itself throughout the body, leading to death.

Dr. **JOHN SHAW DUNN** showed lantern slides made from a case of accessory thyroid tumour of the neck. Dr. Alex. McLennan gave a short report of this case, and showed photographs of the patient taken before operation. The sections of the tumour showed thyroid tissue with fibrous septa, and from these septa numerous papillomatous processes.

Dr. **ALEX. MACLENNAN** also gave a lantern demonstration of the changes that occur in the bones and other organs as the result of extirpation of the thymus gland. He described experiments conducted on rabbits six weeks old, and the results he observed. When the thymus gland was removed in these animals, they recover very rapidly from the operation and become more vigorous than others of the same brood. They are more active and energetic, eat more, and increase in weight at a quicker rate than normal. They are also healthier than normal rabbits, and are rarely attacked by favus and other parasitic diseases to which normal rabbits are very subject. After extirpation of the thymus gland the rate of growth of the bones was demonstrated by lantern slides made from sections. These showed the activity of the formative process as compared with that of normal bone, which was also shown for comparison. There is no change in the bone marrow nor in the spleen after removal of the thymus gland, but the thyroid gland is enlarged, its alveoli are smaller, its structure becomes infiltrated with leucocytes, and it looks paler in colour. To some extent it takes on the function of the thymus gland. In contrast to this, when the thyroid is extirpated the thymus gland atrophies and disappears, and in Grave's disease the enlargement of the thyroid is accompanied by an enlargement of the thymus gland. An animal can live without its thymus gland or without its spleen, but when both these organs are extirpated death always occurs immediately. The thymus gland plays a part in the processes of metabolism and in the causation of some diseases, although that part cannot yet be accurately defined. Sufficient is known, however, to suggest certain means of treatment in some diseases, and this demonstrates the practical importance of these experiments. Several conditions can be benefited by extirpation of the thymus gland, while others can be improved by feeding upon this gland or an extract of it. Thus rickets has been benefited by giving thymus gland or its extract, and improvement in exophthalmic goitre is often marked when treated by this means. When this does no good in exophthalmic goitre, the thymus which is usually enlarged should be extirpated before the thyroid gland is interfered with. Extirpation of the thymus gland has been found of benefit in some cases of laryngismus stridulus, and does not interfere with the normal development of the child.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD FRIDAY, FEBRUARY 21ST, 1908.

The President, Dr. A. J. WALLACE (Liverpool), in the Chair.

DR. **W. BLAIR BELL** exhibited a new portable operating table.

Dr. **MILES H. PHILLIPS** (Sheffield) showed a specimen of the uterus in which there was an unusual degree of cystic degeneration of the cervix. It was removed by vaginal hysterectomy from a patient, æt. 48, who had had one child 27 years ago. Menstruation, which had always been regular, of 4 days' duration every 28 days, had ceased abruptly six months ago. For the past five months there had been occasional pain in the right iliac and hypochondriac regions, but never severe. On two occasions vaginal examination had caused hæmorrhage. The cervix uteri was found to be enlarged from the presence of cystic cavities, measuring 8-12 mm. in diameter, situated chiefly in the posterior lip. They were filled with mucoid material. The cervical mucosa was normal, as was also the corpus. Microscopically the cysts were shown to be dilated cervical glands, lined by a single layer of columnar epithelium. There was a great preponderance of fibrous tissue surrounding the glands, and Dr. Phillips regarded the condition as due to a fibrosis of the supravaginal cervix leading to closure of some of the gland ducts, and retention of their secretion, comparable to involution cysts of the breast.

Dr. **LLOYD ROBERTS** (Manchester) recorded a case of Cæsarean section successfully performed on a patient, æt. 25, who was the subject of pelvic deformity due to achondroplasia. He also gave particulars of a ruptured ovarian cyst occurring in a nulliparous woman, æt. 52. At the operation evacuation in the usual way by trochar was impossible, owing to the gelatinous nature of the contents. The wall of the cyst had ruptured, and similar material filled the peritoneal cavity. The patient made a good recovery.

Miss **FRANCES IVENS** (Liverpool) related a case of pregnancy complicated by bilateral ovarian dermoid cysts, occurring in a nulliparous woman, æt. 35. Menstruation was always regular, and ceased in February, 1906, and the patient sought advice five months later, thinking herself to be pregnant. On examination a cystic swelling the size of a tangerine orange was found lying low in the pelvis beneath the pregnant uterus. On opening the abdomen, the opposite ovary was found to be the seat of a similar but slightly larger tumour, also dermoid in character. It was possible to enucleate both cysts, leaving all healthy ovarian tissue behind. Recovery was uneventful, and the pregnancy was uninterrupted.

Dr. **GRIMSDALE** (Liverpool) communicated a case of carcinoma of the cervix uteri complicating a three months' pregnancy in a patient, æt. 36. There had been loss of flesh and a sanious discharge for three months. Abdominal hysterectomy was performed, and the patient made a good recovery. Mr. George G. Hamilton showed a photograph of the specimen taken by Lumière's colour process.

Dr. **E. EMRYS-ROBERTS** (Liverpool) read a short note on cell dehiscence in pseudomucinous cysts of the ovary, illustrated by colour drawings. He described the epithelial lining of these cysts as being—(1) typical, and (2) atypical, the former being the more frequent, although both varieties were occasionally met with in the same cyst. He drew attention to the changes in the epithelial cell during the formation and extrusion of pseudomucin, and thought it highly probable that the so-called "ovarian cells," or Drysdale's corpuscles, were really aggregations of pseudo-mucin granules, and that their identification would have borne out the contention of their describer as being pathognomonic of this disease of the ovary. The process of cell dehiscence was also described, as occurring especially in cysts lined by more than one layer of epithelium. In the atypical variety cell dehiscence is especially marked, and represents the last stage in the life history of the epithelial cell. The living cell is capable, not only of the production, but also of the extrusion of pseudo-mucin; the dead cell is filled with the substance which it cannot extrude, hence it ceases to be any longer a uni-cellular gland, and, tightly distended, is shed into the lumen of the gland acinus.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 1st, 1908.

BEE STINGS.

THE effects of a bee sting are generally local and benign, but sometimes it produces very grave accidents, indicating profound intoxication of the organism.

A medical paper relates, in this connection, the following fact: A man, æt. 57, of strong constitution, was watering flowers near a beehive, when he felt himself stung on the back of his neck and on the top of his head. He rubbed the parts with some aromatic plant, and continued his work. But soon he was seized with vertigo, and went into the house when he fell into an armchair. A few minutes afterwards he became of waxy colour, and was threatened with coma. Summary measures were employed by the family, and consciousness returned. A doctor arrived a quarter of an hour afterwards, and found the pulse beating at 20 per minute and six inspirations. During the day the pulse went up, and the following morning the condition was normal. The stings were not painful nor was there any local inflammatory reaction observed. Syncope supervened ten minutes after the stings, and lasted about the same period of time.

It seemed that for some years this man was peculiarly sensitive to the venom of bees, and when he handled the hives urticaria appeared some hours afterwards.

Another case differed from the preceding by the absence of grave nervous disturbance, and was characterised more especially by vague malaise and general urticaria.

A woman of 55, of healthy constitution, was stung by a wasp. Ten minutes after the sting she complained of great itching over the region, and soon vesicles of the size of a five shilling piece appeared *loco dolenti*. The eruption spread over the body, but the bullæ were smaller. Four hours after the accident these disappeared, and the following day only a slight erythema over the knees and the palms of the hands was observed.

Dr. Lamarche made a communication on bee stings recently before the Société de Médecine de Lyon. He said that he had for many years been interested in the beehive industry, and from being frequently stung he was rendered immune to the poison. According to him seasons and temperature influenced the character of the bees. They stung seldom while gathering the honey, and when they have well eaten they are gentle. The dart always remains in the wound with the reservoir of venom. The males have no sting, while that of the female is inoffensive. He advised that no pressure should be exercised on the little wound until the reservoir holding the venom (formic acid) attached to the dart was resected.

LOCAL TREATMENT OF DIPHTHERIA.

Large irrigations by means of an irrigator should be practised in each case of diphtheria in order to remove the mucosities and portions of false membranes which encumber the pharynx. The nature of the liquid is more or less immaterial, as it is chiefly the mechanical action that should be desired. Boiled water, a solution of chloral (5—1000), or oxygen water (2—100) might be employed. These liquids should be used warm, as heat relieves the pain, and in large quantity, one quart at least. The injections should be repeated every two hours.

At the same time, spraying the parts with some antiseptic solution is advisable—

Thymol, 1 dr.
Phenol, 5 dr.
Proof spirit, 3 oz.
Water, one quart.

Beyond these irrigations and sprays the local treatment amounts to but little. At least the above is that employed in the Paris hospitals.

However, many practitioners apply directly divers solutions, as—

Perchloride of iron, }
Alum, } āā ½ dr.
Boric acid, }
Glycerin, 5 dr.

Or,

Menthol, 20 dr.
Camphor, 10 dr.

Or,

Menthol, 6 gr.
Camphor, 3 gr.
Olive oil, 3 oz.

A teaspoonful poured into each nostril three times a day to insure antisepsis of the superior respiratory tract.

Paralysis resulting from diphtheria is best treated by repeated injections of anti-diphtheritic serum. The injections should be made for several consecutive days by 10-gramme doses until 60 or 80 grammes are reached, irrespective of age or previous condition.

M. Dopter recommends the use of lozenges prepared with the serum. Their use would bring about, in a few days, the disappearance of the bacilli of Loeffler from the throat.

GERMANY.

Berlin, March 1st, 1908.

AT the Verein für Innere Medizin, the discussion on TUBERCULIN REACTION was continued.

Hr. Martin spoke from a gynæcological point of view. Twenty-five tuberculous pregnant women were tested with the ophthalmic reaction, and in every case the result corresponded to the actual condition. In 10 women the test was repeated 10 weeks later, with a similar result.

Hr. Muscat thought the procedure very valuable for the practising physician. Since November he had applied the test in about 80 cases. At first he used Calmette's preparation, but more recently the German one, since it had been supplied in ampullæ, each ampulla containing enough for one test. The patients he tested were out-patients, so that the test could not be controlled within the first 15 or 18 hours, as it ought to be, so as to avoid missing the height of the reaction. His experiences corresponded to those of others: 87.5 per cent. of tuberculous cases reacted to the test; in 31 non-tuberculous cases a positive reaction was met with only once. Of suspected cases 76 per cent. gave a positive reaction, a proof that not all apical catarrhs were tuberculous.

Hr. Möller claimed that the test by subcutaneous injection was not dangerous. In ten years he had employed it in 30,000 cases, and had never seen mobilisation of the tubercle bacillus, nor had ever met with a disagreeable accident, even in out-patients. It would be a misfortune to displace injection by the ophthalmic reaction, as with the latter we were able to bring about recoveries. In using the ophthalmic reaction he had always to ask himself—what is a positive reaction and what is a negative one? A slight reaction might be shown by dropping a different fluid into the eye, but with subcutaneous injection the thermometer always declared the certain result. He had tried the ophthalmic reaction in 12 cases; sometimes the result was positive and sometimes negative. Many patients objected to the test, as it had got spread abroad that it caused inflammation of the eyes.

Hr. Levy had tried the test in 120 cases in the surgical department of the Israelitish Hospital. The results agreed on the whole with those obtained in the medical department. The result was positive in 62 per cent. of the cases; in quite a number it was doubtful. As regarded misfortune attending it, severe purulent ophthalmia was observed in two cases, and in one it was bilateral. It was worth considering that the subcutaneous method by injection could not be made use of after it. Therapeutically it was, of course, of no value.

Hr. L. Casper reported on the following case: Four weeks ago a female was sent to him with pus in the urine. The family attendant stated that tubercle bacilli had been twice found in the urine. Otherwise the lady was quite well; she was not suffering, and, above all, there was no hæmaturia at any time. On palpation the left kidney was found to be considerably enlarged, but there were no tubercle bacilli in the urine. The patient was now cystoscoped, with the surprising result that the urine from the enlarged left kidney was quite clear, but that from the right was purulent. Here the ophthalmic reaction was tested, and the result was positive. The patient, who had already heard something, now urgently begged for an operation, to which Hr. Casper, although he was not completely satisfied about the tuberculous condition of the kidney, consented. After exposing the kidney, 12 calculi were found in the pelvis of the kidney; there was no trace of tubercle. Naturally, the kidney was not removed, and the patient was now quite well. To the favourers of the new diagnostic method he would recall the words of the poet, "Der Wahn ist kurz, die Reu' ist lang" ("The madness is short, the repentance long").

Hr. Levy recommended the Höchst preparation, the Alttuberculin, in preference to that of Calmette, and the degree of concentration should be from 1 per cent. to 4 per cent. Slight, ordinary conjunctivitis was not a contra-indication, but with follicular conjunctivitis and after trachoma it should not be used. As regarded a positive reaction in non-tuberculous cases, in five typhoid cases he had met with it once, but never in acute rheumatism, although he had examined a large number of cases, and not once either in pneumonia or influenza.

In his reply Hr. Stadelmann pointed out that it was important to discover why the reaction appeared in some cases and not in others.

Hr. Citron pleaded for weak solutions. It was the same with tuberculin as with Widal's reaction in typhoid. It was an undeniable fact that the greater the degree of dilution was, the more specific was the reaction.

The President (Hr. Kraus), in closing the discussion, said that a good deal of importance must be conceded to the ophthalmic reaction, but the results of further investigations must be waited for. For the present, at any rate, its introduction into general practice was not to be recommended.

AUSTRIA.

Vienna, March 1st, 1908.

"Beckenflecken."

At the "Gesellschaft" Robinsohn gave a long description of this latest novelty in Röntgenology, which was first brought to the notice of the profession by Albers-Schönberg in cases of ischialgia or sciatica. These spots or shadows seen by the rays are located to the spina inferior ossis ilii, and the Pass horizontalis ossis. They appear as spherical balls of chalk or other concretions, which have given rise to a number of theories, each with its appropriate name according to classification; Phlebolithia suggests the origin from the veins, lymphatic calcification, intra-muscular calcification, and pedicular exostosis.

Robinsohn believes these "beckenflecken" to be a morbid process affecting the pelvic nerves, which alter the function of the pelvic organs, particularly the urinary apparatus.

In order to demonstrate this opinion he brought forward a male patient, æt. 28, who had a severe attack of gonorrhœa eight years ago, and is now a martyr to bilateral ischialgia. Every form of treatment has been unavailing, and the agony is still being borne. In this case the "beckenflecken" or pelvic shadows are present on both sides, viz., in the spina ossis ischii posterior and the horizontal rami of the pubis. In these positions multiples of concretions are found forming typical pelvic spots with the Röntgen rays, which he considers act as gonorrhœic synovitis on the serous membranes of the pelvis, and probably in the sheaths of the nerves.

Bum thought we could hardly object to Robinsohn's argument, as the compression phenomena were very prominent in the disease, judging from the severity and constancy of the pain. We have always been inclined to favour such an origin as the deposit of chalk crystals as an old theory.

Winternitz said that as long as it is not proved what these concretions are, we cannot rashly conclude that we have yet arrived at the cause of ischialgia. Are these concretions composed of uric acid or its salts, and why do the joints go free while special nerves are afflicted in the pelvis? As yet we have only the testimony of radiologists to support the theory. Again, how comes it that ischialgia can be cured without the diminution or dissolution of these so-called pathological spots? The compression is likely to remain as long as those concrete masses are present, and the ischialgia to continue.

Altered Secretion and Extirpation.

Epping-Falta and Rudinger have been experimenting with animals by removing the thyroid gland to measure the metabolic changes after the operation. In a dog the albuminous metamorphosis is reduced by one-half the normal amount, but the carbohydrates and fat are not altered. In those animals where the thyroid is removed, it does not require any more adrenalin injected into the peritoneum to produce glycosuria, as in the normal animal. If glycosuria be produced by administering adrenalin before the extirpation of the gland, the glycosuria will reappear after the operation, though it may temporarily have disappeared. If adrenalin be administered and the pancreas removed, the glycosuria is not reduced, but decidedly increased. It is important to note that adrenalin is active in the dog after both thyroid and pancreas are removed. He considers the mobilising of the carbohydrates by the adrenalin stands between two antagonistic influences, the thyroid promoting and the pancreas inhibiting.

Empyema of Frontal Sinus.

Hajek presented two cases of severe chronic empyema which he successfully treated by Kilian's operation. One of them came to him with an enormous swelling in the orbital cavity apparently originating in the frontal sinus which was freely laid open and cleared out, taking care to remove the trochlear attachment carefully. After the operation the trochlear has a rapid, trembling movement, but is otherwise functionally intact. It has always been held that this operation is impracticable, owing to the double vision that follows from the displacement of the trochlear attachment. This danger is not so great as was represented when proper care is taken to disturb the superior oblique as little as possible. It may be noted here that this operation is a modification of Kilian's which Hajek maintains preserves the obliquus.

Microscopic Milk Analysis.

Kreidl showed a number of ultra-microscopic preparations of milk from different animals, such as the reindeer, the cat, the dog, the guinea-pig, the rabbit, etc., which he compared with human milk. The latter differed from all the other animals in not having a corpuscular element which was constantly present on the dark field with the other animals. In human milk a fine granular or molecular substance is present in the plasma, possessing the Brownian movement. These fine particles Kreidl names "Tröpfchen Laktozonien."

Escherich thinks this may be due to the animals having more inorganic salts than the human subject.

HUNGARY.

Budapest, March 1st, 1908.

The Association of Apothecaries and Druggists has decided to give up the preparation of anti-diphtheria serum. The work is, however, to be taken up by the Municipal Experimental Bacteriological Institute for one year as an experiment. It will be carried on in the same laboratories and with the help of the same scientific staff as heretofore. The Association has for some years past issued from 2,000 to 3,000 doses of antitoxin of 1,500 units each, most of which has been used in the hospitals of the University of Budapest.

In 1898 the pediatricians of these hospitals undertook the bacteriological examination of diphtheria cases. The object was that the treatment might be tested on a large scale. At that time the serum was yet regarded with considerable doubt, not only by the public, but also by not a few members of the medical profession, and it was believed that if the serum were prepared with the sanction of the Association of Apothecaries, controlled by the Medical Society, more confidence would be felt in the remedy. The present Municipal Institute has no profit out of the work.

A CASE OF RABIES DUE TO PREVENTIVE INOCULATIONS.

In a Hungarian medical journal a case was reported in which a doubt existed as to whether the symptoms were due to the bite of a rabid dog or to the preventive inoculations. A woman, æt. 45, was bitten by a young dog, which was almost immediately killed, without having given any evidences of having had rabies. The patient was given Pasteur treatment, 24 injections being made within 12 days, beginning five days after the injury. On the eighth day of treatment a series of symptoms came on, regarding which it was doubtful whether they were due to true rabies or the inoculated modified form—malaise, nausea, slight cerebral disturbance and stupor. These increased in severity, and were accompanied by obstinate constipation, paralysis of the bladder, dyspnœa, mental depression, with paresis of the face, tongue and pharynx. Gradual improvement came on after a month, but then she became melancholic, and finally a complete idiot, dying within ten months after the injury. It seems probable that in this case the symptoms were due to the inoculations, for the disease began to show itself within 13 days after the bite, which is unusually early, particularly as the injury was superficial. Another servant in the same house was more severely bitten by the same dog, but was not treated, and remained perfectly well. The dog, in all probability, was not mad. The case is of interest because the symptoms could be traced without much question to the inoculations, and the production of such a modified form of the disease has usually been ascribed by other authors who have observed it to the character of the bite itself. The author thinks that if the treatment had been continued so that a true immunity was developed the woman might have been saved.

At the recent meeting of the Medical Society, Dr. Ladànyi read a paper on the

TREATMENT OF BASEDOW'S DISEASE.

He advocates the milk treatment, which gave very excellent results in his cases. This treatment consists of feeding patients afflicted with exophthalmic goître with milk from thyroidectomised goats, and is based on the theory that in thyroid cachexia a poison is circulated in the organism, which, if used in Basedow's disease, might have an antagonising effect on the poison of this affection.

Dr. Ladànyi had a particularly severe case, the exophthalmos and the goître being very prominent; there were considerable emaciation and choreiform movements. The milk was given in various quantities from 1 to 1½ litres daily. Improvement was slow, but constant, and in three months she gained about 6 kilos. The author believes that, instead of the milk having a direct antagonistic action, the process is one of neutralisation (as already stated also by Dr. O. E. Lademann in America), or possibly combination, and the effect lasts only as long as the milk is given. Moreover, the severer the exophthalmic goître, the more milk is required to neutralise. He does not consider that this treatment is specific for Basedow's disease, but believes that further observations are necessary to establish its value. He would also suggest to use desiccated thyroidectomised milk in the form of tablets, if these were obtainable in Hungary.

THE VENTILATION OF RAILWAY CARS.

The State Railways have, after a period of experimentation, adopted a device for ventilating their passenger coaches which promises to do away, not only with bad air, but also with the overheating and underheating of the cars, three evils from which every passenger has at some time or other suffered. The description (in the engineering papers) of the device, indicates that there is about it nothing that is severely complex. Outside air is brought into the car through hoods covered with wire gauze to exclude cinders, passed through vertical down-takes to a space under the floor, whence it is driven into the heater boxes and warmed by the radiators. From the heater boxes the air passes into the car, performs its mission, and is allowed to escape through the ventilators. When all the ventilators are open, 40,000 to 50,000 cubic feet of fresh air can be provided per hour.

The tests on the Hungarian fast trains have been so satisfactory that several dozen cars have already been equipped with the device. If all that is claimed for the system is true, its general adoption, it would seem, cannot long be delayed.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

GLASGOW UNIVERSITY CHANCELLORSHIP.—Lord Rosebery has consented to be nominated as Chancellor of the University in succession to Lord Kelvin. The nomination, which is unanimous, will take place at the statutory meeting of the Court on April 1st.

CARNEGIE TRUST AND THE SCOTTISH UNIVERSITIES.—In order to bring the financial year of the Trust into line with the academic year, the present report covers a period of nine months only, concluding at September 30th, 1907, instead of covering the whole of the year. The quinquennial system of grants in aid of equipment, inaugurated in 1903, closed on December 31st, 1907, and will be reported on in next year's report. It is hoped that before long the Executive Committee will be able to announce their decisions as to a second quinquennial scheme. The expenditure on endowment of post-graduate study and research was £7,003 in 1906-7, and the estimate under the same head for the current year is £7,615. Owing to this being merely an interim report, not including the expenditure on class fees during the winter session, comparisons cannot be made with previous years. The average fee per student has, however, risen from £6 16s. 8d. to £7 2s. 7d. The Trust have been negotiating with the Universities concerning the possibility of coming to some arrangement as to fixity and equality of the fees chargeable to the beneficiaries, such as the institution of a scheme of inclusive fees. The University of Aberdeen has declared itself against such a project; St. Andrews is generally in favour of it; while Edinburgh and Glasgow have definitely proposed to institute an inclusive fee in the Faculty of Arts. The total income of the trust for the year was £71,749 5s. 7d., and the expenditure, management, £2,164 2s. 7d., leaving a net revenue available under Head A—payment of class fees, £34,792 11s. 6d.; under Head B—improvement of equipment, £34,792 11s. 6d.

CHAIR OF CLINICAL SURGERY, UNIVERSITY OF EDINBURGH.—Owing to legal difficulties which have arisen in connection with the fact that the holder of this Chair will be compelled to resign his charge of wards in the infirmary at the age of 65, which will prevent his being appointed to the Professoriate for life, as in the case of other professors whose teaching is not absolutely dependent on their having clinical material, it is probable that some little time may elapse before Professor Annandale's successor is appointed by the Crown.

BELFAST.

PUBLIC HEALTH.—The death-rate last week in Belfast reached the alarming figure of 30.7, the rate from zymotic diseases being 2.1, and from chest affections 6.6, above the corresponding period last year. There were eight cases of cerebro-spinal meningitis notified, as against six the previous week. There are now 22 cases of this disease in the Purdysburn Fever Hospital, and there were two deaths from it in hospital during the week. An interesting report was presented at the last meeting of the Public Health Committee, giving an account of a five days' tour in the country round Belfast made by one of the officials of the department for the purpose of inspecting the sources of the city's milk supply. The general drift of the report is that there is simply no attention paid to sanitation or cleanliness in the cow-sheds, and that the cattle generally are poorly bred and poorly fed.

LETTERS TO THE EDITOR.

TINKERING MEDICAL LAW.

To the Editor of The Medical Press and Circular.

Sir,—The wretched Bill to prevent fraudulent medical practice under the cloak of the Companies Act, which was examined into, with full exposure of its futility, before a Select Committee of the House of Lords a year or so ago, seems to have been revived by Sir J. Batty Tuke, M.P. A Bill with a similar title has, at any rate, been brought forward by him in the Commons. Sir J. Batty Tuke is much too serious a man to be charged with wishing to amuse himself in this procedure; but it is difficult to imagine what, excepting his own personal amusement, he expects to get out of it. There exists not the remotest chance of the Bill becoming law, and it is amazing that he has not realised this. If it became law, moreover, the only effect would be to put to temporary inconvenience less than 5 per cent. of the rascals practising as doctors under false pretences. They would need only to drop the term "Limited," and reconstitute themselves "unlimited," or cease to use any term of the kind. To advertise effectually a quack need only announce "Dr. Bogus's treatment," or "Dr. Bogus's electrical apparatus," or "Dr. Bogus's cure for cancer, consumption," etc. The advertisements offer advice; the patients who apply believe they are consulting the fictitious doctor; and the quack, with quite unnecessary caution, avoids using terms implying that he is qualified. There are half-a-dozen other ways, all equally easy, and sufficient, and all being employed on a large scale to effect the same purpose; and Sir J. B. Tuke's Bill, if it became law, would not inflict more than the most trivial of pin-pricks upon that huge monster, fraudulent quackery. I am among those of your readers who thoroughly agree with your contention that the only way to strike a deadly blow at fraudulent quackery lies first in authoritative exposure, and then in a demand for sweeping legislation. The suggestion first made in your admirable paper by Mr. Henry Sewill that a Royal Commission should be demanded, has been proved thoroughly practical by the result of the Australian Commission; and the fact pointed out by one of your correspondents this week that a Commission on whisky has just been appointed ought to encourage you, and those who are working with you, to promote Mr. Sewill's project. The quack medicine trade—a cloak for quack practice—and practice under other fraudulent pretences, are inflicting vastly greater injury upon the public than is caused by the sale of inferior whisky. The case for a Royal Commission on quackery is literally a thousand times stronger; and it is to be hoped that you, Sir, will persevere in the campaign you have so well begun until the profession, by a united effort, brings it to a successful termination.

I am, Sir, yours truly,
Another Reformer.

Manchester, February 28th, 1908.

CHRISTIAN SCIENCE.

To the Editor of The Medical Press and Circular.

Sir,—Those of your readers who were previously unacquainted with the professions and claims of Christian Scientists must have received full enlightenment from Mr. Dixon's letters, and especially from his last, published in your issue of to-day, and it seems quite unnecessary to prolong the discussion in your pages. I repeat we have little to do with Mr. Dixon's theology; but we can all recognise that, viewed in the dry light of science, his statements form a string of grotesque absurdities. The pith of it all is a claim to cure all diseases by miracle, although Mr. Dixon admits in passing that there is such a thing as "an incurable disease." Nevertheless, "cancer, epilepsy, and consumption are being destroyed by Christian Science every day," and no doubt organic degenerations are by the same means being done away with, and destroyed or obliterated tissues are being restored to their primitive intact physiological condition. To bring all these things about by the methods of Christian Science would not be as wonderful as to prevent by similar means the effects of a lethal dose of arsenic or strychnine, to set a fractured bone, or extract the missile from a gunshot wound. Those with the ignorance of true science, and the faith in Christian Science displayed by votaries of that cult, may accept Mr. Dixon's statements; but these ideas will be always rejected with scorn by the medical profession, and exposed and denounced on every possible occasion as pernicious nonsense.

I am, Sir, yours truly,
Henry Sewill.

THE MILK SUPPLY OF HOSPITALS.

To the Editor of The Medical Press and Circular.

Sir,—The reports of Surgeon-Colonel Flinn and of Dr. O'Donoghue before the North Dublin District Council, recently published in the daily Press, taken in conjunction with the report of the Central Hospital Council for London on the milk supply of the London Hospitals, provide food for reflection. In this last-mentioned report a number of recommendations are suggested, having the object in view of minimising the chances of adulteration of the milk and also of reducing the possibility of infection through the medium of this important article of diet. However advisable such precautions may be in London, their adoption is even more urgent in Dublin, in the light of the reports of Surgeon-Colonel Flinn and Dr. O'Donoghue.

It will be readily admitted that amongst the adult population the greatest sufferers from impure milk are the patients of our hospitals, for the effects of either a reduction in its nutritive qualities or an increase in its bacterial contents would obviously be felt most severely by organisations whose powers of resistance had been reduced by the ravages of disease. It is very evident that the time has arrived to do something towards the improvement of our milk supply, and no more fitting start could be made than by securing a supply of pure milk—pure in the bacteriological as well as in the chemical sense—for our hospitals.

Considerable facilities exist in this city for such an experiment that are absent in the case of London. In the first place, the source of the supply is in most cases within easy distance of the hospitals themselves, thus obviating the necessity of the long railway journey which, especially in summer, militates so strongly against the chances of receiving milk in a condition of even comparative freshness. Secondly, the hospitals of Dublin are relatively few in number when compared with those of London, and consequently their area of supply could be much more restricted than would be possible in the case of the hospitals of the larger city. The great advantage which would accrue from such a centralised supply would be, of course, in the facilities offered for frequent inspection of the sources of supply by the hospital authorities themselves.

What I would suggest is that the hospitals should agree to unite in giving their contracts to a few dairies, run upon the most approved hygenic principles; and open to inspection by inspectors appointed by the hospitals at frequent intervals; the purity of the milk being controlled by the aid of frequent chemical and bacteriological analysis. Needless to say such dairies would require to be conducted by persons who possessed a practical scientific training, combined with a knowledge of dairying.

I make these suggestions in no academical, but in a practical, spirit. In my own knowledge there exist facilities for the formation of at least one such dairy, and a practical lead having been given, there is little doubt that others would spring up to meet the demand which would inevitably arise.

The chief features of such a dairy would be :—(1) Special care as to the cleanliness of the cows, combined with frequent veterinary inspection. (2) Periodical medical inspection of all concerned in the handling of the milk. (3) The sterilisation, by the use of live steam, of all vessels used. (4) The distribution of the milk in sterilised sealed bottles of a pint or quart capacity. (5) The pasteurisation or buddeisation of the milk in certain cases when required. (6) The publication of periodical reports, including chemical and bacteriological analysis.

There are many more details which consideration for your valuable space forbids me mentioning at present, but I may discuss them in a future letter.

I am, Sir, yours truly,
C. Jocelyn O'Hehir.

Mount Alton, Knocklyon, Templeogue,

THE THERAPEUTICAL SOCIETY AND THE ROYAL SOCIETY OF MEDICINE.

To the Editor of The Medical Press and Circular.

Sir,—Will you kindly allow me short space to make a personal explanation? As soon as possible after the "Transactions" were published and the printers' account in my hands, I made up my balance account, and then wrote to Dr. Duncanson, saying that I should "have pleasure in handing over my accounts, etc., to the Royal Society of Medicine." The Council, of which he is secretary, met on November 24th. There was no cause, so far as I was concerned, why the treasurer's books, etc., were not at 20, Hanover Square, on the following day, November 25th. Dr. Hugh Woods will bear me out in this. As to any inconvenience caused by delay I know nothing, and have no responsibility therefor. When, in the end of January, the Secretary of the R.S.M. had an interview with Dr. Woods and myself the same statement was made, or rather it was so completely understood as not to require affirmation. Yet a little later I received a communication, by a circumlocutory route, that I should do something. I inquired what I could do more than I had already done? The answer was that I should change my attitude. Well, my attitude for these three months has been resignation. I am afraid I cannot change it yet.

I wonder at times where the Therapeutical Society is. It is like a river flowing through the desert, it disappears into the sand, and beyond the horizon springs issue. Are they the same river? When I meet Mr. Macalister he almost persuades me he has it under his keeping, with the others. But at other times other voices reach me, and I have my doubts.

I am, Sir, yours truly,
G. Crichton.

"THE ONLY WAY."

To the Editor of The Medical Press and Circular.

Sir,—In relation to your editorial in this week's issue of The Medical Press, you comment upon the successful action raised against the Hall Hygiene Company for damages. May I be allowed to mention that a similar action was raised against the same company some short time since by the Medical Defence Union on behalf of a "patient," but that the company, wiser then than later, paid the amount claimed into Court, and so avoided the extra penalty of publicity. The case just presented was brought practically as a result of our successful action, and after consideration of the solicitors of the Union, who were applied to by the legal advisers of the plaintiff. Where suitable evidence is brought before us, the Council would have no hesitation in thus acting, as the effect of such a verdict as that just given will cause unqualified practitioners to reflect if they have any wisdom. Other actions have been raised in previous years against quack vendors, and in one instance a very lucrative practice in "hernia specialism" was broken up by this means.

I am, Sir, yours truly,
A. G. Bateman,
Gen. Secretary.

Medical Defence Union,
4, Trafalgar Square, W.C.,
February 28th, 1908.

[We have much pleasure in drawing the attention of our readers to the above letter, and trust that medical men generally will help the crusade against quackery by reporting cases to the Medical Defence Union.—Ed. M. P. and C.]

NOTIFICATION OF BIRTHS ACT.

To the Editor of The Medical Press and Circular.

Sir,—The promoters of this Act were inspired by good intentions, but its provisions will not accomplish their objects. The storm of opposition in the medical profession that has been excited renders it very unlikely that it can be efficiently administered. There is, indeed, much in the Act that calls for amendment. The duplex nature of the duties imposed on the parent or guardian who is called on—(1) to notify to the Medical Officer of Health, and (2) to register the birth, is likely to seriously interfere with the important work of registration. Mr. Dudman, the Registrar of Births for St. Marylebone, has pointed this out, and, owing to the migratory character of large sections of our population, his apprehensions are well founded. The best solution of the problem would be to direct—(1) that registration by the parent or guardian within 36 hours of the birth of the child should be compulsory; (2) that on the day of registration the Registrar should notify the Medical Officer of Health for the district; (3) that medical men should not be compelled to divulge professional secrets.

Were these amendments embodied in an Act, the Medical Officer of Health would receive early information, whilst the sense of injustice now felt by the medical profession would disappear, and their loyal assistance in the preservation of life would be as zealous in the future as it has been in the past.

I am, Sir, yours truly,
John Fletcher Little, M.O.H.

Harley Street, Cavendish Square, W.,
February 22nd, 1908.

THE ST. GEORGE'S-NAUHEIM INSTITUTE.

To the Editor of The Medical Press and Circular.

Sir,—My attention has been called to a paragraph in the current issue of The Medical Press entitled "The Salt Water Cure." In this paragraph the following passage appears:—

"It will take its place by the side of such great institutions as the Sandow and the Nauheim, which, in their several ways, are doing so much for the relief of diseases, the origin of which has been hitherto entirely unknown to scientific medicine, and of which the treatment has been in consequence so completely at fault."

I should like to point out that the Nauheim Institute passed under the control of my colleague, Mr. W. de Marchott Hill, and myself three months ago, and that our first step on taking control was the cessation of all advertising in the lay press, and the avoidance of any methods not in the strictest accordance with medical ethics.

So far as the treatment at this Institute is concerned, the method of administration is in strict accordance with the latest scientific research, and that everything is done solely in conjunction with the medical profession, and all treatment administered here is on the recommendation of, and in collaboration with, medical men. The association of an Institute of which we, as medical men, are in charge, with such remarks as occur in the paragraph from which I quote, must, I feel sure you will see, be calculated to do us personally immeasurable harm. I should be glad, therefore, if you would give this letter the same prominence in your paper as you gave to the paragraph to which I refer.

I am, Sir, yours truly,
W. Bain.

"A SURREY DOCTOR" AND VACCINATION.

To the Editor of The Medical Press and Circular.

Sir,—In view of the confident manner that Dr. Gubb adopts in his criticism of Mr. West, in your issue of February 26th, I should be glad if you would allow me to ask him to explain how vaccination can afford any real protection against small-pox when it affords such little protection against itself?

As he is no doubt aware, there is ample evidence to show that the "protection" of primary vaccination wears out in twelve months, and the "protection" of any subsequent vaccination in three years.

This is a clear and straight issue, and I ask Dr. Gubb to give it an equally clear and straight reply.

I am, Sir, yours truly,
JOSEPH P. SWAN.

11, Scarisbrick Street, Southport, Feb. 29th, 1908.

OBITUARY.

CONOLLY NORMAN, M.D.DUB., F.R.C.P.I.,

Resident Medical Superintendent, Richmond District Asylum, Dublin

SELDOM has the hand of death fallen with more disastrous suddenness than when, on the afternoon of Sunday, February 23rd, it struck down Conolly Norman, just as he appeared to be recovering from his recent illness, and with years of usefulness, humanly speaking, before him. What so irreparable a loss will mean to his friends, to the profession, and, above all, to the institution of which for so many years he was the head, only time will show. Certainly, while the shock is still so fresh, it is impossible to estimate.

Conolly Norman was born on March 12th, 1853, at All Saints' Glebe, Newtown Cunningham, Co. Donegal, the fifth son of the Rev. Hugh Norman, who at that time held the living. He was one of a family of six brothers, only two of whom survive him. At Newtown Cunningham, and later at Barnhill, his youth was passed, as he was educated at home, either owing to delicacy of health or from some other cause, which means that to himself was due almost entirely the wide knowledge, amounting in certain directions to genuine scholarship, which he subsequently possessed. When only about 17 years of age he commenced the study of medicine, working at the Trinity College and old Carmichael medical schools, and at the Richmond Hospital, and he gained the licences of the Royal Colleges of Physicians and Surgeons of Ireland in 1874, as well as the licence in Midwifery of the Rotunda Hospital. Four years later he took the Fellowship of the Royal College of Surgeons, and in 1890 that of the Royal College of Physicians.

From the beginning of his medical career he devoted himself to the study of mental disease, in which he was to acquire so well-deserved a pre-eminence in this country. Shortly after qualifying, he was appointed Assistant Medical Officer at Monaghan Asylum, where he remained for over seven years, quitting it in 1881 to extend his knowledge by a period of study at the great Bethlem Royal Hospital. While there he established a lifelong friendship with Dr. G. H. Savage, now the acknowledged *doyen* of the speciality in the United Kingdom, but at that time Resident Physician at Bethlem. In the following year he obtained his first senior post, being appointed Medical Superintendent of Castlebar Asylum, and in the same year he married. He returned as Medical Superintendent to his old asylum at Monagham in 1885, and in 1888 he made his final change, being appointed by Lord Aberdeen to succeed the late Dr. Lalor in the charge of the Richmond District Asylum. Such rapid promotion indicates the reputation he was making, and it is common knowledge how well he justified it. Throughout his career the interests of the patients were his chief care, and on taking up work at the Richmond Asylum he at once began to re-organise the institution. How thoroughly this was done has been shown by the Chairman of the present Committee. Dr. Norman found the asylum a gloomy prison, the inmates regarded as offenders, and treated with restraint and suppression; he left it presenting "the twofold aspect of a hospital, where the sickly and infirm received the most beneficent care, and a hive of industry, where the bodily strong found occupation and relief. The "strait jacket" was abolished and the grounds thrown open, outdoor and indoor games instituted, the wards artistically decorated and brightened with pictures, and flowers, and music; workshops established in which nearly every article of clothing worn by the patients is manufactured by themselves, as well as many other things; an improved dietary and better clothing introduced, and the nursing staff properly trained, while their conditions of life were improved. Yet, successful as his work in this line was, he was not a mere administrator. but essentially a physician, and in both respects he recognised that a closed asylum could never afford the best means of treatment for every class of case, while for some it was unnecessarily costly—a point of great importance in view of the increasing numbers of the insane With a view to meeting these two difficulties, he visited the colonies at Gheel and Lierneux, and what he saw there led him to urge, as he did for some years past with voice and pen, the legalisation of some system of family care for the harmless insane.

Yet, notwithstanding the burden of his great responsibility, Dr. Norman found time to become distinguished as a specialist, and his opinion, well reasoned and level-headed, was much in request, not only as a consultant in private, but in the law courts. Perhaps, however, it was in connection with the Medico-Psychological Association that his more purely scientific bent found expression. From the time when his first paper appeared in 1878, a long succession of communciations are to be found in the pages of the Journal of the Association, of which for some years he has been co-editor, dealing with almost every subject connected with the speciality, and marked by a clearness of judgment, a wide knowledge and experience, and a precision of expression, which rendered them interesting and valuable. Wide as was his scope, it is as a clinician that he was at his best, and although he found time for a period to do pathological work, for some years past he laid increasing stress on the clinical study of psychiatry, which he believed to be unduly neglected in these countries. With his great experience and learning, and his original turn of thought, it was to be expected that he would work out the subject on his own lines, and thus he was no blind follower of any authority—his rejection of the current views of "dementia præcox" at the debate at the Oxford meeting of the British Medical Association is proof of this—and it is a matter of deep regret that a volume of clinical lectures which he was preparing for the press was incomplete at the time of his death. In the work of the Association he took keen interest, and held various offices in it—that of Secretary to the Irish Division from 1888 to 1904, when he vacated it on his election as President. The annual meeting held in Dublin under his auspices in the latter year was a signal success, and will be within the memory of many. Of recent years he was not so regular an attendant at the general meetings, but he was almost invariably present at those of the Irish Division, and readily contributed from his stores of knowledge to make them a success. Nowhere will he be more missed than amongst the friends and colleagues, to whom on those occasions he was so familiar and welcome a figure.

His professional eminence was also fittingly recognised last summer by the honorary degree of M.D. of the University of Dublin, a distinction which was, perhaps, the greatest source of gratification that has fallen to his lot in recent times, and by his election to the Vice-Presidency of the Royal College of Physicians of Ireland; but even the multitudinous interests of his profession were not enough for his many-sided mind. His knowledge of English literature amounted to scholarship, and he was a keen student of French, German, and Italian, a practical botanist, and a judicious collector of prints, portraits, old books, and antiques generally, which made his beautiful house a perfect museum. His personality was everywhere apparent, and, in the words of the President of the Medico-Psychological Association, "Conolly Norman was a clear, outstanding figure by himself, and, in his way, a perfect genius."

It is, however, as a friend that he will be chiefly missed, and his death has brought a terrible sense of loss, not only to his wife and relatives, but to many in no way bound to him by ties of blood. The Committee under which he worked, his assistants, both past and present, the attendants and servants, and even the patients, have been unanimous in expressing their affection and regard for him and their grief at his loss, while others, from the Lord Lieutenant down, have combined to pay the last sad respect to his memory. What the want of his kindly interest, level-headed advice, and cheery. humorous society means to his more intimate friends cannot yet be realised.

For the past twelve years Conolly Norman has suffered off and on from anginous attacks, which he himself was inclined to attribute to a form of beriberi, that disease having broken out in the institution at the time. The worry and responsibility of his duties, which he always took hardly, did not allow of much rest; but last autumn, after a holiday, he was better in health than he had been for a long time. At the end of last December, however, he developed influenza with bronchitis, and was obliged to give up work, and he only returned to his duties on the Monday before his death, looking well, and having regained weight. No inkling was there of the approaching end, and he appeared as well as usual when he strolled out on the afternoon of Sunday, February 23rd, only to fall and die after walking a couple of hundred yards, for, though help was immediately at hand, nothing could be done. So passed away, as he himself would have wished, a man whom there is none to replace, and whom the speciality, the profession, and the country could ill afford to lose.

HENRY ROBERT SILVESTER, M.D.Lond.

We regret to announce the death of Dr. Henry Robert Silvester, M.D., whose name is well-known as the author of the "Silvester Method" of recovering the apparently drowned, at Clapham Common, in his 80th year. Educated at King's College, London, he graduated B.A. in 1850, was admitted a member of the Royal College of Surgeons, England, in 1853, and proceeded to the M.B. degree, London, in 1854, and to the M.D. in 1855. Dr. Silvester, who formerly practised in Clapham, received the Fothergill Gold Medallion of the value of 50 guineas from the Royal Humane Society in 1883, on their adoption of the "Silvester Method." He was the author of several medical works.

SAMUEL ROOTH, M.D., R.U.I., M.R.C.S., J.P., C.C.

We regret to announce the death of Dr. Samuel Rooth, J.P., C.C., which occurred last week at Dronfield. Dr. Rooth was educated at Chesterfield Grammar School, under the late Rev. Frederick Calder, M.A., and afterwards at the medical schools of the University of Aberdeen, Queen's University, Ireland, Guy's Hospital, London, and at Paris and Vienna. His degrees were M.D., Queen's University, Ireland, 1863; M.R.C.S., London, 1864; and L.S.A., London, 1864. Dr. Rooth was for many years intimately associated with the public life of Dronfield. He served on the old local Board and the School Board, and later was appointed one of the managers of the Council School. He was for a long period the Poor-law Medical Officer and Certifying Factory Surgeon, positions which he only recently resigned, and he was also for many years Public Vaccinator for the Dronfield Registration Sub-District. He was appointed in May, 1895, a Justice of the Peace, and was a regular attendant at the Dronfield Petty Sessions. When the County Councils were first instituted he was Dronfield's first Concillor, being returned by a great majority, while afterwards he was re-elected triennially without opposition.

WILLIAM GANDY, M.R.C.S., L.S.A.

We regret to record the death of Dr. William Gandy, of Norwood. Dr. Gandy, who had been ailing for the past 18 months, died on the 13th of last month, at the age of 67. For 36 years he had practised at Norwood. Dr. Gandy was a member of the House Committee of Westminster Hospital, and also a Governor; Governor of Charing Cross Hospital; Governor of Middlesex Hospital; Governor of the Queen Charlotte Lying-in Hospital. At one time he was President of the Gipsy Hill Conservative Association, and for a period was medical officer to the Post Office for this district. Up to the time of his death he was Divisional Surgeon to the Metropolitan Police, and also was Surgeon to Court Alma of the Ancient Order of Foresters. He was Brigadier-Surgeon Col. of the Volunteer Batt. 2nd East Surrey Regiment, in which he had served for about 28 years. Dr. Gandy was born at Plymouth, the son of Mr. Thomas Gandy, the portrait painter, who was afterwards established in South Street, Park Lane. He was originator, with the Rev. A. Bell, of the Norwood Cottage Hospital, and had been Honorary Surgeon ever since its institution in 1882. He was also Honorary Surgeon of the Victoria Home, Central Hill.

REGINALD HARRISON, F.R.C.S.

We regret to announce that Mr. Reginald Harrison died on Friday, at 6, Lower Berkeley Street, Portman Square, at the age of 70. Educated at Rossall School and at St. Bartholomew's Hospital, he was admitted a member of the Royal College of Surgeons, England, in 1859, becoming a Fellow in 1866. He had been Surgeon to the Liverpool Royal Infirmary, Lecturer on Clinical Surgery in Victoria University, Examiner in Surgery at the University of Durham, and Lecturer in Surgery and Anatomy at the Liverpool Royal Infirmary School of Medicine, and was a life member of the Court of Liverpool University. In London Mr. Harrison was Consulting Surgeon to St. Peter's Hospital, and had been Hunterian Professor of Pathology and Surgery at the Royal College of Surgeons, England, of which he was a past Vice-President and member of Council. He had also been President of the Medical Society of London, was a Knight of Grace of the Order of St. John of Jerusalem in England, and President of the Metropolitan Street Ambulance Association. He was the author of various professional works, and otherwise a contributor to surgical literature.

GEORGE MONEY SWINHOE, M.R.C.S., L.R.C.P.

We are sorry to have to record the death of Dr. George Money Swinhoe, chief medical officer to the G.W.R. Works at Swindon, where 15,000 hands are employed Dr. Swinhoe, who had reached the age of 77 years, had suffered a great deal from gout, but he had been confined to his bed only about a week. Dr. Swinhoe went through his course of medical training at Guy's Hospital. When the Crimean War broke out he joined the medical staff of the 95th Foot Regiment, and went through the whole of the campaign, having some thrilling experiences, but coming out of the ordeal unscathed. On his return to England he had a practice near London for a short time, and then, exactly fifty years ago, he applied for and obtained the appointment of chief of the medical staff at the G.W.R. Works, Swindon. When he took up the duties the number of employees was 800; to-day it is 15,000.

SPECIAL ARTICLES.

ROYAL EDINBURGH ASYLUM REPORT FOR 1907. (a)

By Professor T. S. CLOUSTON, M.D., F.R.C.P.

Dr. Clouston, in his Report for the year 1907, stated that in the beginning of the year the number of patients was 837 (including 6 on probation), and that on December 31st the number was 743 (including 10 on probation). The admissions were 317, of whom 154 were men and 163 women. The total number of patients under treatment was therefore 1,154. The number discharged from the institution was 328, of whom 106 were men and 222 women. The number of patients who died was 83, of whom 40 were men and 43 women. The average number of patients resident during the year was 731.7, of whom 355.2 were men and 376.5 were women. The total number of admissions (317) was 100 fewer than the average of the past five years. The reason for this was the opening of Bangour Village, which had thus been able to receive most of the patients from the Edinburgh Parish Council. It was 22 years since there was so small a number of admissions. The number of private patients admitted was 134, which was considerably the largest number of this class that had been sent to the institution.

(a) Valedictory Report presented to the Corporation of the Asylum Feb. 24th, 1908.

Following the oldest and simplest classification of mental diseases, in which the elevated and excited were put in one category, and the depressed or melancholic in another, a very suggestive fact appeared when one compared the numbers of those two classes sent to the institution before 1890, the year of the great epidemic of influenza, and those sent since that time. From the year 1874, his first full year of office, up to 1890, the number of melancholics had never touched that of the maniacal. There were only 1,846 of the depressed in the 16 years, to 2,832 of the exalted, or 40 per cent. of the total, while in the 18 years since 1890 (inclusive) there had been 2,662 melancholics to 3,123 cases of mania, or 46 per cent. In 1900 for the first time the numbers of the depressed exceeded those of the excited, while in 1905 this was also the case. In 1896-97 and 1907 the numbers of both classes were equal. The depressing effect on the whole nervous energy of that scourge of humanity, influenza, was now fully recognised, and its direct effects, bad as they were, were scarcely equal to its indirect and distant consequences. Melancholia was not the only nervous disease predisposed to by influenza. Neurasthenic conditions, premature senility, various forms of paralysis, all kinds of neuralgic affections, and a general incapacity for work, both bodily and mental, had all been noticed as following influenza. It seemed as if no disease of whose effects there was any correct record had had such far-reaching evil effects.

He was glad to say that alcoholic excess did not appear in their list of the assigned causes of the disease in so many cases as usual. What did attract attention in their alcoholic statistics, however, was that women appeared about as frequently as men on the lists. Looking back over the past 10 years, the figures would decidedly tend to strengthen the idea that the women of the working classes had taken more to excess in drink of recent years than before. If this represented a general social fact, it was of bad import for the future of the population. The number and the proportion of the cases of general paralysis remained large, 40 cases having been sent to the institution during the year, and the number of women (14) was very much larger than used to be the case. The percentage of recoveries was 28.6, which was a low one as compared with their average of 38.5, but he believed this comparatively low percentage resulted from the fact that cases of a different class were now sent to mental hospitals from those who were sent 30 years ago among the poor. There were far more patients of the old, weakened and paralysed class sent than formerly. The number of deaths (83) was smaller in proportion to their population than usual, the percentage on the average number resident being 11.3, and on the total number under treatment, 7.2.

There were only 24 patients still in the institution who were there when he assumed office in 1873. One of these had been 60 years in the institution, and was now over 80 years of age. They suitably celebrated the occasion of her 60th year of residence, and she enjoyed herself very much. The only thing she bitterly resented was being thought old. For the first time in the history of the institution, the rate-paid class, Dr. Clouston went on to state, were fewer in numbers than the private class of patients. During the 35 years since he assumed office, knowledge of the nature and pathology of many of the forms of mental disease had greatly increased, and the terror and reproach of the disease were visibly lessening.

Dr. Clouston afterwards referred to his relationship with the staff of the institution, and with the Board of Management, and continued:—I find it harder to write this, my last report, than any of the 47 which I had written at Carlisle and here. To lay down one's official duty seems somehow to cut adrift from life's anchorage. The work of the institution has grown under my hand until some of it has quadrupled in amount. My old staff of assistant medical officers, over 35 in number, now scattered all over the world, have been to me not only helpers, but close friends. I cannot describe in words how loyal every one of them has ever been to me and to the institution, and it is a source of pride to me that they earnestly carry forward the work which they began here. It would be quite impossible for me even to indicate the feelings with which I shall finally leave the patients and my work. The institution has a great future before it for humanity, and my most fervent wishes and prayers will ever be for its continued prosperity.

REVIEWS OF BOOKS.

HYGIENE OF NERVES AND MIND. (a)

YET another of Professor Forel's interesting books has been translated into English, and so is accessible to an audience well familiarised with his writings. It is difficult to give an adequate review of this volume here, as it is impossible to discover the kind of audience for whom it is intended, and without knowing the standard it aims at, it is naturally impossible to discuss whether this standard is reached or not. On the one hand it seems unlikely that the volume is addressed to a medical audience, else it would not abound in such pieces of information as that "each half" or "hemisphere" of the cerebrum consists of three principal lobes, the frontal, occipital, and temporal," or that "lethargy is a sleep-like asphyxia, with limp muscles." Indeed, from the general tone and plan of the book, it seems more probable that it is intended for a lay audience. But if this is so, it is very difficult to understand why it should concern itself so much with discussions of such questions as apathy and Bethe's recent criticisms of the neurone theory, the origin of nerve fibrils, Müller's doctrine of the specific energy of the senses, the ecphoric action of engrams, etc. We protest against the current notion that these subjects have any relation whatever to mental hygiene, a notion that is productive of much harm in many directions.

It is hardly just, therefore, to criticise the book from a medical standpoint, though many views are presented as scientific which really rest on no basis of fact. Thus there is no critical evidence whatever for the view, expressed on p. 181, that "neurasthenia is an eminently hereditary disease," and, indeed, the opening sentence (p. 204) of the chapter on heredity frankly states that we know "precious little" about the subject; nor is there any reason to suppose that (p. 180) hypochondria rests on a strong inherited tendency to anxious, uneasy observation of oneself. Naturally, from this opinion, is the transition easy to p. 207—strong statements about the marriage of the mentally abnormal. The book abounds further with fallacious conclusions about the influence of parental alcoholism on the offspring, for which the author is notorious.

It follows that advice to the lay public, based on an antiquated psychology and on unproven data, is likely to be misleading, though we freely admit that it may be popular and well received by an audience holding similar assumptions. To state, for instance (p. 180) that it is a principal rule of hygiene to suppress the sexual impulse as much as possible, certainly accords with current educational teaching, though it ignores the fact that an enormous mass of evidence has been accumulated showing that a great part of the psychoneuroses can be directly traced to the misunderstanding of such teaching.

In our opinion no book on mental hygiene is likely to be of any practical value unless it is founded on modern psychology, which has in the past few years so revolutionised our conceptions of the human mind.

THE ACTION OF ALCOHOL. (b)

NUMEROUS books—good, bad and indifferent—have recently appeared dealing with the alcohol problem. It is a subject which requires thorough scientific exposition and absolutely unprejudiced treatment. The work recently issued by the Church of England Temperance Society is, we understand, a collection of articles which have appeared in one of the official periodicals of that body, and is said to have been written by a "hospital surgeon," but why the author should have masked his identity is not evident. His action has certainly impaired the value likely to be placed on his work, for we are of opinion that no book of this character should be issued by a scientific worker anonymously. The "side lights" deal with the nature of thirst, the influence of alcohol on the skin, the vascular system, and the regulation of heat in the body. The relation of alcoholism to arteriosclerosis and Bright's disease is also discussed. The most valuable chapters are those which deal with the inebriate and his management. The style is terse and attractive, and the writer is evidently a close observer of men and things, but the presentation is essentially "popular," and hence is scrappy and superficial. The work is evidently addressed to the unscientific layman, to whom it may be recommended. It is little less than a crime that there should be no index.

SYPHILIS AND SMALL-POX. (*a*)

A GREAT boon is undoubtedly conveyed to the medical profession by the Council of the Sydenham Society in the publication of these translations and reprints. The essays on the "Occurrence of Spirochætes in Syphilis," by Drs. Fritz Schaudin and Erick Hoffmann (translated by Dr. T. G. Brodie); the abstract of a paper by Theodore Shennan entitled "Spirochæta Pallida (Spironema pallidum) in Syphilis"; the abstract of a paper by Dr. Aldo Castellani on the "Presence of Spirochætes in Yaws," and last, but not least, four communications giving the results of experimental investigations on syphilis by Elie Metchnikoff and Em. Roux (which embody the substance of the lectures given by the former savant in England)—all teem with interest and should be in the hands of every medical man. With reference to small-pox, an exhaustive treatise by Prof. Gary N. Calkins on the "Life History of Cytoryctes Variolæ Guarnieri"; a paper on "Epicrisis" by W. J. Councilman; and, lastly, "Clinical Observations on Variola," by Dr. T. R. Bancroft—form the second part of the volume, and furnish rich fields of observation and instruction.

PROSTATIC ENLARGEMENT. (*b*)

THIS book should prove of great interest to all surgeons, but more especially to those who make a speciality of prostatic diseases and operations. It embodies the results of investigations, the author explains, commenced in 1900 and undertaken to find a satisfactory solution of the operation known as "total prostatectomy." Whether a satisfactory solution has been found Mr. Wallace does not absolutely tell us, but he points out the various routes to be followed by the searcher after elucidation; for instance, when he writes concerning the operation on the encapsuled form and the non-encapsuled form, he says:—"Sufficient observation has not yet been made as to results of operation in the non-encapsuled form. . . . About the success of operative procedures on the encapsuled form there can be no doubt. . . . The position of the surgeon will be made much easier if the future is able to provide a certain means of diagnosis between the encapsuled and the non-encapsuled form." And again, in speaking of carcinoma of the prostate, he says:—"Time alone can show whether complete prostatectomy can give such results as to make it worth while submitting patients to such an ordeal." The chapter on Surgical Anatomy occupies 39 pages, and is of great value; it is embellished with 18 admirable illustrations; the next three chapters, which deal—(*a*) with the experimental pathology and function of the genital organs, (*b*) with the morbid anatomy, and (*c*) with the morbid histology, show painstaking research on the part of the author, and his close attention to the researches of others; and, again, here the illustrations leave nothing to be desired. Mr. L. S. Dudgeon next contributes a short but concise chapter on the bacteriology of the prostate, the tables on the bacteriological examination of the prostate and the urine in a series of cases being specially interesting. Mr. Wallace, in writing on the etiology, gives a list of nine theories of enlargement of the prostate, but pins his faith to three of them as being those best supported by facts—namely, (1) that it is due to a chronic inflammatory process; (2) that it is caused by a septic catarrhal process; and (3) that it is a neoplasm, giving his preference to the third. He brings forward nothing very new with regard to diagnosis and general treatment. In reference to operative treatment he puts aside (and we think with justice) vasectomy, castration, and operation on the pelvic floor, and considers that direct interference with the gland itself is, without doubt, the operation of the future. The remainder of the book gives the reader a description of the operation of enucleation as performed by a skilled surgeon, the illustrations being quite up to the mark of those before mentioned. The last chapter deals with carcinoma of the prostate, much stress being (with reason) laid on the difficulties of diagnosis. The book is very well got up, and the type is excellent, but we do not quite understand why the diphthongs are ignored, æ being given invariably as ae.

THE MUSCLES OF THE EYE. (*a*)

THIS treatise promises to be the most complete and comprehensive which has ever been attempted upon this special subject. In the volume before us the author first deals exhaustively with the general anatomy of the eye, and afterwards devotes ten chapters to the physiology of the ocular muscles. As showing the extent to which the author has pursued his researches it may be noted that in an appendix he adds a bibliography which includes no fewer than 41 pages of the work—a sufficient testimony to the thoroughness of his undertaking. The main objects of the author, as stated in his book, are to clear up the confusion of ideas which exist regarding the actions of the ocular muscles, and to insist upon the need of greater uniformity and completeness in methods of examination. He claims that at present most ophthalmic surgeons practice only a routine examination of patients suffering from asthenopia, heterophoria, and convergent strabismus, in consequence of which important details are overlooked, with the result that treatment proves to be unsatisfactory. The book is entirely one for the specialist, to whom, no doubt, the perusal will be found interesting and profitable. Scattered throughout its pages are many hints as to muscle action and testing of the ocular muscular apparatus, which cannot fail to be of use to the specialist in a practical sense. We can cordially recommend this work.

THE PHYSICAL TREATMENT OF CARDIAC DISEASE. (*b*)

OF recent years the so-called Nauheim treatment of heart disease has won considerable popularity, and in certain cases has proved of undoubted benefit. Mr. Dampier-Bennett's *brochure* should do something to advance its judicious application in this country under capable medical supervision. Much of his matter has already appeared in the *Practitioner*. The indications for and principles and methods of the treatment are dealt with on a basis of personal experience. The author is not desirous of restricting the cardiac subject to balneo-therapeutic measures, but would make use of regulated rest, massage, electrical applications and exercises. He also devotes a chapter to "Diet in Heart Disease," and gives considerable space to the consideration of "Drugs," so that the scope of the book oversteps the restrictions of its title. As an interesting expression of personal opinion the work is not without value, and practitioners will find many of the directions and suggestions of real service. There are no illustrations, which is a regrettable omission in a work dealing with physical methods.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

The Surgical Aspects of Subphrenic Abscess.—Barnard (*Brit. Med. Journ.*, Feb. 15th and 22nd, 1908) discusses the anatomical varieties, causes, signs, symptoms and treatment of subphrenic abscess. The communication deals with 76 cases treated at the London Hospital. The under-surface of the diaphragm is marked out into four peritoneal spaces and two cellular ones. The peritoneal spaces are separated from each other by the cruciform arrangements of the coronary and lateral, and the falciform ligaments, forming—(1) right anterior; (2) right posterior; (3) left anterior; and (4) left posterior areas. The extraperitoneal spaces are divided into—(5) right, and (6) left, the right being between the layers of the coronary ligaments, and the left in the perinephritic tissue around the upper end of the left kidney. Right anterior subphrenic abscesses occurred 27 times in the 76 cases, in 11 of which it was limited to this fossa. The commonest causes were: appendicitis, 10; liver abscesses, 7; perforated gastric ulcer, 4 cases. Ten cases of subphrenic abscess occupied the left posterior intraperitoneal space; 6 of these were due to appendicitis. These all occupied other spaces as well. Left anterior intraperitoneal subphrenic abscess occurred in 30 cases, 26 of which were confined to this region. The commonest cause was gastric ulcer (16 cases). There were 3 cases of infection of the left posterior intraperitoneal space, one of which was confined to this region. Right extraperitoneal subphrenic abscesses occurred in 19 cases, in 15 of which it was due to pathological conditions of the liver. Left extraperitoneal subphrenic abscess occurred in 4 cases, each of which was confined to this region. Two were connected with disease of bone, 1 with the stomach, and 1 with the lung. As regards treatment, the author says that the transpleural method of drainage, in which a hole is made into the diaphragm from above, is most unsuitable for early and diffuse stages of subphrenic abscess. An abdominal incision (usually in the loin) should be employed in these cases, and a long tube passed under the diaphragm from below. At a later stage, when the abscess is well shut off under the diaphragm, this route is not suitable, as the liver may be torn in separating it from the diaphragm or pus may be admitted to the general peritoneal cavity. The author says that the promiscuous search for pus with an ineffective syringe is dangerous and deceptive, but the proper use of a good aspirating needle, 3 inches long, on the operating table under a full anæsthetic is the most certain means of diagnosis. With the patient in the semi-prone position, the needle is passed deeply into the tenth intercostal space in the scapular line, and, if no pus is found, into the ninth, eighth, seventh and sixth spaces in turn. If no pus is found, the spaces are searched in the mid-axillary line, working from below upwards. Posterior methods of drainage give much more favourable results than anterior. Recent investigations in connection with diffuse peritonitis have shown that the main cause of subphrenic accumulations is gravitation, as the posterior extremities of the subphrenic spaces are only separated from the skin by about half-an-inch of tissue. As to the results obtained in the 76 cases, 36 died, or 47.4 per cent.; of the 64 cases operated on, 24, or 37.5 per cent., died. S.

Two Cases of Splenectomy.—Lieut.-Col. Dimmock (*Indian Med. Gazette*, Jan., 1908) reports two cases. The first was in a lady, æt. 23, suffering from prolapse of the spleen, which caused acute intestinal obstruction. Three years previously the spleen had been sutured up to the abdominal wall in its original position. Owing to the symptoms of obstruction, immediate operation was necessary. An incision was made to the left of the umbilicus, and on opening the thickened peritoneum, dark-coloured blood began to well up into the wound, showing that the tumour was adherent to it. The peritoneum was then opened above the adherent part. The tumour, which was found to be the spleen, had contracted extensive adhesion to the parietal peritoneum and to the intestines in three places. The adhesions were broken down with great difficulty, causing severe hæmorrhage, which was controlled by compressing the root of the spleen. The pedicle of the spleen was defined and ligatured, and the spleen excised. The cause of obstruction was found in a mass of adhesions to the right of and posterior to the spleen pedicle. Through this band a great part of the intestines had slipped, and a volvulus had formed. The condition was successfully treated. The patient made a complete recovery, and is not suffering from any enlargement of lymphatic glands nor any digestive troubles. In the second case splenectomy was performed for malarial splenomegaly. On palpation the spleen was felt occupying the whole of the left side of the abdomen. As it stood in imminent danger of rupture from the slightest injury, it was decided to remove it. The original medial incision had to be prolonged to from an inch below the ensiform cartilage to the symphysis pubis on account of the size of the tumour. The spleen was adherent in several places to the parietal peritoneum and to the mesentery. The adhesions were broken down between clamps and ligatured. The pedicle of the spleen was transfixed by two silk ligatures, which were tied, and the spleen removed. All bleeding points were secured and ligatured. The patient made a good recovery. The author lays stress on securing all bleeding points, especially those connected with small adhesions. Those under the arch of the ribs are frequently overlooked, and cause fatal oozing after operation. S.

Operative Treatment of Umbilical and Ventral Hernia.—Barker (*Practitioner*, February, 1908) points out that it is a good practice so to place the incision of the operation for ventral or umbilical hernia that the omentum can be removed *en bloc* with the sac and overlying skin, to which it is attached. The incision through the skin is made so as to only leave enough of it to cover over the wound; all the rest is removed with the sac. The latter is opened at a point least likely to have formed adhesions. This is usually near the neck on its upper aspect. The opening in the first instance should be only large enough to examine for adhesions, and to draw an extra quantity of omentum out of the abdomen. The omentum is tied off in strands, divided beyond the ligatures, and the stump reduced into the abdomen. When the ring is free, any gut having been replaced, the sac and skin are divided all round nearly flush with the skin level of the abdominal wall, and taken away with all the omentum still adherent to it. The next step consists of closing the ring, which is still clothed with the reflected edges of the sac. Stitches which include the expanded linea alba and the cut edges of the sac are passed through the edges, half an inch from the margins, and tied. The next procedure differs in the case of small or large openings. In the former case a broad line of union is obtained by stitching the front of the rectus sheath of one side to the other. In case of large hernias or in patients with very weak abdominal walls, the anterior layer of the recti sheath on both sides is opened longitudinally by a curved incision, starting well above the upper end of the first line of sutures, and terminating well below it. Wire netting is then laid over the first line of suture, which it should overlap above, below, and laterally. The edges of this netting rest on the anterior surface of the recti, and lie behind the anterior layer of the sheath. The recti sheaths are then united in the middle line. The skin is brought together as usual. The author has used this method in 20 cases with excellent results. Septic infection, should it occur, does not necessitate the removal of the wire network. S.

A Second Report on Clinical Experiences with Spinal Analgesia.—Barker (*Brit. Med. Journ.*, Feb. 1st, 1908) discusses the results in his second series of 100 cases of spinal analgesia. He points out, in contradiction to Continental workers, that gravitation is an important factor in the administration of the injection. He has succeeded by placing the patient on the left side, with the head and shoulders raised, in inducing anæsthesia of the left lower extremity alone, the left leg being amputated painlessly, while the patient had complete power and sensation in the right limb. Anæsthesia is induced by injecting 5 cgm. of stovaine in the second lumbar interspace. The specific gravity of the solution is 1.023, cerebro-spinal fluid being 1.007. The operations done include gastro-enterostomy (3), strangulated hernia (7), appendicectomy (26). In only one case where the operation was begun under spinal analgesia was it necessary to give a few drops of chloroform in stitching the abdominal wall after the operation. In no case were there any untoward symptoms after the injection. Vomiting and headache were rare, and never marked. Three operations were done on pregnant women (one of these in the seventh month), with no ill effects. S.

The Removal of Foreign Bodies from the Air and Food Passages.—Paterson (*Brit. Med. Journ.*, Feb. 8th, 1908) reports two cases showing the advantage of using the direct method with good illumination, for extracting foreign bodies from even deeply-lying sites. A young sailor aspirated a piece of nutshell into his larynx, causing severe suffocative attacks. Under chloroform, with the air passages cocainised, a Killian tube was passed through the larynx into the trachea. The tube was passed down the right bronchus, which was explored as far as the second ramification and found empty. On searching the left bronchus a mass, reddish in colour, was found blocking it just below its commencement, but its relations were difficult to make out, owing to the insufficient illumination given by a worn-out lamp. The following day the patient was again anæsthetised, the tube, with a new lamp, was passed at once down to the left bronchus, and a piece of nutshell was found lying inside the bronchus, having a small, hook-like process over the bifurcation. A Killian long forceps was passed down, the hook end was seized, and the nutshell drawn out along with the tube. The whole operation did not last more than a quarter of an hour. The second case swallowed a plum-stone, and, as a result, was quite unable to swallow any food. Using an œsophagoscope, the plum-stone was discovered a short distance above the cardiac orifice 12 inches from the teeth, lying transversely across the gullet. The plum-stone, after a little manipulation, was turned lengthwise, and grasped with the forceps and brought out along with the tube. S.

Intraligamentary Bladder.—E. Fothergill (*Jour. of Gyn.*, p. 444) observes that malformations of the bladder are by no means common. In the rare congenital anomaly known as intraligamentary bladder, the organ lies more or less between the anterior and posterior layers of the broad ligament. The utero-vesical pouch is missing, so that the bladder is not separated from the uterus by the usual fold of peritoneum; on one or both sides of the uterus the bladder spreads literally into the broad ligament. The following points have been noted about this condition: The intraligamentary bladder may be either unilateral or bilateral; if unilateral, the uterus is pushed over to the opposite side, and the relations of the tube, ovary, and round ligament are altered; a fluctuating tumour in Douglas's pouch or in the parametrium may be an intraligamentary bladder. The relations of the ureters are altered; they are, as a rule, removed further from the bladder in a lateral direction, and so further away from the vagina. The peritoneum reaches very deeply into the pelvis in front of the bladder, so that in most cases a suprapubic operation cannot be carried out without opening through the peritoneum. In all the recorded cases this condition has been discovered either post-mortem or on the operating table. G.

Painless Effusion into the Knee-Joint.—Bennet (*Hospital*, Nov. 16th, 1907) recounts a number of cases in which effusion had taken place into the knee-joint without the occurrence of any pain. He draws the following conclusions from these cases:—(1) Painless effusion into the knee-joint is primarily the result of constitutional conditions, or defective structural arrangement; (2) in the absence of increased local heat, injury need not be considered as a cause, excepting in the case of great looseness of the joint, and of tall-growing youths, when excessive exercise may be followed by transient effusion; (3) whilst the treatment in all cases without increased local heat should be directed to the avoidance of muscle waste and rectification of the laxness of the joint by massage and exercise, a permanent cure can be obtained only by the treatment of the primary constitutional defect; (4) there is no reason for suspecting tuberculosis as a cause of painless effusion, no matter how long it may exist, or how resistant it may be to treatment, unless there is persistent increase of local heat in the joint. G.

Severe Hæmorrhage from the Kidney during Nephrotomy.—G. Millar (*Amer. Jour. Surgery*, December, 1907) while performing nephrotomy encountered very severe hæmorrhage from the kidney, which all ordinary methods failed to stop, as the kidney was hypertrophied, it seemed likely that this was a compensatory hypertrophy, and that the other kidney was not acting well, under these circumstances the author could not remove the bleeding kidney. The interior of the kidney was packed with gauze, the two halves of the kidney closed upon this packing, and the entire kidney surrounded by several layers of plain gauze, wound round sufficiently tightly to stop the bleeding. The sides of the skin incision and the ureter were covered with gauze to prevent adhesions forming, the entire kidney was then plentifully covered with sterilised dressings, and fixed on the outside of the body by several strips of plaster. The fifth day after the operation all this gauze was gently removed, the kidney showed no sign of bleeding, and was allowed to slip back into its normal place. The incision was closed, and the wound remained aseptic —the after history of the case was uneventful. G.

The Treatment of Chronic Urethritis.—H. Lohnstein (*Zeits. für Urologie*, Bd. I., Heft II.). The author believes that some cases of chronic urethritis will defy all attempts of cure by the ordinary methods, for such cases he has devised an ingenious curette which is used through a urethroscope, and by means of which the entire urethra can be curetted out. This method of treatment has been particularly successful in those cases where the posterior urethra and especially the caput gallinaginis are to a great extent covered by granulation tissue. The instrument resembles an ordinary metal catheter with two lateral openings near the point, through these openings the blades of the two curettes can be protruded to the desired extent by means of a screw at the other end of the instrument. G.

The Surgical Treatment of Brain Tumour.—A. von Gehuchten (*Kundig Congress*, 1907). The surgical treatment of a brain tumour presupposes, a genuine diagnosis that a tumour exists, its localisation, and lastly, that it is accessible. In a great many cases this last condition is unfortunately wanting. The superficial and lateral portion of the brain are fairly accessible, though all tumours of the surface of the brain do not permit of accurate localisation since they do not give rise to external manifestations which are sufficiently suggestive. The percentage of cures after such operation are very small, from the author's cases and many other similar cases, only about 2 per cent. could be called permanent cures. An early operation is especially indicated in the presence of a choked disc and diminution of the visual acuity. The incision and opening in the skull must be made very wide, so that an existing tumour may not be overlooked, in case the localisation may have erred by a few centimetres. G.

Clonic Facial Hemi-Spasm Cured by Injections of Alcohol.—Noceti (*Archives d'Ophthalmologie*, Nov., 1907) publishes the notes of three cases in which the injection of 80 per cent. alcohol made at the level of the stylo-mastoid foramen brought about a cure. In Case 1, that of a woman, æt. 36, the whole side of the face was affected. The attack commenced as clonic spasm and ended as tonic. The attacks were frequent, the intervals lasting from 1 to 15 minutes. The patient had no control over the spasms, and they occurred during sleep. An injection of 1 c.c. of 80 per cent. alcohol containing 1 c. gramme of cocain, produced in about four minutes a complete facial paralysis. In half-an-hour the spasm returned. After three days the injection was repeated, followed by pain and facial paralysis again. On this occasion the paralysis lasted an hour and a half. There was no return of the spasm for 119 days, when the patient passed from observation. Case 2 was that of a man, æt. 35. The whole side of the face was affected with the platysma myoides as well. There was seldom more than 10 minutes between the attacks, and they persisted during sleep. This case got three injections, 1.5 c.c. being used for the first, and followed by facial paralysis in four minutes, which lasted 10 minutes, to be followed by the spasm as bad as ever. The second injection was made a week later, after which there was freedom from spasm for a week. The third injection of 2 c.c. was followed by paralysis for 5 days, after which there was no recurrence of spasm. Case 3 was a man, æt. 23. He had longer intervals between the attacks; two injections were made, with results similar to those experienced in the other two cases. M.

MEDICAL NEWS IN BRIEF

Proposed Sanatorium for Children.

AT the Mansion House, on February 19th, a meeting was held in aid of the sanatorium for children threatened by consumption, which it is proposed to establish at Harpenden in connection with the Children's Home and Orphanage, Bonner Road. The Lord Mayor (Alderman Sir John Bell) presided, and was accompanied by the Lady Mayoress and Mr. Alderman and Sheriff Burnett and Mr. Sheriff Wakefield, who is joint treasurer, with Mr. J. R. Barlow, of the fund. Among others present were Sir Douglas Powell (President of the Royal College of Physicians), Sir Thomas Barlow, Sir Horace B. Marshall, Mr. Helme, M.P., Mr. Ferens, M.P., the Rev. A. W. Hutton, and the Rev. Dr. Gregory (Principal of the Institution).

The Lord Mayor expressed his sympathy with the movement, and dwelt on the importance of taking steps to stamp out consumption among the young.

Dr. Gregory, in an explanatory statement, said that it was not intended to build a general home for consumptive children. In the first place, they intended to deal only with those members of their own community who were in need of special treatment. They must raise 10,000 guineas as an establishment fund, towards which 4,400 guineas had been either promised or received. Mr. Sheriff Wakefield and Mr. Barlow had each given 500 guineas, and an anonymous friend of the former had contributed a like amount.

Sir Douglas Powell said that there was not much difficulty in supporting the appeal of such an institution as this, which had been established for well-nigh 40 years, on behalf of its work for little children. He understood that in its several branches it now had the charge of 2,000 children who, it should be borne in mind, came from the darkest places of the earth. For the past 50 years the mortality among those born in England and Wales had been between one-sixth and one-seventh, so that about 15 per cent. of them died in the first year of life. As on the battlefield one death meant many wounded, so in the campaign of life the sacrifice of 15 per cent. of those born meant the disablement of a very much larger percentage for the struggle of life. He gave his most cordial support to the scheme.

Sir Thomas Barlow spoke on the differences between tuberculosis as it occurred in children and as we were more familiar with it in adults. In the latter it took the form of consumption of the lungs, but with children that was not usually the case. If the young suffered from tuberculosis, it was very often locally—from affections of the glands and bones. Hitherto the special claims of children in respect to this disease had hardly been placed before the British people. In the children's home they had the means of dealing with the sufferers in the early stages, and he believed that the proposed sanatorium would permit of real, thorough work being done, and that the result would be to transform poor, delicate children into healthy men and women.

Mr. Sheriff Wakefield said that they were not starting out on an expensive enterprise, in which money was to be spent on elaborate buildings. They aimed at giving the little children a chance in life.

A collection was taken for the fund.

Royal Medical Benevolent Fund Society of Ireland.

A REGULAR quarterly meeting of the Central Committee was held on Wednesday last at the Royal College of Surgeons.

The Secretary reported the death of Dr. Conolly Norman, a member of the Central Committee. The following resolution was passed unanimously:—

"Resolved: That at this, the first meeting of the Central Committee held since the lamented death of Dr. Conolly Norman, the members of the Committee desire to record their sorrow at the sad event which has deprived the Royal Medical Benevolent Fund Society of Ireland of a staunch friend and annual subscriber, and the members of the Committee of a genial colleague. They would take this opportunity of conveying to Mrs. Norman an expression of their sympathy with her in the grievous and sudden bereavement which has befallen her."

The Secretary stated that a donation of £25 had been received from Dr. Atthill. Three urgent applications for aid were considered, and grants amounting to £16 were made.

The meeting then adjourned.

Glasgow Midwife in Trouble.

BEFORE Sheriff Mackenzie in Glasgow on February 21st, a middle-aged woman, Mary Hall or Russell, midwife, was charged with having omitted to give notice that she had received four children on consideration of sums of money. Accused while on bail attempted to leave the country, and was arrested on board an Atlantic liner at Southampton. The prosecution was under the Infant Life Protection Act. She pleaded not guilty, and four young women, the mothers of the children, gave evidence of having paid accused, in three cases £7 and in one £5, on the understanding that she was to obtain a home for the infants. The Sheriff found the charges proved, and ordered accused to forfeit the money she had received, the alternative being in each case imprisonment for 21 days. In a second charge, Mrs. Russell pleaded guilty to having failed to notify the Procurator-Fiscal of the death of two children. The Sheriff considered the observation of this section of the Act very important, but as a doctor was actually in attendance on the children, and in a position to give a certificate, that made the case much less serious. He imposed a penalty of £10, with the alternative of two months' imprisonment.

The Battle Against Tuberculosis.

AT a meeting of the Liverpool Health Committee, held on February 27th, Mr. Lyle Rathbone (deputy-chairman) presiding, Mr. Parkinson, in view of the alarming remarks recently made by Dr. Nathan Raw, asked was it not a fact that consumption had decreased by 50 per cent. in Liverpool during the past 30 years. Dr. Hope, the Medical Officer of Health, replied that consumption was declining very rapidly. Of course, the aim and object of the Health Committee was to enable people in their own homes to avoid the conditions which led to consumption. That, in fact, had been the policy of the committee for a great number of years, and it had received a very marked reward in this city. Other towns were, of course, doing the same thing, and, happily, with the same results, so that throughout Great Britain, in great towns and in small towns, there was a steady and continuous diminution in the number of deaths from phthisis and the various forms of tuberculosis. It was a great mistake to think that the disease was not showing the same marked decline as other forms of communicable diseases were showing.

Sickness in Mid Cheshire.

Another Northwich school, Danebridge Infants', was closed on February 18th owing to the widespread epidemic of measles in Mid-Cheshire. Two Northwich National and the three Northwich Council schools are still closed, and elementary education in the town is in a large measure at a standstill. Several other schools which have resumed work recently had to undergo periods of closure from the same cause.

At the meeting of the Saddleworth District Council recently, Dr. Ramsden, the Medical Officer of Health, reported that he had never in his experience known so much sickness as during the past month. Almost every family in the district had been affected, the chief ailment being influenza.

Death from Lock-jaw.

Mr. T. Foster Barham held an inquest at Taunton on February 19th on Wm. Hutchings, aged 56, an engine driver, of Combe St. Nicholas, Chard. On February 5th deceased was working at Donyatt, near Ilminster, when the needle of a threshing machine he was attending went through his right hand. As tetanus began to show itself, the doctor injected an antitetanic serum, but as the wound did not improve, the man was sent to the Taunton and Somerset Hospital. Here the injection treatment was continued, but without success, and the man died on the 16th. A verdict of "Accidental death" was returned.

Claim for Medical Attendance.

At St. Helens County Court, on February 19th, Dr. J. S. Fox sued Mrs. Kiernan, a widow, of Robins Lane, for £31 16s. for medical assistance. Mr. Greaves Lord (instructed by Messrs. Brewis), for plaintiff, said Mrs. Kiernan's husband was an insurance agent, and when he died there were considerable assets, the chief being an equity for £560. Efforts had been made to try and get defendant to administer, but there had been great delay, and they had brought this action against her as administratrix *de son tort*. Mr. Rigby Swift, on behalf of the respondent, read correspondence which had passed between Messrs. Brewis and Messrs. Oppenheim, who represented her, and said the action was brought in the wrong form. There was a will, and defendant had partially administered, and they ought to have waited until the administration was complete. Mr. Greaves Lord said they had not been precipitate because during the whole time a suggestion had been made that Mrs. Kiernan was too unwell, but they believed, as a matter of fact, that the thing had been delayed on purpose His Honour Judge Shand said Mr. Swift was entitled to have the action dismissed, but it could be amended. Mr. Swift said the assets were £564 9s., of which £4 9s. was in cash and £560 was the value of an equity, but the mortgagee was in possession and was receiving the rents. After some discussion, his Honour dismissed the action, and gave costs in favour of Mrs. Kiernan, but amended the application and gave judgment against her, as executrix, for £31 16s.

The Journal of the Royal Medical Society.

The appearance of the monthly Journal of the Proceedings of the Royal Society of Medicine marks a noteworthy addition to medical periodical literature. Issued in a green paper cover, small quarto size, it has a solid if somewhat sombre exterior that carries with it an indefinable air of authority. The contributions in the first few numbers are excellent, and if the future standard be maintained at an equal level, the new journal will speedily attain the position of a classic. That is quite as it should be, for hitherto the success of the Royal Society of Medicine has been phenomenal. Although its birth was accomplished under a cloud of doubts and difficulties, it has speedily justified its claims to existence by attaining both popularity and scientific distinction within an incredibly short space of time. It is to be hoped that some of the exclusive features that have hitherto hampered the work of scientific societies in this country will never be allowed to darken the counsels of the new Society. Meanwhile, we extend to our contemporary a hearty welcome, and at the same time venture to express a hope that the promise of its youth may be borne out by many years of prosperity and usefulness in the service of the great and humane profession of which it is the youngest handmaid.

New Tuberculin Preparations.

Messrs. Allen and Hanburys, Limited, have brought to our notice their numerous preparations of tuberculin, human and bovine.

They send specimens of the curative New Tuberculin T.R. in sterile azoules ready for injection; doses of New Tuberculin-Bacillus emulsion, and of Old Tuberculin for diagnostic use are similarly prepared. The Old Tuberculin, it is hardly necessary to remind readers, is chiefly used as a diagnostic agent by hypodermic injection. If tuberculosis be present, local and general reaction results.

They also submit a specimen of Tuberculin for ophthalmic use as a diagnostic according to the method of Calmette. This contains 0.5 per cent. of the solid matter of Old Tuberculin; a similar solution containing 0.1 per cent. can also be supplied. We have tried the preparation in several cases, and have found it satisfactory.

These preparations are for the most part put up in an extremely convenient form in azoules, containing any ordinary dose. Some of them are more conveniently sold in powdered or liquid form.

Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society, was held at 6, Catherine Street, Strand, London, W.C., on February 21st.

There were present Dr. de Havilland-Hall (in the chair), Dr. F. J. Allan, Dr. Fredk. S. Palmer, Dr. J. Brindley James, Dr. H. A. Sansom, Mr. F. S. Edwards, and Dr. J. B. Ball.

The accounts presented showed a large increase in the amount of sickness pay, caused by the present epidemic of influenza. As on previous occasions a large number of medical men seem to be suffering from this troublesome malady, but the claims are generally of short duration, and make but a small inroad on the large reserves of the Society.

The number of members permanently incapacitated and drawing sick pay, usually one hundred guineas a year, is still growing; but special and full reserves have been made for them at each valuation of the Society's business.

Prospectuses and all further particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The movement to commemorate in Glasgow the late Dr. James Finlayson by the establishment of a lectureship took practical shape on February 26th, when a lecture was given in the Hall of the Faculty of Physicians and Surgeons by Dr. Norman Moore, of St. Bartholomew's Hospital, London, on "Schola Salernitana." The lecture is to form one of a series on medical history.

No further cases of small-pox have been discovered on the steamer *Dalbeattie*, from Bilbao, now at Rothesay Dock, Clydebank. The members of the crew were all vaccinated, as well as some dock labourers, and even a policeman, with whom the victim, a Norwegian, is supposed to have come in contact.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

A NEW VERSION.

Examiner: "If a man fell into an empty well, forty feet deep, and struck his head against the bucket at the bottom, what would be your course if summoned as a surgeon?"

Student: "My advice would be to let the man lie where he was, and suggest that the well should be filled up."

Dr. McWalter and Mr. J. A. Walker.—Letters crowded out at press.

H. H.—We are glad to say that the military authorities have removed the prohibition against soldiers' wives having recourse to civil medical practitioners for themselves or for their children. There was a great want of common-sense about this last rule, seeing that many military medical officers have little experience of family practice, while it frequently happens that many of the young married women in a unit belong to families in the locality, who have for years been attended by their own family doctor. The incongruity of the order has presented itself to the Army Council, who have taken steps to remove the restriction, and to permit families to seek medical treatment where their preference lies.

Dr. **Blair Bell**'s letter came to hand as we were "at press"; we hope to have space for it in our next.

Dr. J. K. M. is thanked for his communication, of which a note has been made.

Mr. **J. S. Watson.**—Yes, but only in India and Ceylon, so far as we are aware.

Meetings of the Societies, Lectures, &c.

Wednesday, March 4th.

Royal College of Surgeons of England.—5 p.m.: Prof. F. C. Shrubsall: The Physical Anthropology of the Pigmy and Negro Races of Africa. (Hunterian Lectures.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Prof. W. E. Dixon: The Action of Tobacco Smoke.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m. Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

Thursday, March 5th.

Throat Hospital (Golden Square, W.).—5.30 p.m.: Lecture:—Mr. Faulder: Diseases of the Perceptive Mechanism—Chronic.

North-East London Clinical Society (Prince of Wales's General Hospital, Tottenham, N.).—4.15 p.m.: Clinical Cases.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—Discussion on the Treatment of Pneumonia (opened by Dr. S. West).

Child Study Society, London (Parkes Museum, Margaret Street, W.).—8 p.m.: Mr. W. T. Elliott: The Education (Administrative Provisions) Act in Relation to the Inspection and Treatment of the Teeth.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture:—Dr. D. Grant: Acute Inflammation of the Middle Ear.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Throat Operations (Mr. Carson).

Great Northern Central Hospital (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

St. John's Hospital for Diseases of the Skin (Leicester Square, W.C.).— 6 p.m.: Lecture:—Dr. M. Dockrell: Fungous Diseases of the Skin: I., Tinea Circinata; II., Tinea Imbricata; III., Tinea Versicolor; IV., Erythrasma; V., Actinomycosis; VI., Madura Foot.

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Hutchison: Intestinal Worms and their Treatment.

Friday, March 6th.

Royal Society of Medicine (Laryngological Section) (20, Hanover Square, W.).—5 p.m.: Dr. G. K. Grimmer, Dr. E. B. Waggett, M. A. R. Tweedy, Dr. H. B. Robinson, and Mr. F. J. Steward: Cases and Specimens.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8.30 p.m.: Dr. Wylie: Foul Breath, its Causes and Treatment; Mr. Bowen: Pneumococcal Otitis Media.

Society of Anæsthetists (20, Hanover Square, W.).—8.30 p.m.: Mr. H P Dean: Spinal Anæsthesia. Followed by the Annual Meeting.

Royal College of Surgeons of England.—5 p.m.: Prof. F. C. Shrubsall: The Physical Anthropology of the Pigmy and Negro Races of Africa. (Hunterian Lectures.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Dr. D. Grant: Clinique (Ear).

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Great Northern Central Hospital (Holloway Road, N.).—3.30 p.m.: Lecture:—Mr. V. W. Low: The Diagnosis and Treatment of certain Fractures.

Saturday, March 7th.

Royal Society of Medicine (Otological Section) (20, Hanover Square, W.).—10 a.m.: Mr. S. Scott, Mr. C. E. West, Mr. H. H. B. Cunningham, Dr. A. Bronner, Mr. M. Yearsley, and Dr. D. R. Paterson: Cases and Specimens. Mr. S. Scott and Mr. C. E. West: The Operative Surgery of the Labyrinth.

Appointments.

Breakell, Frederic James, L.R.C.P., and S.Edin., L.F.P.S. Glasgow, Second Assistant Medical Officer to the Suffolk District Asylum.

Elder, G. T. D., M.R.C.S., L.R.C.P.Lond., Surgeon to the Mansfield District Hospital.

Elliott, William Harold Arthur, M.B., B.S.Lond., L.S.A., Demonstrator of Anatomy at University College, Bristol.

Fortescue-Brickdale, John Matthew, M.D., B.Ch.Oxon., Director of the Public Health Laboratory, University College, Bristol.

Goulden, Charles Bernard, M.B., B.C. Cantab., F.R.C.S., Demonstrator of Anatomy at University College, Bristol.

McVittie, John, M.B., Ch.B. Glasg., Medical Officer and Public Vaccinator for the Parish of Dailly, Ayrshire.

Rhys, Owen L., M.B., B.Ch.Edin., Medical Officer in Charge of the Electrical Department, Cardiff Infirmary.

Thomson, H. Campbell, M.D.Lond., F.R.C.P.Lond., Dean of the Medical School of the Middlesex Hospital.

Vacancies.

Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary, £150 per annum, and all found except liquors. Applications to the Medical Superintendent.

The Royal Albert Asylum, Lancaster.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, apartments, and washing. Applications, Archibald R. Douglas, Medical Superintendent.

London Fever Hospital, Liverpool Road, N.—Assistant to the Resident Medical Officer. Salary, £120 per annum, with residence and board. Applications to the Secretary.

St. Mary's Hospital Medical School, Paddington, W.—Demonstrator of Physiology. Salary, £150 per annum. Applications to the Secretary.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary, £150 per annum, together with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Hampshire County Council.—County Medical Officer of Health. Salary, £700 net. Applications to H. Barber, Clerk of the Council, The Castle, Winchester.

Lanark County Council.—Bacteriologist for Public Health Laboratory Salary, £250 per annum. Applications to the County Medical Officer, Hamilton.

Pontypridd Education Committee.—Medical Officer to the Education Committee. Salary, £200 per annum. Applications to D. Milton Jones, Secretary, Education Offices, Pontypridd.

Births.

Coldstream.—On Feb. 28th, at Belford, Northumberland, the wife of George Probyn Coldstream, M.B., C.M., of a son.

Shaw.—On Feb. 28th, at 41 King Street, Gt. Yarmouth, the wife of Raymond Henry Shaw, MS., M.B., of a son.

Young.—On Feb. 27th, at Stoney Stanton, Leicestershire, Helen, the wife of Graham Pallister Young, M.B., B.S.Lond., M.R.C.S., L.R.C.P., of a daughter (Elizabeth).

Marriages.

Little—Leslie.—On Feb. 29th, at St. George's, Hanover Square, London, Charles James Colebrooke Little, Lieut. R.N., son of Louis S. Little, F.R.C.S., B.A., of 31, Grosvenor Street, London, and Whitehill, Bletchingley, to Rothes Beatrix, youngest daughter of the late Colonel Sir C. H. Leslie, Bart., C.B., and Lady Leslie, of Rosemoor, Ipplepen, S. Devon.

Deaths.

Biss.—On Feb. 27th, at Hampstead, Janet, wife of Cecil Yates Biss, M.D., F.R.C.P., aged 57.

Cotterill.—On Feb. 27th, at Edinburgh, Mary, the beloved wife of J. M. Cotterill, F.R.C.S.

Ellett.—On Feb. 28th, at the Metropolitan Hospital, London, George Grigson Ellett, M.D., aged 31.

Hallam.—On Feb. 22nd, at Monte, Grand Canary, William Henry Hallam, L.R.C.P.Edin., M.R.C.S.Eng., D.P.H. R.C.P.I., of Fairview, Newquay, Cornwall, formerly Medical Officer of Health of Newcastle, Staffordshire

Smith.—On Feb. 24th, at Arnside, Carnforth, Fanny Eliza Smith, eldest daughter of the late John Whitaker Smith, M.R.C.S., formerly of Finsbury Square, aged 79.

THE LANCET,

Feb. 8th, 1908,

says :

"These foods in general show, according to analysis, a high nutritive value in regard to all classes of material which minister to the needs of the body. The 'Proteid Food,' for example, contained as much as 32 per cent. of proteins which are more or less in a soluble state, and the mineral salts amounted to 7·10 per cent. Its addition to other foods is, of course, calculated to raise their nutritive value. The food for infants contains a well-balanced proportion of proteins, fats, carbohydrates, and mineral matter. It is a particularly satisfactory fact that this food showed no deficiency in regard to fat, the amount being 21 per cent. The proteins amounted to 22·75 per cent. and the mineral matter to 4·50 per cent. We have also examined cocoa, biscuits, and soup tablets, which all evidenced a rich proportion of nourishing constituents."

EUSTACE MILES

PROTEID FOOD,
COCOA, BISCUITS,
INFANTS' FOOD,
AND SOUP TABLETS

are used largely in Hospitals, Nursing Homes, &c., and are recommended by . . leading Medical Men . .

Samples Free by Post to the Profession.

E. M. PROTEID FOODS, 40, Chandos Street,
Charing Cross, London, W.C.

The published statements of prominent surgeons of all countries show that

ARGYROL

(Silver Vitellin)

is the best silver salt, and that no known agent can compare with it in eradicating gonococcal and other infections, speedily and without discomfort to the patient.

Argyrol is used in 10 per cent. solution as injection in gonorrhœa every 3 hours; in 25 per cent. solution as instillation (diseases of eye) every half hour or hour, and in 25 per cent. solution as local application (throat, vagina, etc.) once daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

One unique effect of

OVOFERRIN

(Iron Vitellin)

is its property of improving the patient's general nutrition in a very striking manner.

Literature on Ovoferrin by recognized authorities in medicine in America and Europe, show that it is a hæmatinic and general tonic of very unusual value.

Ovoferrin is furnished by chemists, on prescription, in twelve-ounce bottles. The dosage is one tablespoonful in wine-glass of water or milk three times daily.

Produced by

BARNES & HILLE,

32 Snow Hill, LONDON, E.C.

TRADE 'ALAXA' MARK

AN AROMATIC LIQUEUR
OF CASCARA SAGRADA

'ALAXA' presents a *fluid* cascara of the same high therapeutic standard as 'TABLOID' CASCARA.

'ALAXA' is the result of specialised study and research, and embodies the nearest approach to the isolation of the pure active principle of Cascara Sagrada yet obtained.

Its laxative action is supplemented by stomachic and carminative constituents.

'ALAXA' is so palatable that it may be given as an aperient *apéritif* or a laxative *liqueur*.

Careful clinical tests have confirmed its certainty of action and its superiority to bitterless extracts treated with excess of alkali, and rendered comparatively inactive in consequence.

ALAXA
An Aromatic Liqueur of Cascara Sagrada
ALAXA
An Aromatic Liqueur of Cascara Sagrada

One fluid drachm contains the equivalent of twenty-four minims of Liquid Extract of Cascara Sagrada, B.P.

SPECIAL NOTE

Cordials and Elixirs are so loaded with syrup and flavouring matter that a large dose is required.

The full dose of 'ALAXA' is 2 fluid drachms.

Supplied to the medical profession, in 4-oz. bottles, at 2/- per bottle

ANALGESIC BALM
Menthol, methyl salicylate and lanoline. Indicated in frontal neuralgia.

ANTI-CATARRHAL

ADRENALIN INHALANT

ADRENALIN CHLORIDE SOLUTION

CHLORETONE INHALANT

These are conveniently administered by the "Glaseptic" Nebuliser.

CORYZA
T.T. No. 722

Camphor	1/2 gr.
Quinine Sulphate ...	1/2 gr.
Morphine Sulphate ...	1/64 gr.
Atropine Sulphate ...	1/2000 gr.

ANTISPASMODICS

Indicated in excessive cough and in intestinal pain.

CHLOR-ANODYNE
Each fluid ounce contains:

Morph. Hydrochlor. ...	2 7/8 gr.
Fl. Cannabis Indica ...	46 min.
Dil. Hydrocyanic Acid	9 min.
Chloroform	46 min.
Oil of Peppermint ...	1 1/2 min.
Tinct. Capsicum ...	1 1/2 min.

BROMIDE COMPOUND
Elixir No. 127.
Each fluid ounce contains:

Chloral	120 grs.
Potassium Bromide ...	120 grs.
Ext. Cannabis Indica	1 gr.
Ext. Hyoscyamus ...	1 gr.

LAXATIVES.

GRAN. EFF. SALINE LAXATIVE
Each drachm contains:

Sodium Phosphate ...	20 grs.
Magnesium Sulphate...	25 grs.
Sodium Sulphate ...	10 grs.

CASCARA EVACUANT
The most efficient palatable preparation of Cascara Sagrada.

ALOIN AND PHENOLPHTHALEIN CO. Pill No. 974

Aloin	1/4 gr.
Phenolphthalein ...	1/2 gr.
Strychnine	1/60 gr.
Extr. Belladonna Leaves	1/12 gr.
Powd. Ipecac.... ...	1/16 gr.

RECUPERATIVES.

HEMATIC HYPOPHOSPHITES
Each fluid ounce contains:

Potassium Hypophosphite,	1 1/2 grs.
Manganese Hypophosphite,	1 gr.
Strychnine Hypophosphite,	1/8 gr.
Iron Hypophosphite,	1 1/4 grs.
Calcium Hypophosphite,	1 gr.
Quinine Hypophosphite.	7/16 gr.

HYPOPHOSPHITES AND QUININE COMPOUND
C.T. No. 27.

Quinine Hypophosphite,	1 gr.
Ferric Hypophosphite,	1/2 gr.
Calcium Hypophosphite,	1/2 gr.
Sodium Hypophosphite,	1/4 gr.
Potassium Hypophosphite,	1/4 gr.
Manganese Hypophosphite,	1/4 gr.

GLYCEROPHOSPHATES WITH IRON, QUININE AND STRYCHNINE
Elixir No. 145.
Each fluid ounce contains:

Calcium Glycerophosphate,	8 grs.
Sodium Glycerophosphate,	16 grs.
Iron Glycerophosphate,	1 1/2 grs.
Manganese Glycerophosph.,	1 gr.
Quinine Glycerophosphate,	1/2 gr.
Strychnine Glycerophosphate.	1/16 gr.

VOL. CXXXVI. WEDNESDAY, MARCH 11, 1908. No. 11.

NOTES AND COMMENTS.

Medical Examination and Workmen's Compensation.

MANY important and difficult legal points affecting medical men are constantly arising under the Workmen's Compensation Act, and it is unfortunate that, so far, there have been but few authoritative decisions with regard to them. Last week, at Longton County Court, in Staffordshire, there was an interesting argument, in which two questions were at issue before the Judge. One of these was whether a workman, having submitted to medical examination, and having had his payments stopped in consequence, can be compelled to undergo a further examination with a view to obviating proceedings. The other was whether a workman can claim that his medical man shall be present at the examination; while incidentally it was suggested by counsel that a workman cannot be compelled to attend for examination anywhere but at his own house, and that therefore the employer's doctor is bound to visit him there. The Judge supported the contention that a workman cannot be compelled to submit to medical examination when his payments have been stopped, because the rules under the Act only provide for examination while the payments continue. He also, on the ground of custom, upheld the argument that it is proper that the workman's own doctor should be present at a statutory examination, and in this decision he will certainly be supported by medical opinion.

Representation at Examination.

WITH regard to the question whether an employer can claim an examination after payments have ceased, we have only to say that it is one of the legal flaws which the best-drawn Acts fail to obviate, but the point of the representation of workmen at an examination is a much more difficult one. So long as he is represented by a qualified medical man, no question should arise except one of practical convenience, but in many cases, whether by reason of expense or other factor, no medical man is employed, and the solicitor for the plaintiff insists on being present or having the examination conducted at his office. As a matter of professional dignity, we cannot agree that a solicitor should be present during the physical examination, but we think he has a right to hear all questions put relative to the injury in order that he may advise his client not to answer any question which is not medical in its bearing. We think that medical men, when acting for employers, should recognise that it is not their business to ascertain how an accident happened, but should confine their attention to deciding whether the alleged accident could have produced the condition found on examination, and how long the disability is likely to last. By restricting themselves entirely to the medical aspects of the case, they have not only the right, but the obligation to ask every necessary question as to the actual nature of the accident, for it is their duty to advise the employer on these points.

History and Place.

Now, as the history is the essential part of a medical examination, the further point arises whether a workman who refuses to answer questions relative to his history can be said to "obstruct" an examination within the meaning of the Act. For, if he refuses to submit to examination or wilfully obstruct it, no compensation is payable till a proper examination has been submitted to. The point has not, we believe, been decided, but it frequently arises through solicitors advising their clients not to answer any question put by the doctor, but merely to submit themselves to physical examination. Sooner or later it must be settled, for it is obvious to medical men that no "examination" which excludes the previous history is a proper examination, if indeed it can be called an examination at all. Further, we feel that the place of examination must be sooner or later settled. If a man is confined to bed or the house, naturally he cannot be expected to come to the doctor's house, but in any other case it is patently in the interest of justice that he should be examined in a proper consulting-room where all necessary light and apparatus are provided. Any employer insisting on examination taking place at the doctor's residence would have a very strong case if the matter were insisted on in court, especially if he offered the workman his expenses.

Cocaine and Dentistry.

ISIDOR ZEIFERT, the Soho "dentist," was acquitted at the Old Bailey last week of the crime of manslaughter, which the coroner's jury found against him when the death of Jane Farvish was lately inquired into. We are not concerned to say whether the offence of administering half or a third of a grain of cocaine to a person suffering from heart disease, of which fact the administrator was ignorant, is in itself manslaughter, because the jury found otherwise. But we do say that it is perfectly monstrous that an unregistered practitioner should have free play to administer these dangerous doses to his Majesty's subjects under the full protection of the law. Indeed, the community which complacently suffers such doings can only be regarded as one in a state of semi-barbarism. As the victims of the system are all poor people, their deaths excite but the most languid interest among our legislators, and we really think that the Labour Party who hold themselves out to represent the most helpless section of Society, might, nay, should, probe the shocking state of unqualified dental practice to the bottom, and set themselves to work to obtain for the less wealthy classes the same protection that the better-to-do ones enjoy. In working-class districts it is often impossible to find a qualified dental surgeon, and the labouring classes for their dental troubles are forced to go to the ignorant, untrained, and unscrupulous mechanicians who, having served an apprenticeship in the handicraft of making artificial teeth, set up as dentists, administer anæsthetics, and trifle with human life and health.

A Daniel on the Bench.

IF anyone wishes to realise the hopelessness of conveying to the laity the iniquity of this practice, he has only to read the summing-up and incidental remarks of Mr. Justice Bucknill in the Zeifert case. The defendant alleged that he had taken the "primary" degree of Bachelor of Medicine in Russia, but left that country before finally qualifying, owing to political matters. The statement was unsupported, but even admitting it to the full, we maintain it is patent evidence that Zeifert is not qualified to examine the hearts of patients who come to him, and not qualified to administer anæsthetics. Yet the learned occupant of the Bench described him as a "Russian gentleman of good education who had come here because he preferred to live in this country where he could practice his profession in safety without regard to his political views"! We wonder what his lordship would have said if a well-educated Russian gentleman who was not even called to the bar in his own country, had appeared before him to defend a prisoner charged with stealing a twopenny loaf? In one case the prisoner's liberty for a month might be involved; in the other the matter is one of life and death. Mr. Justice Bucknill, in fact, treated the prisoner throughout as if he had been a qualified man, and in assessing the culpability, took no account of the fact that the prisoner held himself out to perform certain duties which he is not capable of performing. Naturally he was found "not guilty" by the jury, and on his being discharged, the Judge addressed him, saying that he agreed with the verdict. "Let me remind you," he added, "so that you may be wiser in the future—take my advice, that with the knowledge that we now have of cocaine, and that you have, it will be extremely unwise of you if you ever administer it without first ascertaining the condition of the patient's heart." Whilst such wisdom is to be found on the Bench, how can we expect any restriction of improper practice?

A Pure Milk Bill.

MR. BURNS has made the definite and most satisfactory announcement we have seen for a long time, namely, that he intends to bring in this session a Bill dealing with the milk supply of the whole country. We cannot use sufficiently warm terms in which to congratulate the right honourable gentleman, subject to two provisos, namely, that the Bill shall be bold and comprehensive, and that it shall be meant to pass. There is, in our opinion, no factor of more vital importance to the public health, and especially to children's health, than a pure milk supply. We do not under-estimate the difficulties in the way of securing it. The agricultural "interest" is very strong in the House of Commons, at least as strong as the liquor interest, and Mr. Burns does not need us to tell him the enormous amount of opposition he will meet with from the Members for rural constituencies. Then, too, there are the railway companies, who will fight any additional burdens and restrictions, and commercial men generally who will oppose anything that interferes with trade. We think the time has long gone by for dallying with the question. The "smoking hetacombs of babes" which annually disfigure the vital statistics of every large town may not all be slaughtered by foul milk, but it is certain that a very large proportion of them are, and it is equally sure that nothing but a vigorous effort will bring the responsible parties to a sense of their duty in the matter. Let Mr. Burns grasp the nettle, and he will have every hygienist in the tountry at his back.

LEADING ARTICLES.

QUACKERY IN AUSTRALIA.—No. II.

THE storehouse of data on the subject of secret drugs, cures, and food contained in the first Report of the Australian Royal Commission is bewildering in its vastness. Here we find for the first time in history the protean aspect of a corroding social evil displayed to the public gaze. It is impossible to glance through these pages without being convinced that the essence of the enormous traffic under investigation lies in secrecy, deception, fraud, and crime. A general notion of the impression made upon the Commonwealth Commissioners may be formed from the following passage at the head of their "conclusions": "Quackery, it has been shown, affects the domain of therapeutics, hygiene, and nutrition. It demands secrecy and deception as indispensable conditions, where the racial interests demand truth and candour. And, again, by inversion, it invades, publishes, and profanes that which the consensus of sane mankind from time immemorial has made secret and sacred—the sexual privacies of women and the functions upon which depend the perpetuation of the race. It has also been shown herein, with such reserve as decency requires—when none at all is exhibited by the quacks themselves or exacted of them by our laws—that the natural phenomena of healthy puberty are utilised with Satanic ingenuity by these quacks and their collaborators in the Press to frighten young men and young women into seeking their help. That it is not casual or unusual for many young persons to correspond with the gilded miscreants has been shown by the fact that one concern—the J. W. Kidd Company (pars. 946-950)—offers for sale 300,000 letters from their unhappy "patients"; and another—a broker—offers 2,000,000 assorted letters from various quack syndicates. One of these concerns has over 7,000,000 letters (*vide* par. 965). How large is the traffic can be gauged from the cost of their advertisements in daily papers, which halve the spoils with the brigands—only that with highwaymen we do not read of quite such ruthless and ruinous betrayal. These letters thus offered in the market—again by the help of the Press—were written, as Dr. Stanley Hall ('Adolescence') informs us, from actual purchase and inspection, with the "youths' heart-blood." This extremely outspoken and emphatic opinion, be it noted, covers only a small portion of the ground. If similar practices are being carried on in the United Kingdom—and we know that such is the case—then the appointment of a Royal Commission is urgently required within our own gates. As a matter of fact, cases of wholesale blackmailing of luckless women have within recent years been divulged in the police courts. But the range of quackery is well-nigh illimitable, and wherever we turn to analyse its pretensions or its methods we are constantly faced with the same underlying trickery, cruelty, and fraud. The probability of a scandalous revelation is no argument against the need of authoritative British inquiry. Nay, rather, it is a strong reason why that course should be adopted forthwith without a moment's delay, viewed in the light of the damning evidence set forth in the Australian Blue Book. Turning to recommendations, we find the first contains the crucial advice that every preparation for the prevention, alleviation, or cure of human ailments should have attached to it its formula, legibly printed. Further, it is advised that no declaration of merits or advertisement of any kind be permitted on labels or wrappers; that no advertisement of any proprietary or secret cure be permitted in newspapers or elsewhere; that such advertisements shall not be sent by post; that there be compulsory registration of all proprietary names, and that the registrar shall be empowered to judge whether the formula represents a drug or compound preparation that may safely be entrusted to inexperienced and uninformed persons for the purpose of self-treatment. Another most practical and radical recommendation is that every imported article should be subject to the same control as would be exercised in the country of origin. Possibly our great Colony of Australia will be beforehand in adopting these principles. It is certain that no civilised people will indefinitely permit themselves to be exploited by the haphazard administration of drugs that can be used with safety in the treatment of human maladies only under skilled scientific supervision. The General Medical Council recently agreed to a wretchedly inadequate inquiry into the abuses of quackery. It is to be hoped that some of the members of that body, on both the Conservative and the Progressive sides, will peruse the Australian Blue Book we have here shortly reviewed. It is a human document of the very highest importance, and registers the first step of a crusade that is demanded in the interest of all sane ideals regarding the moral and material progress of mankind.

QUALIFICATION AND TENURE OF PUBLIC HEALTH OFFICERS.

A good deal of attention in public health circles will naturally be attracted by the printing of Sir Walter Foster's "Bill to Amend the Law Relating to the Qualification and Tenure of Office of Medical Officers of Health, and for other purposes." It is backed by Sir John Tuke, Sir Francis Powell, and Mr. Cooper, and is prefixed by the following memorandum:—

> "The main objects of this Bill are to ensure that none but those properly qualified shall be appointed as medical officers of health or sanitary inspectors, and to give all such officers and inspectors similar security in their tenure of office to that enjoyed by Poor-law medical officers and metropolitan medical officers of health. As the law stands, no qualification is required for a sanitary inspector except in London, and as a general rule a medical officer of health or sanitary inspector is appointed from year to year only, and thus has no true security of tenure. Poor-law medical officers and metropolitan officers of health are not appointed for limited periods only, and are removable only by, or with the consent of, the Local Government Board. Except in London, urban sanitary authorities have no legal power to appoint more than one sanitary inspector. It is desired to extend the metropolitan powers to all urban sanitary districts. In London the sanitary inspector is so called by law; but outside London the law names him 'inspector of nuisances.' It is proposed that the London name shall be universally used."

With regard to the security of tenure of office of the medical officer of health, the approval of the medical profession will be unanimous. There can be little doubt that the holders of such posts are prevented from discharging their duties in an efficient and independent manner because of the annual re-election they have to face by an authority which is largely composed of property-owners and tradesmen. If this piece of legislation be brought about it must necessarily effect a silent, though none the less a sweeping, reform in the public health administration of the nation generally. Something of the same line of argument applies to the sanitary officer, although to a much less extent. In our opinion, his tenure of office might well be settled, given certain safeguards by way of appeal, to the discretion of the medical officer of health to whom he is subordinate. As regards proper qualification, there will be, in all probability, a general consensus of opinion as to the desirability of such a condition in the case of the medical officer. When we turn to the sanitary inspectors, we find ourselves faced with a similar set of circumstances. In the first place, what is to be accepted as the qualifying board, and who is to fix the standards of examination for proficiency of knowledge? It would surely be only reasonable to demand that the certificate or diploma should be under official recognition. At the same time it may perhaps be not altogether impertinent to remark that there threaten to be too many examination boards for sanitary inspectors, and that an authoritative supervising body is needed. So far as the projected Bill proposes to improve sanitary administration in the rural districts of the United Kingdom, it may be heartily welcomed. The backward conditions of many such authorities as regards water supply, infectious disease accommodation, disinfection, and other primary essentials of health, are simply deplorable. In the vigorous hands of Sir Walter Foster the country may look forward to a substantial advance in a branch of social economy which has from the first been pre-eminently British, but which now threatens to lag behind other nations in the equality of its general standards. A village in the Black Country should be no less sanitary, *mutatis mutandis*, than a fashionable London suburb. Yet in London itself there is ample need for reform, as evidenced by the disproportion in the infantile mortality of its wealthy and its poverty-stricken districts. Meanwhile, Sir Walter Foster's Bill may be welcomed as a step in the right direction.

CURRENT TOPICS.

The New Poisons and Pharmacy Bill.

The new Poisons and Pharmacy Bill, introduced by Lord Crewe, has been read a second time and referred to a Joint Committee of both Houses of Parliament. It contains some salutary provisions, notably, that when a chemist carries on business in more than one shop, there shall always be a qualified chemist in charge. A sensible proposal is that certain poisonous substances used for agricultural and horticultural purposes, such as sheep-dips, may, in case of need, be sold by dealers who are not chemists. This step, while expedient, of course does not do away with the necessity for proper safeguards. One of the most important and controversial questions affecting the chemists and druggists, namely, that of the right of limited companies to carry on their particular trade, is not touched by the present Bill. Under parliamentary regulation, however, the Joint Committee to whom the matter has been referred have the power, if they so wish, to take further evidence on the point, and then to make recommendations to Parliament. Another vital issue in the hands of the Joint Committee is to consider and recommend upon the advisability or otherwise of the provisions of the Bill including Ireland within its scope. The two controversial points mentioned are of considerable public importance, and in view of the large vested interests concerned, a good deal of political activity is likely to be expended upon them during the next few weeks or months.

The Pharmacists and Quack Medicines.

AN interesting letter in our correspondence column, by a well-known London pharmacist, emphasises the state of angry revolt which has been arrived at by him and his brother pharmacists against the quackery medicine trade. It is indeed humiliating to our sense of modern social ethics to think that any self-respecting body of men should be asked to become the active participating agents in a traffic they know to be harmful, cruel, and fraudulent. If the underlying proposition of the last sentence be accepted, it follows that the newspapers, who participate in the profits of this villainous trade, are not self-respecting. It seems impossible for any man of sound sense, assuming him to be acquainted with the facts of the case, to arrive at any other conclusion. From an economic point of view, the loss to the nation in wasted money and in wasted lives must be enormous. On purely economic grounds the chemists have at length recognised that the money that should be spent on their legitimate wares is diverted to the pockets of the quack, with disastrous effects upon the misguided consumer. We are glad to believe, however, that there are high moral and ethical motives concerned in the revolt of the pharmacists against quack medicines, and we welcome them cordially as fellow-workers in the campaign which has been conducted in these columns well-nigh single-handed for so many years.

A Lunacy Prosecution.

AT the Middlesex Sessions, on March 7th, Dr. Dr. L. S. Forbes Winslow was prosecuted for "aiding and procuring a woman to receive for payment a lunatic in a house not licensed for the purpose." At the same time a Mrs. Lascelles was indicted for "receiving for payment to board and lodge a certain lunatic in a house not duly licensed for the purpose." A guinea a week was paid by the friends, and evidence was shown of neglect and want of proper supervision. The verdict of £50 against Dr. Winslow and of £10 against Mrs. Lascelles will serve as a sharp reminder that the Commissioners have no intention of permitting the lunacy law to become a dead letter. In many quarters it has become a sort of fashion to deprecate interference with the practice of harbouring insane persons, in private houses, and even to assume an attitude of defiance to the powers that be on that particular point. The action of the Public Prosecutor in the present instance will warn all such refractory persons to be "wise in time." As a victim of the unexpected exercise of the executive arm, Dr. Winslow is entitled to some sympathy. His offence was technical, but none the less it was clearly committed with a full acquaintance with the nature of his act and the possible legal consequences.

The Regulation of the Milk Supply in Ireland.

AT last the Local Government Board for Ireland have issued a much-needed and very stringent series of regulations dealing with dairies, cowsheds, and milk-shops in Ireland. Everyone carrying on the trade of cowkeeper, dairyman and purveyor of milk must be registered. The houses must be kept clean and properly ventilated and lighted. In shops, milk must not be exposed to impure air or kept in a kitchen or living room, or in any place directly communicating with a room used as a sleeping room or in which may be any person suffering from infectious or contagious disease. Vessels must be cleaned with steam or boiling water, and milk must not be distributed by persons whose hands and clothing are not thoroughly clean and free from infection and contamination. Arrangements are also made for protection against tuberculosis in cows. Swine must not be kept in any building used for keeping cows. A register shall be kept by every purveyor, setting out the names and addresses of those from whom he obtains milk. The regulations come into force on May 1st next, and, if only they are enforced, they will have a most beneficial effect on the milk supply, and through it on the public health.

The Necessity for Post-Mortem Examinations.

WE are glad to note that Dr. Symmers, Professor of Pathology at the Queen's College, Belfast, speaking at the annual meeting of the Ulster Hospital for Women and Children, drew public attention to a grave drawback to medical progress in Belfast. This drawback, which has existed for some time, consists in the manner in which every obstacle is placed in the way of the making of post-mortem examinations. Every medical man will agree with the view stated by Professor Symmers that it was not only impossible to progress very far in new medical ideas without post-mortem examinations, but it was impossible to progress at all. In Belfast, such examinations are of extreme rarity; in fact they are never made unless ordered by the coroner. In such cases the cause of death is usually an accident, and consequently the examination affords no teaching on the subject of ordinary diseases. Individuals who object to such examinations are incapable of understanding what hopeless feelings they cause in the minds of those who desire the advance of the human race. How can such advance take place unless the health of the race is first improved, and how can we learn to improve health if we are shut out from all opportunities of acquiring a knowledge of the causal factors of disease? It is one of the curses of the present age that a single faddist can stand in the way of the physical improvement of thousands of his fellow-creatures, and we fear there is at present no sign of improvement taking place. Whatever the result of Professor Symmers' remarks, he deserves high praise for making them in so pointed and public a manner.

An American Surgeon on British Surgery.

THE elder Mayo, the famous American surgeon who recently paid a visit to this country, has put on record in *The Journal of the Minnesota State Medical Association*, some of the impressions gathered by him on the state of surgery on this side of the Atlantic. He has, on the whole, formed a favourable opinion of the present condition of surgery in this country, but he notices the curious fact that the best British surgery is to be seen in the provinces rather than in London. It seems to be true, indeed, that the London surgeon is less in touch with the development of the art of other countries than is his fellow in the provinces. This is probably due to the habit of young provincial surgeons going abroad to study the methods practised in Berne, Paris, Vienna, or elsewhere, whereas the young London surgeon rarely goes beyond his own hospital. Mayo touches, too, on a gross abuse to which we have frequently adverted—the exclusiveness of the London hospitals towards accessions from without. No provincial surgeon, no Irish or Scottish surgeon, no matter how brilliant, has the smallest chance of being elected to the staff of the larger London hospitals without taking the qualifications of the London Colleges, and, in most cases, he is definitely excluded by the terms of appointment until he does so. The gross abuse of the hospital system has not escaped Mayo's notice, and he also draws attention to the lack of hospital provision for the great middle class of people of small means.

PERSONAL.

THE PRINCESS OF WALES is expected to present the Railway Challenge Shield of the St. John's Ambulance Association at the meeting at the Portman Rooms on May 15th next.

DR. FREDERICK T. ROBERTS has been elected an Honorary Fellow of the Medical Society of London.

DR. CLAYE SHAW gave a lecture at the Incorporated Institute of Hygiene yesterday on "The Psychology of Women."

SIR FREDERICK TREVES, Bart., G.C.V.O., C.B., has been appointed a member of the Advisory Board of the Territorial Army.

DR. J. H. DANBIE presided, on February 27th, at the eleventh annual dinner of the Chelsea Clinical Society at the Gaiety Restaurant

DR. P. A. SMITH, of Glasgow, was entertained at dinner by the leading Catholics of Glasgow on attaining his silver jubilee as a medical practitioner.

DR. J. LAWRENCE, of Crewe, has been presented with a handsome cabinet by the members of the Crewe Co-operative Society Branch of the St. John's Ambulance Association.

THE DUKE OF ABERCORN will hold a reception at the West London Post-Graduate College on March 18th. The Dean of the College will send invitations to such medical men as wish to be present.

DR. E. W. HOPE will read a paper on the Liverpool experience of dealing with insanitary property at a meeting of the Incorporated Society of Medical Officers of Health on March 13th.

COLONEL W. COATES, commanding Manchester companies Royal Army Medical Corps (Volunteers), has been appointed principal Medical Officer of the East Lancashire division of the Territorial Force.

LIEUTENANT-COLONEL R. H. FIRTH, R.A.M.C., will lecture on "The Sanitary Service of the Territorial Army" at the inauguration of the Public Health Laboratory at University College, Bristol, on March 20th.

THE Senate of Aberdeen University have decided to confer the honorary LL.D. on Professor Halliburton, of King's College, London, and Colonel W. Johnston, C.B., late Assistant-Director of the Army Medical Service.

A FUND was inaugurated at a meeting at Birmingham University on March 5th for the benefit of Dr. Hall Edwards, who recently lost his left forearm in consequence of X-ray dermatitis through exposure to Röntgen-rays.

MR. A. LESLIE WRIGHT, of Butterley Hall, Derbyshire, has addressed a letter to the weekly board of the Derbyshire Royal Infirmary offering to build and equip wards for children, in memory of his late wife, at a cost of between £7,000 and £8,000.

THE first of the three Milroy Lectures on Mediterranean or Malta fever, under the title of "Melitensis Septicæmia," was delivered on the 6th inst. before the Royal College of Physicians of London, by Dr. John Eyre, Bacteriologist to Guy's Hospital.

DR. WALLACE BOYCE, President of the Leinster Branch of the British Medical Association, delivered an inaugural address at the annual meeting, in which he called attention to the necessity for establishing a National Medical Service, which should be entered by competitive examination.

THE KAISER has conferred the Second Class of the Order of the Red Eagle, with Star, on Surgeon-General R. H. Quill, A.M.S., Principal Medical Officer of Netley Hospital, and the Second Class of the same Order on Lieutenant-Colonel R. S. F. Henderson, R.A.M.C., Secretary and Registrar of the Hospital.

THE Volunteer Officers' Decoration has been conferred by the King on the following medical officers:—Surgeon-Captain H. T. Challis, Lieutenant-Colonel de Burgh Birch, Surgeon-Lieutenant-Colonel J. W. Moir (retired), Surgeon-Major C. N. Lee, Surgeon-Lieutenant-Colonel J. M. Harper, Lieutenant-Colonel G. W. Sidebotham, and Major C. Downing.

WE are officially informed by the President of the Local Government Board that he has authorised for the current year the following researches, in addition to those already announced, under the grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease:—(1) Further studies by Drs. Andrewes and Horder as to the methods of inhibiting in the animal body the activities of infection by certain cocci. (2) A study of the various forms of pneumonia, especially in children, by Mr. Foulerton, F.R.C.S. (3) A study of acid-fast bacilli in butter by Dr. Nabarro. (4) An investigation of the injurious gases evolved during artificial illumination by Dr. J. Wade, D.Sc.

A CLINICAL LECTURE
ON
FŒTID BRONCHITIS.

By H. RABE, M.D.,

Ex-Interne in the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

CASES of fœtid bronchitis fall into two categories which differ widely in respect of prognosis, anatomical lesions, and clinical appearances. In the first group must be classed cases in which the fœtor, both of the breath and the expectoration, is intermittent and ephemeral, and does not affect the general health. This form of fœtid bronchitis is very apt to recur at variable intervals, and in some instances may become serious; indeed, may even determine a fatal issue. Yet, at the autopsy no anatomical lesion is discoverable to explain the fœtor of the expectoration, no gangrene of the lung or of the bronchial mucosa. Such cases were noted by Laennec, who remarked: "On two or three ocasions I found nothing on opening the body which would explain the gangrenous odour beyond proneness to putrefaction, especially of the bronchial mucus." It is to this form of fœtid bronchitis that Andral and Trousseau gave the name "curable gangrene of the lungs."

In the second group will come cases of fœtid bronchitis associated with gross anatomical lesions discoverable on post-mortem examination, bronchial and pulmonary gangrene of mucosal origin. These are, strictly speaking, cases of putrid bronchitis met with in association with dilatation of the bronchioles in which both the breath and the expectoration have a pronounced putrid odour. The constitutional symptoms indicate infection and intoxication of the organism. Recovery is possible, but rare, the patients usually succumbing to gradually-induced cachexia. Post-mortem we find gangrene of the bronchi and even of the lung The lesions have been thoroughly investigated by Cornil and Ranvier under the name "superficial gangrene supervening in dilated bronchioles."

As a rule these two classes of cases are included under the same head. It is, however, preferable to differentiate between the two anatomical types, describing each under an appropriate name. The clinical type described by Lasègue as curable gangrene of the bronchi, characterised by intermittency of the fœtor and almost invariable recovery, might be styled "simple fœtid bronchitis." The clinical variety dependent upon gangrene of the bronchial mucosa, which is necessarily of grave import, might be described as "putrid bronchitis, gangrenous bronchitis, bronchitis with superficial gangrene of the walls, or gangrene of the bronchi." The diagnosis no doubt will always be a matter of considerable nicety, but the bad constitutional state and the extreme fœtor of the expectoration will usually suffice to establish it.

Etiology.—The fœtor of the expectoration may, under exceptional circumstances, make its appearance in the course of an attack of ordinary or post-influenzal bronchitis. It is more frequently met with in cases of old-standing chronic bronchitis supervening after mental or physical strain or as the result of a chill. It is especially apt to present itself in alcoholic, malarial, and arterio-sclerotic patients. Broncho-pneumonia, especially the form that complicates typhoid fever, favours its appearance along with dilatation of the bronchi. The same remark applies to chronic pneumonia and pleurisy with pleural sympexis. According to Trousseau, multiple pregnancies and prolonged lactation predispose thereto, and Rindfleisch attaches considerable etiological importance to acute pneumonia occurring in the subjects of bronchial dilatation.

The fœtor of the breath and expectoration is often observed in the course of pulmonary tuberculosis. This fœtor, due to putrid fermentation, is promoted by pre-existing bronchial dilatation, by ulceration of the bronchi or lung, by aërobic and anaërobic infection of the cavities, and by gangrene of the walls of the cavities. It is also met with in cases of pulmonary carcinoma.

Pathological Anatomy.—The lesions discovered at the post-mortem examination of persons who have succumbed to the disease just described differ, of course, according as the case was one of simple fœtid bronchitis or of fœtid bronchitis complicated by gangrene of the bronchi. In cases of simple fœtid bronchitis we find the lesions of bronchiectasis. The mucosa is thickened, congested, often ulcerated, and may be covered with a blood-stained or muco-purulent fluid with a filthy odour, but there is no gangrenous ulceration, and, as Graver noted, if the bronchi be washed the fœtor disappears, showing that it was merely due to decomposition of the bronchial secretions. In the lungs we almost invariably find recent foci of broncho-pneumonia, either suppurating or gangrenous. In some instances putrid infarcts consequent upon gangrenous emboli are found in the viscera.

Numerous bacteriological investigations have been made, but they give such discordant and inconstant results that they cannot be relied upon. The staphylococcus pyogenes, mentioned by some observers, is probably present as the result of secondary infection, and has no direct connection with the original fœtor.

Pathological Physiology.—We may unhesitatingly reject the ancient theory of the fœtor of the expectoration being due to a special diathesis, to individual predisposition, and to abnormal secretion of bronchial mucus. Whether the case be simple or complicated by gangrene, the cause is really the invasion and multiplication of certain micro-organisms on the bronchial surfaces. In all probability, in cases of intermittent fœtor, we must incriminate aërobic germs. These exist normally on the bronchial surfaces, where they lead a saprophytic existence, but under the influence of chronic inflammation of these canals they become virulent and set up putrid fermentation of the bronchial mucous secretion, with the formation of butyric, valerianic, caprylic, and other acids. At the same time toxins are formed which cause fever, general depression, and emaciation. This decomposition, however, does not appear to aggravate the bronchial lesions, and under appropriate treatment the alarming symptoms subside, and recovery ensues until the condition recurs.

Symptoms and Course.—Lasègue describes the symptoms of simple fœtid bronchitis in the following terms:—"A person of variable age, of more or less robust constitution, usually much run down in consequence of fatigue or numerous antecedent maladies, is attacked by bronchitis which at first presents no special features. The oppression is moderate in amount, the cough severe, the expectoration fairly copious, of the nature usually met with in advanced cases of this affection. Then the sputum becomes more abundant and purulent, and is sometimes extremely fœtid. This first attack may pass without attracting attention, the fœtor of the expectoration becomes less or disappears, but the bronchitis persists, with little or no fever. After a variable interval the bronchitis seems to get worse, the expectoration becomes greenish-yellow, brown, or even grey, and the fœtor is more pronounced than before.

The fœtor varies in intensity. Sometimes it is not very marked, is only noted after paroxysms of coughing, and it is usually the patient himself who is the first to complain thereof. In other cases it is so pronounced as to invade the whole ward, but even so it is never as horrible as in true pulmonary gangrene. As Grisolle observes, it is a sickly, sweet, repulsive odour recalling that of sulphuretted hydrogen.

In these cases the fœtor of the expectoration is on a par with its copiousness, which in its turn is dependent on the degree of dilatation of the bronchi. Such patients may spit up a couple of pints or more of mucus, and as this is often thrown off suddenly, and is accompanied by nausea and even vomiting, one is apt to suspect a pulmonary or pleural vomica. Collected in a glass, the expectoration separates into three layers, an upper layer which is frothy and holds flakes of pus in suspension, a middle layer which is sero-mucus and contains a few yellow threads, and a lower layer which is frankly purulent and shows small granular masses known as Dittrich's buttons, made up of agglomerations of epithelial elements, fatty acids, crystals, and various microbes. It is important to note that no elastic fibres are ever present. Of course, in cases in which the bronchial dilatation is limited the quantity of expectoration is proportionally diminished.

The physical signs found in the lungs are, as may be imagined, most variable. We get the symptoms of chronic bronchitis, of bronchial dilatation, with or without pleuro-pulmonary sclerosis, moist subcrepitant râles, tubular or cavernous *souffle*, with cavernous râles when the bronchial cavity is large enough.

As already mentioned, fœtid bronchitis, even when simple, always affects the general health. The patient loses appetite, wastes, and the temperature rises to 37° or 38° C., the strength failing day by day.

The duration of the attack varies. The symptoms may improve in ten or twelve days, but are usually prolonged for two or three months, possibly even for five or six months, with alternating periods of improvement and recrudescence. A diminution in the amount of expectoration is the first favourable sign, soon followed by lessened fœtor. The general state improves, the temperature falls, and, usually after a few weeks' convalescence, recovery ensues. But the lesions of bronchial dilatation persist, the patient continues to cough, and he empties his bronchi every morning. It must be clearly borne in mind that even when the recovery, or, rather, the improvement, has lasted for months, or even years, these subjects remain very liable to recurrence. Mere fatigue, or chill, or excess of any kind may forthwith determine the return of the fœtid bronchitis. Moreover, if the remissions be of only brief duration, the patient's strength gradually fails, and he becomes cachectic. The cough and dyspnœa become more pronounced, and very often the pleuro-pulmonary sclerosis rapidly spreads. Fever and emaciation ultimately determine the fatal issue. In the same way, during one of the relapses, sphacelus of the bronchi may occur, or even pulmonary gangrene of the lung.

Under these circumstances the character of the expectoration changes, it loses its muco-purulent aspect, and becomes rusty or blackish, and at the last stage we find fragments of necrosed pulmonary tissue containing elastic fibres. The fœtor is very pronounced and invades the whole ward.

The symptomatology also affords evidence of profound constitutional disturbance. From the onset the patient complains of pains in the sides with increased dyspnœa. There is complete loss of appetite and extreme prostration. The pulse becomes frequent and compressible. The temperature chart does not present the irregularity and marked evening exacerbations of pulmonary gangrene, and oscillates between 37° and 38.7° C. The complexion becomes leaden, and the patient little by little assumes the aspect of the phthisical. During the last few days of life there may be œdema, purpura, and colliquative diarrhœa. Gangrene of the bronchi does not kill as rapidly as primary parenchymatous gangrene; it may run on for six or eight weeks, but invasion of the pulmonary tissue always precipitates the fatal termination. Whichever form of fœtid bronchitis we may be dealing with, its course may be chequered by more or less copious pyretic or apyretic hæmoptysis. This complication is not of much gravity, although Lancereaux records two cases in which death promptly followed profuse hæmoptysis.

Prognosis.—Whatever variety of fœtid bronchitis presents itself, the prognosis must always be guarded. Certain authors, it is true, claim that sphacelus of the bronchi may be recovered from, but this can only be in cases of simple fœtid bronchitis, for the prognosis in gangrenous dilated bronchioles comports a grave prognosis, the patient invariably succumbing to toxi-infection. Then, too, the prognosis is aggravated by the complications that may supervene: putrid pleurisy, fœtid pyo-pneumothorax, gangrenous abscess of the brain, &c. On the other hand, the cure of simple fœtid bronchitis may be hoped for, especially when the bronchiectasis is of limited extent, and the peribronchial pulmonary sclerosis does not tend to spread. But, unfortunately, the attacks of fœtor tend to become more and more frequent, each succeeding attack being more severe, until at last the patient dies in the course of a still more violent attack. Death is due to progressive cachexia, or follows some pleuro-pulmonary complication.

Diagnosis.—Fœtor of the breath and expectoration are not met with exclusively in Lasègue's curable gangrene and in Briquet's disease, but also in certain affections of the lungs and pleura, as well as of the digestive tract and upper air passages. The first question we have to ask ourselves, therefore, in presence of a patient with fœtid breath, is, What is the seat of the causal lesion?

The odour may emanate from the nasal fossæ or bucco-pharyngeal cavity (ozæna, tertiary syphilitic rhinitis, ulcerated pharyngeal cancer, &c.). Similarly, laryngeal epithelioma often renders the breath horribly offensive. The exploration of these different cavities will enable us to incriminate or eliminate them as the source of the fœtor.

The opening into the bronchi of encysted purulent pleurisy, whether interlobar or of the main cavity, is associated with marked fœtor of the expectoration, and the physical signs show the existence of an intra-pulmonary cavity. Suddenness of onset constitutes an important differential sign, and the appearance of vomicas has been preceded by an attack of some acute thoracic affection. Nevertheless, the pleural abscess, even after opening up communication with the bronchi, may take on a sub-acute or chronic course. The patient expectorates a certain quantity of ozænic pus, intermittently, most frequently in the morning, and the breath retains its character in the intervals. It is then impossible to decide whether the patient is suffering from encysted pleural abscess with periodical evacuations, or from putrid bronchitis with or without gangrene of the mucosa. Béclerc reports a case of this kind in which the diagnosis could not be settled without the aid of skiagraphy which rendered it possible to eliminate the hypothesis of pleural abscess and to recognise the presence at the base of the lung of a patch of pleuro-pulmonary sclerosis. It turned out to be a case of dilatation of the bronchi with fœtid secretions. In all such cases, therefore, we must have recourse to this method of exploration.

Certain extra-thoracic purulent collections (abscess of liver, subphrenic abscess, perirenal abscess, &c.) sometimes open into the bronchi. The gangrenous odour of the expectorated matter may lead us to suspect primary putrid bronchitis, but close examination of the patient and the course of the affection will usually enable us to identify the starting-point of the symptoms.

As a rule, the special character of the breath and sputum will suggest the idea of parenchymatous gangrene of the lung. Briquet's syndrome can usually be distinguished easily enough from primary sphacelus of the lung, even in cases in which the odour is peculiarly offensive and the signs of toxi-infection rather alarming. Lobar gangrene commences suddenly, solemnly, so to speak, and, at the same time, the patient complains of intense, persistent pain in the side with severe dyspnœa. The gravity of the constitutional disturbance points to profound infection. These signs are wanting in superficial sphacelus of the bronchi, an affection which is characterised by a gradual onset and a less striking symptomatology. The gangrenous focus is revealed by exact, circumscribed physical signs (dullness *en bloc*, souffle, crepitant and sub-crepitant râles, &c.). The physical symptomatology of putrid bronchitis is always somewhat vague and very polymorphous.

Directly we have made out the exact origin of the respiratory fœtor a second problem arises. It is due to simple putrid fermentation of stagnant secretions in the bronchial cavity, or is the bronchiectasis complicated with true gangrene of the mucosa. We have just contrasted the clinical characters of the two syndromes. The intensity of the odour, the gangrenous fœtor of the sputum, the progressive decline of the general health, and the protracted duration of the attacks, are all points that militate in favour of Briquet's disease. Nevertheless, these presumptive signs may be wanting, and microscopical examination of the sputum will then decide the diagnosis; in cases of bronchial sphacelus by showing the presence of elastic fibres, and their absence in cases of simple fœtid bronchitis.

Gangrene of the mucosa follows sometimes fixation in the bronchi of septic foreign bodies. The diagnosis of this etiological variety of putrid bronchitis does not present any difficulty. It is met with in the aged, in paralytics, and in the insane, in whom the passage into the air passages of a foreign body gives rise to attacks of dyspnœa with extreme distress, cyanosis and threatening asphyxia. In healthy adults bronchoscopy may furnish valuable information in respect of the diagnosis of the seat of obstruction.

Treatment.—This is based on the following therapeutical indications: To modify the bronchial secretions, and to facilitate their expectoration.

Inhalations and fumigations of eucalpytus, turpentine, thymol, and creasote fulfil the first indication. Leyden recommends inhalation of oxygen; Béclerc, intra-tracheal injections of oxygenised water and mentholated oil. We may also give internally terpine, turpentine, guaiacol, and creasote, which, however, must not be continued indefinitely for fear of upsetting the stomach. Gimbert and Bucquoy advise tincture of eucalyptus; Chauffard, tincture of benzoin; and Lancereaux, hyposulphite of soda in drachm doses daily. Sublimed sulphur (3 to 5 grains in the 24 hours) may also be recommended, and the waters of Eaux-Bonnes, Cauterets, Barèges, &c. If the stomach becomes intolerant, we must have recourse to hypodermic administration.

Kermes and ipecacuanha promote the elimination of the bronchial mucus, thus fulfilling indication number two. The protracted duration of fœtid bronchitis and its frequent recurrence, as has been pointed out, bring about gradual exhaustion and steadily increasing cachexia. This must be combated by the administration of ferruginous tonics, hypophosphites, and the like.

Note.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Robt. Saundby, M.D., MSc., LL.D., F.R.C.P.Lond., Senior Physician to the General Hospital, Birmingham. Subject: "Sudden Death."***

LETTSOMIAN LECTURES, 1908.

MALIGNANT DISEASE OF THE CÆCUM.

By CHARTERS J. SYMONDS, M.S., F.R.C.S.,
Surgeon to Guy's Hospital.

Lecture III.

The Lecturer first referred to the accepted view that extirpation was the only remedy for malignant disease, and that the success attending early removal demands on our part its early recognition. The difficulty that sometimes occurred in accurately estimating the nature and extent of abdominal swellings gave rise to two evils; firstly, to the postponement of operation till the appearance of certain well-known signs of disease occurred, and so to the loss of valuable time; and secondly, it led us to lose confidence in the value of those signs pointing to inoperable disease, and so to lead to exploration when unnecessary. Cancer of the intestine, being a painless infection, did not become manifest until the appearance of a tumour, or the signs of obstruction. It was, therefore, important to remember that when these signs arose the disease had been in existence some time, often for many months. Referring especially to cancer of the large intestine, excluding the rectum, he pointed out that the operative success was very satisfactory, even with removal of large portions. The lymphatic infection was slow to occur, and the extension to the peritoneum and other organs was long delayed. While advocating early, and even extensive removal in suitable cases, he did not wish anyone to think lightly of such operations, where a disaster might cut short a life with a year or more of satisfactory existence. Such operations demanded a knowledge when to proceed with, and when to abandon, an operation, what limits to set to the undertaking, and a patience that will not fail when further but removable infiltration is found after all had apparently been removed, and that will examine, and see that no weak point in the defence had been left unprotected. The first part of the large intestine, he pointed out, was particularly suitable for resection, on account of the length of the mesentery, the ease with which it can be handled, and the satisfactory condition in which the parts can be left, for in joining the ileum to the transverse colon, the functions are practically undisturbed. The two chief signs of malignant disease of the cæcum were the presence of a tumour and early intestinal colic. The typical appearance of such a tumour was next described. It appears as a movable, hard, well-defined mass, so close to the abdominal wall that it may be grasped by the hand, and even lifted forwards. From a position of rest it can be moved downwards, swinging inwards as it descends towards the median line, and the margin of the rectus. Upwards towards the ribs it takes a more vertical course, and does not pass into the loin. It again can be moved directly inwards towards the umbilicus. During this movement a gurgle will often be heard. While the range of movement varies with the natural mobility of the cæcum in any individual, and while it may be limited by fixation of the growth, it was held that the appearances described did not occur in any other tumour about the cæcum. The characteristic of the colic was that at first the pain was central, and later in the cæcal region. It was of brief duration, attended with gurgling, and often by vomiting, unaccompanied by nausea, so that an interrupted meal may be returned to. Where the disease begins in the ileo-cæcal valve, colic will precede the appearance of a tumour. On the other hand, when the disease begins above the valve, colic may be entirely absent.

The first case illustrating the lecture was that of a lady, æt. 48, operated upon in December, 1897. The first symptom was "pain in the stomach," in July and August. In November the pain became more severe, and right-sided, there was gurgling, and, at the height of the spasm, sickness. A tumour, easily handled, and movable downwards and towards the median line upwards, occupied the position of the cæcum. There was characteristic coiling of the intestine, and the typical colicky pain of obstruction.

The cæcum, with a considerable piece of the mesentery, was removed, the colon closed, and the ileum attached to the side of the large bowel by a Murphy's button. The specimen showed the disease to have begun at the ileo-cæcal valve, thus explaining the early obstruction. The appendix shared in the growth, and the ileum showed marked thickening. The recovery was rapid, and she was alive and well in February, 1908, more than ten years from the operation.

As showing how the mobility of the tumour, and the presence of good health may lead to error in diagnosis, a case of a lady of 34 was cited, who was seen in June, 1900, after an attack of abdominal pain. The next morning the temperature was 100, and a lump was found in the situation of the appendix. As it did not subside, Mr. Oram, under whose care the patient was, brought her for an opinion. The mass was painless, easily handled, and had a range of movement exactly like the first case. The colicky pain was equally characteristic. Immediate operation was advised, but, unfortunately, delay was recommended by a leading physician. on account of the mobility of the tumour, and, therefore, its apparently simple character, and also on account of her age. When seen six months later, the tumour had greatly increased, there was frequent pain, and the night before there had been an attack due, apparently, to perforation. Short circuiting seemed now the only remedy, and with this view the abdomen was opened. The manipulation required to obtain the end of the ileum, raised the whole mass from the iliac fossa, and it seemed quite possible to extirpate it. This was carried out, the ileum being united as before to the colon, and in the same manner. Though severe, the operation was well borne, but she died in three days from hæmatemesis, the vomiting beginning immediately after operation. The strength was not quite sufficient to bear so extensive a proceeding. The difficulty of defining the limits of operation was pointed out when the only consideration must be the welfare of the patient, and not percentage of success, though removal was surgically possible.

The next was a case where the growth was more diffused, and the tumour flatter and less defined. This was a gentleman of 75, seen with Mr. Donald Smallpeice, in January, 1904, for abdominal pain, indigestion, loss of weight, and a doubtful swelling in the right ilio-lumbar region. On deep inspiration the lump came forwards, and could be pushed in any direction, the mobility being unusually extensive. Unlike the usual tumour, this returned into the loin, and was almost lost to touch. He had typical colic, brief, sharp, accompanied occasionally with sickness unattended with nausea. Being a vigorous man, and likely to bear a fairly big operation, exploration was advised with a view to removing the cæcum. This was successfully carried out, and the ileum being united as before to the colon, an uninterrupted recovery followed. At the date of the lecture he was alive and well, and able to walk and cycle as usual. The growth in this case involved the cæcum and ileo-cæcal junction and was of a diffused variety. The peritoneal coat was thickened from old inflammation, probably starting in the appendix, as this body was enlarged and thickened.

A case without colic was that of a lady of 59, under the care of Dr. Steele Perkins. This patient had accidentally observed the tumour when handling the abdomen. There had been no pain or tenderness. The tumour was a little higher than usual, but had much the same characters, and seemed a favourable one for removal. The patient had some cardiac trouble, and was of a most nervous disposition. In March, 1904, resection was completed on the same lines as in the others, and was followed by a rapid recovery. The specimen and drawing showed the disease to be situated just above the ileo-cæcal orifice, thus explaining the absence of colic. On account of the glandular infection nearly the whole of the ascending colon was removed. Some glands on the spinal column were left. This patient died some 18 months after operation from some cardio-pulmonary malady, there being no evidence of recurrence.

The next case referred to was that of a man of 52, under the care of Dr. Carrell, of Ilford. The clinical signs of this case showed the disease to be more extensive, and the chance of extirpation doubtful. The signs of obstruction were marked, and the tumour less movable and less defined. Being a man of good physique and remarkable energy, it was decided to remove the affected parts, if possible. On exposing the tumour, a coil of small intestine was found adherent to the anterior aspect of the growth. This was first resected, and united by two continuous sutures. Then the cæcum, half the ascending colon, and a large piece of mesentery with numerous glands were removed. Recovery was interrupted by the most incessant hiccough, lasting four days. Then the skin was noticed to be bulging, and serum to exude from the wound. On opening the scar, a coil of small intestine was found, covered with lymph. The catgut sutures had given way owing to the hiccough. Without anæsthesia the intestine was returned, and the wound closed with two rows of silk. The man recovered, and took his food well. Later the whole scar and rectus muscle became infiltrated with growth, sinuses formed, and he died some months later with a fæcal fistula. It was suggested that infected peritoneal serum must have existed, and entering the wound with a coil of intestine, determined the deposit of cancer. In the operation the growth had not been torn or broken, though infected lymphatics must have been divided. In this connection, it was pointed out that this must often occur, and yet no similar result had been seen. It, therefore, seemed due to the cancer material being implanted on connective tissue.

Diagnosis.—Under this heading the various tumours occurring in the ileo-cæcal region were referred to. Those due to disease of the appendix were smaller and fixed. When permanent, the cause was a calcareous covered concretion. The resemblance of suppurating growth to appendicitis was illustrated by two cases, in one of which the sinus had healed. The occurrence of sudden pain in the iliac fossa, with a rise of temperature, and the finding of a lump was referred to as the earliest evidence of a malignant growth in two cases.

Tuberculosis of of the cæcum was discussed, and reference made to Professor Hartmann's paper read before the Society last year. One case, occurring in the lecturer's practice in 1895, was referred to. Here there was a fistula with a large irregular fixed mass. Excision of the cæcum was followed by recovery. It was thought that the age of these patients, usually under 30, and the earlier fixation of the tumour would decide, though cancer of the large intestine at 28, 19, and 16 had come under the notice of the lecturer.

Tuberculous glands in the ileo-colic angle had been operated upon in four instances, all in young people. The tumour in these cases was smaller, was fixed, and there was no obstruction.

One case of actinomycosis was referred to ("Med. Chi. Trans." vol. 75) as showing the resemblance to the suppurating stage of malignant growth. In the early stage actinomycosis resembled from its fixation, hardness, and persistence that form of appendix tumour due to a calcareous concretion, and not a new growth.

Limits of Operation.—While resection was out of the question in the presence of secondary deposits, and with infiltration of the posterior wall, he thought moderate infiltration of the anterior wall did not always negative operation. One such case was related in which he had successfully removed an infiltration scar—the result of a former operation in another's hands, together with the cæcum. Recurrence took place after a short interval. Adhesion and infiltration of a coil of small intestine was not considered to negative extirpation. The presence of pallor, as a rule, indicated a condition that would not endure a long operation. He referred to pallor as due to disseminated growth—true cachexia—to small hæmorrhages, as in gastric carcinoma, and to necrotic changes in the growth. When this last is the cause removal may be carried out when the patient is vigorous. One such instance was referred to where the hepatic flexure, ascending colon, and cæcum were successfully removed, the man being still active and well nearly four years later.

Murphy's button for making a junction between the end of the ileum and the side of the colon was referred to as preferable to direct suture. It was important to use a button not more than 13/16 of an inch in diameter, to place a row of Lembert's sutures round the junction, and, whenever possible, to surround the parts with the great omentum.

Reference was made to the importance of postponing anastomosis when the contents of the bowel were septic, and to two cases fatal from this cause. When palliative treatment by anastomosis was carried out, he saw no necessity for dividing or otherwise excluding the ileum below the junction. He thought such a plan determined the accumulation of fæces in the colon between the growth and the junction.

ORIGINAL PAPERS.

PERSONAL HEALTH PROBLEMS—EARLY AND LATE GROWTH.

By J. LIONEL TAYLER, M.R.C.S., L.R.C.P., Lond.

Now that the study of the individual health factor has, with the inspection of school children, become a public question, it is to be hoped that this problem of personal health will receive the attention that it deserves.

At the same time it is desirable that it should be clearly recognised that it is an altogether different study from that of public health.

It may or may not be a fair assumption to make to assume that, in one thousand school children of a certain age, a given number should be a certain average height, and that a lower standard implies an unhealthy or degenerate condition; but there can be no question that a like principle applied to particular individuals would be wholly fallacious. There are so many types of individual children and adults of both sexes that, until we know the healthy type standard to which any given person should conform, it is impossible for medical men to generalise on the relative healthiness or unhealthiness of small size, small weight, and shortness of stature. If we do not realise this danger there will be a real possibility of social disaster following medical efforts in this direction, as quite healthy differences will be confused with unhealthy.

As a small contribution to this difficult subject, I should like to draw attention to the phenomena of early and late growth.

It has long been known that some families mature quickly and others slowly; that children of the former group are big and tall for their age, while the latter are often small at first, but gain in height markedly from adolescence onward.

A chance observation on one man led me to note the co-incidence of three conditions of late growth: little hair on the face, pubes, etc., and exceptionally small testicles. On making inquiries into other cases, I also found this same association of poorly-developed sexual features and growth continuing four to seven or eight years after puberty.

To realise this it is necessary to distinguish between sex development and sex specialisation. There are many men who have fully developed beards, broad shoulders, and other masculine characters associated with large breasts, wide hips, and smoother feminine limbs. Such people are not deficiently sexualised, but they are unspecialised, and they probably revert to the old savage state of man, when man was more feminine and woman much more masculine. For such undifferentiated, mixed sex development the commonly accepted terms, femininism for the male and masculinism for the female are accurate and suitable. The kind of man or woman that I am referring to is, however, one who, in the strictest scientific sense, is unsexualised, and the term *asexualism* is, therefore, more suitable to apply to such a person's condition.

Such individuals are, especially in early adult life, thin and rather pinched-looking, having straight, inartistic figures, narrow shoulders, and hips and limbs that appear long by their lack of form, and the smallness of contrast between leg and thigh and forearm and arm. In men, particularly, I have noticed a prominent, sharp Adam's apple, its projection being, I think, due to deficiency in the size of the thyroid gland and to nearness of the wings of the thyroid cartilage to each other. Both men and women have thin voices, almost completely lacking in that richness and mellowness of tone that makes the human speech and song seem so pleasant to the ear; and it is curious that, though often not ill-natured, they are nearly always more or less disliked by individuals of the opposite sex, and, in my experience, seldom marry.

Some races are, it is well known, lacking in secondary sexual development, but the rate of growth does not appear to be known in them, nor has any comparison been made with other more evolved peoples. It would probably be a much easier task to determine whether castrated animals grow for a longer period than uncastrated. (*a*)

The question is one of peculiar interest at the present time, as recent studies of the comparative heights of underfed poorer and well-fed wealthier children, have assumed that the advantage that the latter possess is due solely to diet and general surroundings, when it may result from other causes.

The following brief summary of six cases of asexualism may therefore possibly be not without interest in this connection :—

(1) Man, over thirty years of age, with sloping, narrow shoulders, feebly developed lower jaw, little hair on face, very prominent Adam's apple, thin, hard voice, narrow hips and straight limbs. Of a mentally eccentric character, inclined to practice silly jokes on his friends; was very small till nearly fifteen years of age, and then grew rapidly and steadily till twenty. He comes of a family, all of whom reach adult height late, and all less strongly sexed than average people. One sister is not masculine, but almost devoid of sex characteristics. Food and surroundings have always been exceptionally good. Nothing remarkable in parents, except that one is much more capable of culture than the other. Disliked by women and "made fun of" by men.

(2) Man, over thirty, head very small, lower jaw feebly developed, hair on face average, prominent Adam's apple, rough voice, shapeless, thin figure, narrow shoulders and hips. Large, thin Roman nose, downy hair on body. Mentally much above average. Testicles rather small. Only sister and mother of same asexual type, and the man is disliked by women, and his sister by men. Growth rapid between fifteen and twenty years; very small before fifteen. Food and surroundings slightly deficient. House badly ventilated.

(3) Man, over thirty, one of large family, all healthy, all living, and all late in completing growth, has a feebly-developed lower jaw, facial hair average, rather prominent Adam's apple, narrow shoulders and hips, and thin, straight legs. "All the family thin." Food and surroundings very good. Not unpopular with men or women, deficient in ideas.

(4) A whole family—father, mother, two adult daughters, and one brother—all belong definitely to this type; all have thin, pinched Roman noses, very unpleasant thin, metallic voices, and straight figures. All are feeble mentally, and are actively disliked and ridiculed by both sexes. The brother and mother have marked Adam's apples, and the daughters ones that are easily observable. Food and surroundings average.

(5) Man, under thirty, little development of facial hair, feeble jaw, pointed Adam's apple, voice lacking richness, brother (at one time typical "hooligan type") and himself growing noticeably after fifteen years. Testicles extremely small. Father like son in asexual characters. Food and surroundings poor.

(6) Man, under thirty, of degenerate, but rather talented family, sexual organs infantile, voice incompletely broken, with little signs of hair on face and does not require to shave, treated as a child by most men and women, grew very rapidly after fifteen. Food and surroundings good.

All of the six men are unmarried, and only the third case has the least prospect of marriage. *All* of their sisters are, with the exception of the last case, unmarried, and in all six cases there is evidence that the unsexed condition is present in the other members of the family. Curiously, only one case is under 5ft. 10in., and no woman under 5ft. 6in., and two of them are nearly 6 feet in height; though another instance, which I am not sufficiently certain of in reference to age when growth was most marked to include among the others, is short.

I think the growth of young recruits, of "defective development," after joining the Army, could often be traced to this cause of late evolution, and the fact that the young under-sized hooligan type of lad is so seldom traceable in the adult form, is also, I believe, largely attributable to this reproductive retardation.

As confirmatory facts on this point, I may say that I have so far always found on inquiry that this narrow shouldered and hipped type is fast growing, though it has not been necessary for the other reasons which the patient consulted me about to make the requisite physical examination to prove or disprove my first impression. Thus, while only six cases have been studied, a much larger number have been observed.

That wide shoulders are associated with masculine tendencies, and narrow with non-masculine, the difference between the bull and the bullock; the stallion and the horse demonstrate, and that wide hips are feminine characteristics which increase in width and capacity at puberty, is, of course, a well-known fact.

If thickness and squareness of shoulders are evidence of masculine development, and width of hips and fulness of thighs are evidence of feminine strength, then it must be conceded that these slim types are to some extent asexual, but whether healthy or unhealthy is at present uncertain.

Laycock ("Nervous Diseases of Women," p. 28) alludes to a case of nymphomania reported by Alibert, in which the lower part of the body was extraordinarily plump and well-developed, as contrasted with the upper; and I have seen one similar instance myself in a young girl about eighteen years of age whom I treated for an hysterical malingering condition, and this patient was strongly attracted to the life of a prostitute. It is, of course, very difficult to prove that men whose figures are fully developed in the chest regions and taper downwards are more passionate than others, but my impression is that such is the fact.

Professors Geddes and Thompson, in their work on the "Evolution of Sex," refer to experiments of Selheim, which seem to show "that in mammals of both sexes the removal of the reproductive organs markedly prolongs the period of bone development, and has thus an effect on the shape of various parts."

The cases considered in Gould and Pyle's "Anomalies and Curiosities of Medicine," on "Precocious Development," seem, on the other hand, to largely support this position from an opposite point of view, namely, that early and very rapid growth is frequently, if not always, associated with early reproductive development.

Some definite information on the subject is much needed, not only because we do not know if the late-growing type is, or is not an unhealthy one, but also on acount of the fact that it appears small and stunted at school, when afterwards it often passes the average, and thus it vitiates school statistics in which height considerations have been included.

(*a*) See Selheim's experiments, alluded to further on. The Veddas of Ceylon seem to have many asexual characteristics, and their diet appears to be an insufficient one; many other races are deficient in sexual hair. (beard, etc.). Novelists have described this type—see Mr. Collins in "Pride and Prejudice,"—but I cannot state when it was first noticed in literature.

Further, if the asexual form is unhealthy, it may be that our education system is fostering it, or some other element in our social life may be favourable, and its presence should throw light on many obscure phenomena of sterility, and also on the increasing difficulty experienced by many women in regard to lactation.

I should be much interested to know if other medical men have noticed similar facts.

I have not referred to the influence of the thyroid, possibly the pancreas and pituitary glands in affecing the amount of bodily growth, though these are interesting questions, but have simply contented myself with pointing out that height—and the same is probably true of weight—is not simply a question of food and good hygienic surroundings. Thus, in the very interesting report of Dr. Leslie Mackenzie and Captain Foster (Glasgow School Board), it is shown that the "one-roomed child, whether boy or girl, is on the average distinctly smaller and lighter than the two-roomed; and the two-roomed than the three-roomed; and the three-roomed than the four-roomed." Without disputing the fact, which is borne out by the inquiries of the Inter-Departmental Committee on Physical Deterioration, I yet wish to draw attention to other factors which an individual study of different persons reveals. What may be true of a class is not necessarily true of single members of that class, and yet it is the unconscious forgetfulness of this that is the special danger in health problems for medical men, at the present time, to avoid.

SOME PRACTICAL POINTS IN THE TREATMENT OF GONORRHŒA.

By H. DE MERIC, M.R.C.S.,
Surgeon to In-Patients, French Hospital, London.

THE treatment of gonorrhœa, it must be confessed, has not advanced very materially during the past century. The gonococcus, it is true, has been discovered during this period, but no very definite means have been found to destroy it, and, by destroying it, to stop the inflammation and its consequences. There are, indeed, those who assert that it is still questionable as to whether the discharge is caused by the presence of the gonococci, or whether the discharge comes first and the gonococci afterwards. With regard to the first hypothesis, we must remember that in an old urethritis which has lasted for months and months we can still find gonococci; for the second hypothesis we must bear in mind the mild urethritis which is the outcome of connection with a woman suffering from leucorrhœa, or even with a woman either immediately before or immediately after her menses, to this being added an excessive consumption of alcohol. In this urethritis there are no gonococci; yet, if the discharge be neglected and at the same time the patient continues to absorb large doses of alcohol, it will take on all the characteristics of true gonorrhœa, and gonococci will make their appearance. It might be suspected in such a case that the woman was infected and gave the malady to the man; but I have often known cases (and they must constantly occur in the practice of other surgeons who see much of venereal disease) in which, of two men who have had connection with the same woman, one is not infected by her (and this is the individual who is accustomed to her), while the other, who has only been with her for the first time, and under circumstances of leucorrhœa, alcohol, etc., mentioned above, gets a non-specific urethritis which, if neglected, becomes a true gonorrhœa.

Since the discovery of the gonococcus by Neisser, very little real improvement has taken place in the treatment of the condition. We have still the same routine, which may be conveniently divided into—(1) the internal, and (2) the external treatment. With reference to the former, we still have the same procession of balsams, at the head of which copaiba still proudly marches, although oil of sandalwood disputes its right to command, a claim which, in recent years, seems to have been largely admitted, probably owing to the particularly obnoxious taste of copaiba. The best way to administer copaiba is in the form of the French opiat, which is a combination of oil of copaiba and cubebs rubbed up in a mortar so as to form a paste, which has such a disgusting taste and smell that it can only be administered in "Hosties." Sandalwood oil has also a disagreeable taste, though less nauseous than that of copaiba. It is best given in capsules. For the last thirty years in cases of gonorrhœa, when it has been necessary to order internal remedies such as those where the advent of epididymitis has precluded the prescribing of local external treatment, I have administered the above drugs with varying success, but I have always had a feeling that I was groping in the dark, and that I could never give a definite opinion as to the curative action of these remedies, which appeared to me to exert their modifying power over the disease more with reference to the idiosyncrasy of the individual patient than to the general characteristics of the disease. I have endeavoured in many series of cases to discover what was the peculiar idiosyncrasy of the individual which caused success on some occasions and failure in others, but I must confess that up to the present time I have been baffled. This much, however, I have observed—viz., that the inability of the drug to produce curative effects has not been more marked in those patients in whom the stomach and kidney troubles have been produced by the remedy—quite the contrary; for I have very often seen excellent results with regard to the gonorrhœa both by copaiba and sandalwood oil in cases in which I have had most reluctantly to stop the administration of either drug on account of intense nausea with eructations, combined with increasing kidney trouble; sometimes, too, the latter without the former. On the other hand, I have frequently seen patients take either copaiba or sandalwood oil for long periods with perfect impunity as regards the stomach and kidneys, but without producing any appreciable effect on the discharge. My mind has, therefore, always been open to the trial of any remedy which would offer a really curative effect without having to be stopped on account of extraneous complications.

My attention has lately been drawn to a preparation called gonosan, which I have tried at the French Hospital on a certain number of cases. Gonosan is the name given to a combination of one part of the resin of Kava-Kava with four parts of the best West Indian essence of santalum album. Now, Kava-Kava, the resin of Piper methysticum, is described by the best authorities as a diuretic and a motor depressant, resembling coca in its action when taken in small and moderate doses, and producing intoxication when taken in large doses. With regard to santalum album, it has been proved that its essence, and more especially the essence of West Indian santalum, loses to a large extent its noxious properties for the stomach and kidneys in proportion to its degree of chemical purity. The combination of these two substances seemed to me a very happy one, as I judged that the properties of the Kava-Kava would hold in check any noxious qualities of the santalum—if any remained in the carefully prepared West Indian product—and at the same time would aid the latter in its curative effects. I see that Boss, of Strasbourg, who first brought this remedy into prominence, has great confidence in the calming, almost anæsthetic action of the Kava-Kava, which he considers causes a paralysis of sensibility in the nerve terminals of the urethral mucosa. In addition, it possesses vaso-constrictor properties local to the urethra which must cause a certain amount of anæmia of the mucous membrane, diminishing thereby the irritation and preventing an extension of the inflammation. The German physicians go so far as to explain the diminution of the gonococci caused by gonosan by the hypothesis that the drug alters the culture medium; they also ascribe anaphrodisiac properties to the drug, and these undoubtedly must be of paramount importance in cases of chordee.

In view of the great advantages claimed for gonosan by many eminent medical men in Germany, a few of which advantages I have briefly alluded to above, I resolved to give the preparation a trial, although for many years I have as much as possible ceased giving the so-called curative internal agents for gonorrhœa, relying entirely on injections, lavages, etc. But those of my in-patients at the hospital suffering from gonorrhœa have, of course, some complication such as epididymitis, and this complication precludes the ordering of an injection for the time being. I had, therefore, every incentive to try a new remedy, more especially one coming to us with such excellent credentials. My opportunities for forming a very definite opinion in the short time I have ordered gonosan have necessarily been somewhat limited, but I must say that in the few cases I have had under my observation two of the advantages claimed for the drug have been amply realised, and these are undoubtedly the most important—namely, the curing of the discharge and the absence of any stomach or kidney symptoms.

CASES.

A. G., æt. 18. Admitted to the French Hospital with very painful epididymitis. This proved to be very rebellious to treatment. The epididymitis got slightly better, but the whole testicle became inflamed and enlarged, so much so that on the presumption that the testicular affection might be tuberculous, Calmette's ophthalmo-reaction was tried, but with a negative result. When the orchitis got better, a discharge appeared in the urethra. There was a history of gonorrhœa three months previous to admission. Gonosan was administered, and the remedy entirely stopped the discharge in a week. In this case, however, the gonosan produced slight gastric symptoms, but it was found that this was owing to the remedy having been administered at first on an empty stomach.

G. T., æt. 23. Admitted with epididymitis, and also a discharge from the urethra. Gonosan was ordered, which absolutely cured the urethral running in a fortnight, when the patient left the hospital, the epididymitis being also quite well.

E. D., æt. 36. Admitted with gonorrhœal rheumatism and a discharge from the urethra, for which last gonosan was ordered. The patient left the hospital twelve days after admission at his own request. The gonosan had cured the discharge, and the rheumatism had been much relieved by appropriate treatment.

H. M., æt. 26. Admitted for gonorrhœal rheumatism. Gonosan was administered for the discharge, and the man left the hospital cured in a fortnight.

E. P., æt. 25. Gonorrhœal rheumatism and gonorrhœa. This was a most successful case as far as gonosan was concerned, as in ten days the drug cured the discharge, which had been the thick and purulent discharge of gonorrhœa.

L. C., æt. 24. Balanitis, gonorrhœa, and epididymitis. Discharged cured in four weeks, gonosan having cured the gonorrhœa.

With reference to the external or local treatment of gonorrhœa and urethritis, I need not repeat the high esteem in which I hold urethral injections as administered by the patient himself, upon which I have dwelt in previous articles. Injections, when the patient has been taught the proper way to employ them (a highly important matter), must form the basis of all treatment for gonorrhœa when the case is one that offers no such complication as might for a time contraindicate their employment. But I would like to say a word on the success I have had in the revival of what is really an old treatment for the urethritis which persists for months in some patients, and which is a source of much mental worry to them. This urethritis, which is often, but not always, characterised by what is termed the "morning drop"—the French call it the "goutte militaire"—is generally the result of the patient leaving off treatment too soon, and resuming his ordinary absorption of alcohol, especially of beer. The discharge is liable to be very rebellious to treatment, especially as the patient only comes for our advice after it has lasted for weeks, frequently for months. The difficulty in curing this condition by ordinary means, such as urethral injections, arises from the fact that the inflammation which causes it is situated in the so-called posterior urethra, that is to say, the part of the tube posterior to the anterior layer of the triangular ligament and to the compressor urethræ muscle. Therefore the action of this muscle, which is brought into play when the anterior urethra is filled with injection, prevents the fluid from penetrating into the posterior urethra. This has been overcome by some surgeons, especially in America, by the irrigation treatment whereby the liquid is forced past the constriction caused by the muscle, and so brought into contact with the posterior urethra; this is effected by raising the vessel containing the fluid which flows through a tube connected with a nozzle, this last being inserted into the anterior urethra. I must say this method never appealed to me; in the first place I do not think such force should be applied to so delicate a tube as the urethra; in the second place, even putting aside my first objection, I consider that the fluid is forced in the wrong direction, thus carrying all the impurities of the urethra backwards towards the bladder. For some time, especially in my private practice, I have utilised a method which I have characterised as old, because I have heard of it from my earliest days, though I have only employed it extensively during the last few years: it consists in filling the *bladder* through a silver catheter with warm boracic solution, and letting the patient pass it through his urethra as forcibly as he can after the catheter has been withdrawn. There are one or two little points of technique about this simple operation. The catheter should have a double canal, as it is often useful to draw off the first liquid with which the bladder has been filled and replace it by some fresh lotion. The patient should empty his bladder of any contained urine before the catheter is introduced. I need hardly insist on the importance of aseptic measures. The part of the flexible tube just above its junction to the catheter should be nipped with catch forceps before the lotion is poured into the glass vessel at the other end of the tube; when the lotion has been poured in, it can only penetrate as far as the catch forceps; the india-rubber tube should then be gently massaged between the thumb and fingers from below (where the forceps nip it) upwards (to the glass vessel) so as to expel all the bubbles of air which otherwise would be forced onwards into the bladder with the lotion. The fluid is then allowed to flow into the bladder through the catheter by the removal of the catch forceps. Sometimes it is well to arrest the flow at short intervals; the lotion may feel too warm to the patient; he may be nervous, etc., besides it is always best to hold the forceps in readiness towards the end of the lavage, when the patient's own sensations as to the fulness of his bladder will be a guide to the surgeon. The bladder should be filled as far as possible to its greatest capacity, in order that the expulsive stream may be as powerful as possible. This lavage has in most cases to be repeated two or three times at intervals of three or four days. The cure, I find, is generally effected after two or three *séances*, but in some patients it may be necessary to perform the slight operation five or six times. It causes no pain whatever if the surgeon be careful and gentle in the passage of the catheter, taking the patient's attention off by talking to him if there is the least spasm. It is well to reassure the patient on this point, as many men are very much alarmed at the idea of having an instrument passed. Needless to say that during the whole period of treatment the patient must carry out a strict hygiene and refrain from all alcoholic beverages. He should wear a suspensory bandage, take an occasional saline purge if necessary, and keep as quiet as possible. I may say that out of the last 12 cases of long continued and obstinate urethritis which I have treated by lavage, in only one instance have I had to complete the cure by two instillations of nitrate of silver, and in this patient the morning drop had already been present for two years when he came under my care.

My experiences with gonosan have been so favourable that in a case where I should formerly have proceeded to instillation, I would now always try gonosan first, and I should be surprised if its exhibition, together with strict hygienic, dietetic, and other precautions, did not render the instillation unnecessary.

CLINICAL RECORDS

LABOUR SHOCK.

BY R. J. KINKEAD, M.D.DUB.,

Professor of Obstetrics, Queen's College, Galway; Physician and Gynæcologist to the Galway Hospital; Fellow of the Royal Academy of Medicine in Ireland, &c., &c.

IN the report of the Rotunda Hospital for the year ending 31st October, 1906, three cases of "Labour Shock" are given.

The case I now report is similar; the hæmorrhage following delivery was not profuse, nor greater than that generally observed in normal cases.

On August 1st, 1907, a little before 12 o'clock noon, I was called to see Mrs. X., —a 2nd para. She was in charge of an experienced nurse.

Her first child had been born dead after a protracted parturition, and as she had been many hours in labour the nurse feared that the same thing might again occur, and sent for medical assistance. I had not attended her in her former confinement, nor indeed ever seen her before. She seemed in good condition, no signs of exhaustion: the head was engaged in the brim, vertex, L A O presentation, the os was dilated, but the anterior lip not quite retracted.

The pelvis was roomy, and although there was a little trouble in getting on the forceps owing to a somewhat prominent sacral promontory, there was no difficulty in extracting a large male child.

Immediately after the birth of the child I administered a drachm of Long's liquor ergotæ.

I kept my hand on the uterus and expressed the placenta twenty minutes after delivery of child.

The uterus was a bit sluggish in contracting, but was never distended, my fingers slipped easily down below the promontory, and the palm of the hand and thumb perfectly controlled the uterus.

After the nurse had washed her I proceeded to insert two sutures for a slight laceration of the perineum, the nurse taking my place in following down the contraction.

Up to this time the patient had been looking and feeling well, talking, and in good spirits As I put in the first suture a woman standing beside her exclaimed, ' She is looking bad: what's the matter with her?"

She had become suddenly collapsed; whisky was administered; strychnine and ether injected hypodermically, and normal saline into the areolar tissue, hot bottles applied, and everything possible was done, but in vain; she died in less than an hour.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

CARCINOMA OF THE BREAST.—MR. EDRED CORNER operated on a woman, æt. 52, who had had a lump in the upper and outer part of her breast for about a year. The lump had given her no pain or inconvenience until three months ago, when she noticed a tightness of the anterior axillary fold whenever she raised her arm. On examination, with the flat of the hand, one felt a mass in the breast towards the axilla; the mass had indefinite margins, and was not attached to the great pectoral muscle, as it could be moved easily in the direction of the muscular fibres when they were put on the stretch by abducting the arm; further than that, it was not attached to the skin; hence, Mr. Corner pointed out, the tumour presented practically no classical signs as they are given in text-books of a scirrhus of the breast; but growths, when they commence in the upper and outer quadrant of the gland, often possess, he said, very peculiar features. A carcinoma extends to a very large extent by the way of the lymphatic vessels. In other parts of the breast the lymphatics of the deep portions of the glands communicate freely with those of the pectoral muscle and of the skin; hence a neoplasm in these situations speedily becomes adherent to the muscle and to the skin which dimples over it; but in the upper and outer quadrant of the breast the lymphatics of the gland communicate with the lymphatic vessels which run straight to the axillary glands; hence a carcinoma in this situation more quickly involves the axillary lymphatic vessels and glands than it does the overlying skin or the deeper lying pectoral muscle. The result of this peculiarity of the lymphatic vessels is that a growth in this situation presents no retraction of the nipple, no dimpling of the skin over it, or any of the classical signs of carcinoma of the breast as usually described except the presence of a hard tumour. In the case of this patient the hardness of a tumour of the breast was obscured by the presence of a large quantity of fat. In the light of the difficulties of ascertaining the exact nature of tumours in the upper and outer quadrant of the breast, a tentative diagnosis of carcinoma had been made. The first step of the operation, Mr. Corner said, must be to ascertain the exact nature of the tumour by the means of an exploratory incision. In making such an incision it was necessary that it should be made of sufficient length to allow the margins of the wound to be everted, so as to show fully the characters of the cut surface of the tumour. In the present case it could be seen that the section showed all the naked eye appearances of a scirrhus—the white appearance, the dense branching arrangement of the fibrous tissue, and the concave surface, etc. The tentative diagnosis of carcinoma of the breast had been confirmed, and now it was necessary to undertake the full extensive operation for its relief.

The incisions Mr. Corner then made extended from the arm above the axilla to below the breast on the chest wall; the edges of the skin along these large incisions were well undercut because the object of modern surgery for the relief of carcinoma of the breast was, he considered, to remove a large area of the fat and fascia, and not so much of the skin as was formerly taught. This was done, and at the same time the sternal half of the pectoralis major was removed and the latissimus dorsi at the back of the wound and the axillary vessels, with the brachial plexus at the top of the axilla, were exposed. The wound was then closed and dressed in the usual way, the dressings being retained in position by a many-tailed bandage, which, he thought, added much to the comfort of the patient and to the convenience of the surgeon if any dressings are subsequently required. No drainage was employed, because he has found that if great care is given to hæmostasis, patients do better if the wound is not drained. Sometimes, in order to remove completely all fat, fascia, and lymphatic glands from the posterior part of the axilla, it was advisable to make a further incision extending from the original one downwards and backwards, so as to turn down an axillary flap of skin; this incision was extremely useful in such cases where it was advisable that the wound should be drained, and this can be done by inserting a small tube in the posterior part of the incision, or by merely inserting the stitches which close it further apart. Mr. Corner said that from a clinical point of view the case he had just operated upon was most instructive. It taught us, in the first place, that malignant disease in its earlier stage was unaccompanied by pain; secondly, it had demonstrated to us yet again that all tumours in the outer and upper quadrant of the breast must be regarded as of most serious import until they have been proved to be otherwise. They may be malignant, although they may present none of the usually accepted signs except the presence of a lump; thirdly, the lymphatic glands early become invaded, which must render the prognosis in these cases more serious than when the growth is in another part of the breast. Thus he would particularly direct attention, and impress upon students the serious significance of all lumps in this part of the breast, and the extreme desirability of their removal with as little delay as possible.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Meeting held Friday, February 14th, 1908.

The President, Dr. W. R. Dawson, in the Chair.

ALCOHOL AND MENTAL DISEASE.

The President, after thanking the Fellows for electing him, said that his paper was intended merely as a contribution to a general discussion on alcohol. Apart from personal predilections, the uncertainty existing with reference to the effects of that drug was largely due to deficient appreciation of the influence of individual diathesis and of the varying effects of different doses. On reviewing the evidence, it appears that with normal individuals, under appropriate circumstances, small doses properly diluted and taken with food not too frequently are physiologically beneficial. With larger doses the matter is otherwise. Alcohol was either taken in moderate doses frequently or in large doses occasionally. A drunken bout is not only a microcosm of insanity, but indicates the probable course of chronic alcoholism in the same individual. Different persons show different symptoms. When alcohol is taken more continuously, though in small doses, the same order of degradation is observed —the "high-level" moral and other late-acquired qualities being first affected, then the motor and sensory functions, and, lastly, those of mere nutrition. Such a person is mentally abnormal, and, given a faulty diathesis, is certain to become technically insane, but there is no hard and fast line between the two conditions. Even of the technically insane all do not enter asylums, and, therefore, a complete estimate of the relation of mental disease to alcohol is impossible. Of asylum cases the prevailing opinion seems to be that about 15 to 20 per cent. are due to alcohol, but the influence of the personal equation, the difficulty of ascertaining the facts of each case, the confusion of cause with effect, as well as other circumstances, render it almost certain that this estimate is too high. The regional distribution of insanity does not correspond with that of either alcoholism or drunkenness, and it seems probable that not more than 10 per cent. of the asylum cases are genuinely attributable to alcohol. These, however, probably constitute the smaller part of the cases due to this cause, especially if those in which it was merely contributory be counted. These latter must be numerous, owing to the susceptibility to alcohol of persons with any hereditary or acquired brain weakness. In parenthesis it may be noted that, though there is the strongest evidence of the evil effects of parental alcoholism upon the offspring, the question has really nothing to do with the transmissibility or otherwise of acquired characters, the phenomena being sufficiently explained by the deleterious action of the drug upon the germs of the future individual. Chronic alcoholism produces worse effects than occasional drunkenness, and bad spirits worse effects than pure ethyl-alcohol. As regards the forms of insanity due to alcohol, certain symptoms are suggestive of this cause —viz., impulsiveness, suspiciousness, confusion with hallucinations, loss of memory for recent events, and fabrication of imaginary occurrences. The most purely alcoholic forms are delirium tremens, Korssakoff's psychosis, hallucinatory-confusional insanity, and alcoholic dementia. In neuropathy we have mania *a potu* and chronic alcoholic insanity, including alcoholic mania, melancholia, and paranoia, and the more severe forms of alcoholic dementia. Lastly, we have dipsomania. Pathologically the changes in the more chronic forms are found round the fissure of Rolando affecting chiefly the large pyramids. If alcohol be cut off, the mental improvement is usually rapid, but of the habit itself compulsory prolonged total abstinence is the only cure, though some of the drug and other treatments may assist. The writer hoped that the paper would be discussed.

The MacDermot said he had, during the past seven years as Inspector of Prisons, visited one of the Irish prisons almost every week, and had tried to make himself familiar, as far as possible, with the penal and family records of the prisoners. He had, in addition, superintended the work of the State Inebriate Reformatory at Ennis during the past four or five years. It was from that field of observation—outside the general observations that one makes in the world—that he would speak. Those observations he had tried to reduce to order by bearing in mind two distinct theories on the question of alcoholism. The first was the neo-Darwinian theory, that a great number of the human species had an original taste for alcohol, a taste which, being natural, was not acquired. According to that theory, acquired habits were not transmissible, and since the taste for alcohol was original, the only possible cure which he could see, in accordance with that theory, was the elimination of the drinker, and the only feasible way of accomplishing that end was to expedite the catastrophe by multiplying the number of public-houses. With that theory he disagreed *in toto*. The facts of his experience did not fit in with it in any particular. The other theory had been called the theory of Lamarck—that a taste for alcohol was an acquired habit, and that acquired tastes were transmissible. The adoption of the latter theory would give great confidence and lead to greater interest in all temperance movements. History supplied them with instances of inebriate races which had become temperate, and which were an example of the transmissibility of temperance. His own observations of prisoners had shown him that the examples of the criminal type came mostly from the cities, and that their parents were of inebriate habit; while the prisoners who came from the country were not of the asymmetrical type, and were not the heirs of those transmissible qualities, including intemperance. The public had changed their point of view as regards alcohol; they no longer looked at it from the point of view of the pulpit, or the philanthropist, but from the point of view, so to speak, of the College of Physicians. They all wished for health, strength, and longevity, and when the medical profession taught sound views on the use and action of alcohol, he was satisfied that it would not be the elimination of the drinker which they would see, but the elimination of drink.

Dr. Walter Smith said their chief knowledge of the scientific effects of alcohol was a quite recent growth, and he thought the turning point was reached by Schmiedeberg, who, with unanswerable arguments, demolished the view still held by many, that alcohol belonged to the class of stimulants. Alcohol was an essential member of the narcotic group of substances. That had been a great gain, and had put the medical profession on a better basis. Most medical men were much more cautious now than in his student days about the administration of alcohol, especially in acute disease. They had learned that most diseases got on better without alcohol, and they had learned that its careless use by their profession in the past had hurried many persons to premature graves. At the same time they had to guard against exaggerations and inexact statements appearing in recent writings on the subject, such as that alcohol is one of the most frequent causes of consumption. It was Utopian to expect that legislation would make them a nation of teetotallers. It was a physiological fact of Nature that people would have luxuries. One of the most important questions at the root of the matter was that of the nutritive value of alcohol. Physiologists told them that its possible value as a food was more than discounted by its harmfulness; and it was said that moderate drinking had a most injurious influence on health and life, and that all alcoholic drinks should be avoided. If that was so, he would like to know how it was that the most progressive European nations were moderate drinkers. He believed the truth of the matter was that in limited quantities of alcohol 90 per cent. of it was oxidised in the body and furnished energy. It had been shown by experiment in America that alcohol could replace equivalent quantities of carbohydrates and fats, especially when the supply of these was deficient in their diet. To a person in health, on a sufficient diet, alcohol was absolutely unnecessary, and possibly injurious to some people; but it was idle to deny its possible value as a food in some cases. No one drank pure alcohol, and its effects were infinitely modified by the other substances which were combined with it. It was absurd for a Royal Commission to try to answer the insoluble question—What is whisky? They might as well ask—What is mud? The points which related to the public in regard to alcohol were: (1) Its effects in producing visceral disease, (2) its leading to all sorts of crime, and (3) its influence on the nervous tissue. The latter was a very complicated question, but there could be no doubt as to the deleterious effects of long-continued doses of alcohol on the brain. It was admitted by most physicians that the continued use of alcohol tended to cause glycosuria, which led to various mental symptoms. As regards treatment of alcoholics, he did not at all side with those who maintained that it was dangerous to withdraw alcohol suddenly, and he refused to undertake medical treatment unless he could at once put patients under conditions of abstinence.

Dr. **DONNELLY** said the way to effect permanent good was to reach the coming generation by educating the parents of the present, especially the mothers. A great responsibility rested with the medical profession. In the past it had sometimes used its power, in regard to alcohol, to the detriment of the community, but a great deal of good was being done through the agency of the profession in putting before the people the physiological action of alcohol and the deleterious effects of over-indulgence. It was exceedingly unwise of physicians to permit alcohol as a beverage without marked restrictions as to its discontinuance after a time. It should not be prescribed in any respect except as a drug, and in his opinion should never be given to mothers who were suckling their infants.

Dr. **DELAHOYDE** who confessed himself to have been a life-long total abstainer who had never tasted any liquor that was brewed or distilled, said he did not think that statistics fully represented the amount of insanity which was directly traceable to alcohol. He had known many cases of insanity which had never gone to an asylum or hospital, and which would not be included in the returns on which they based their deductions. He himself, on occasions, prescribed alcohol, but always under strict conditions.

Dr. **FALKINER** agreed with Dr. Delahoyde that the mortality from alcohol was not really stated in the statistics. They had very often to look to the mortality of certain diseases of the nerves and viscera, and of pneumonia, to get a reliable idea of the number of deaths that were directly due to alcohol. In regard to insanity also, statistics were very misleading; he doubted if, in many cases, insanity was the cause of mortality at all. A great number of lunatics died of tuberculous diseases and dysentery. The term "alcoholic poisoning" was a loose one, and he had taken the trouble to get particulars which would enable him to judge whether persons so certified had actually died of acute alcoholic poisoning.

Dr. **STRITCH** said that one of the greatest evils of alcoholism was the indiscretions to which it might lead an individual, and there was little hope for the cure of the chronic drunkard unless they could get his active co-operation.

Dr. **BEWLEY** said that the causation of insanity was complex. Alcohol affected the mind injuriously, but of itself it did not cause insanity unless there was something else present—something which he might call a congenital predisposition to insanity. It was quite impossible to ascertain all the factors or to place much reliance on arguments based on statistics which referred to such complicated matters as alcohol and insanity.

Dr. **WINTER** said that, in his experience, the people who felt most benefit from alcohol were those of a nervous type. If the medical profession was more sparing in recommending alcohol to such people it would do a certain amount of good in battling against the evil done by the drug.

The **PRESIDENT** replied.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD FEBRUARY 27TH, 1908.

The President, Mr. **THOMAS BICKERTON**, in the Chair.

CASES.

Mr. **NIMMO WALKER** showed a case of

TUBERCULOSIS OF THE CONJUNCTIVA

in a boy, æt. 9. The outer two-thirds of the conjunctiva of the lower lid of the right eye was occupied by a raised flat-topped growth, with bright red nodular surface, which did not extend to the palpebral margin; the eye itself was unaffected. The diagnosis was confirmed by the presence of lupus on other parts of the body, from which it was probable that the eyelid had been inoculated. Mr. Walker pointed to the difference between this true tubercular lesion and the common phlyctenular ulcer, which was often called strumous or scrofulous conjunctivitis, but which, in his opinion, was not due to the tubercle bacillus, but was akin to eczema. He proposed to excise the growth, and to graft mucous membrane from the lips to prevent symblepharon and consequent trichiasis.

The **PRESIDENT** remarked upon the rarity of the condition.

Dr. **STOPFORD TAYLOR** suggested treating the condition by means of zinc "ions" from a solution of sulphate of zinc.

Dr. F. H. **BARENDT** suggested that the zinc "ions" should be used for treatment by inserting a zinc needle as the positive terminal into the conjunctiva, and by this method a better result would be obtained.

Dr. J. H. **ABRAM** and Mr. F. T. **PAUL** showed and related a case of

COLLOID CANCER OF THE STOMACH

in a boy, æt. 13½. The patient was admitted into Dr. Abram's ward for pain in the stomach. The history was given that vomiting had begun suddenly three months previously, and had continued, accompanied by loss of appetite and constipation. Nutrition was very poor. The outstanding feature of the case was the great dilation of the stomach, with visible peristalsis. A hard mass was felt lying transversely midway between the xiphisternum and the umbilicus. With diet, etc., vomiting was kept in check, but the boy steadily lost weight, and Mr. Paul was asked to see him. Mr. Paul opened the abdomen and found a large tumour occupying the pyloric region and spreading along the lesser curvature to the cardiac end. The tumour had been regarded as either tubercular or other inflammatory infiltration, causing obstruction, but it had all the appearances of a large carcinoma. Anterior gastrostomy was performed, and the boy made a good recovery, with great relief to his symptoms, but the relief can only be looked upon as temporary. During the course of the operation an infiltrated gland was removed, and the microscopical examination of it revealed the true nature of the tumour as being colloid cancer—a condition of excessive rarity at this age.

Dr. E. E. **GLYNN** said that he had examined some 580 specimens of cancer from the wards and post-mortem room of the Royal Infirmary since January, 1900, all of which, except about 80 of the post-mortem cases, had been verified microscopically. The total number of cancer cases in persons of 30 years and under was 22. Of these, 7 were 25 years and under, while 3 were 20 years and under, including Mr. Paul's case. All these were confirmed microscopically except

3, which were obviously cancer from the post-mortem appearances. The distribution was as follows:—Cancer of the breast, 6; of the stomach, 5; ages, 23, 27, 28, 28, and 13; four being the so-called variety; cancer of the rectum and sigmoid, 4, 2 being colloid, jejunum 1, cervix uteri 1, epithelioma of the scalp 1, testicle 1, penis 1.

The case was also discussed by Mr. Keith Monsarrat and Dr. P. Marsh.

BIER'S METHOD IN DERMATOLOGY.

Dr. **Stopford Taylor** and Dr. **R. W. Mackenna** showed several forms of Bier's vacuum apparatus which they had used in the practice of dermatology. Dr. Stopford Taylor said they had used the apparatus extensively during the last few months with much advantage in cases of lupus, acne, furunculosis, various forms of œdematous eczema, and leg ulcers. They had found a negative pressure of 2½ lbs. per square inch, sufficient to produce a copious discharge of serum from callous ulcers, which is followed by the rapid formation of healthy granulations. Œdematous eczemas drained in the same way rapidly heal up, and the vacuum process applied in cases of lupus, while of great value in itself, is of special efficacy when used in conjunction with the Finsen lamp. The method flushes the tissue from within, and, by bringing serum laden with opsonins to the seat of the disease, aids phagocytosis.

The method was discussed by the President, Sir James Barr, and Dr. Given, and Dr. Taylor replied.

CHOLECYSTITIS.

Mr. **Keith W. Monsarrat** read a paper on cholecystitis. He expressed the view that cholecystitis should be studied, not as an incident in so-called gall-stone disease, but as a well-defined inflammatory visceral lesion, in which infection from the intestinal canal was primarily throughout the causative agent. The formation of gall-stones was one of the results of the infection; once formed, they exerted an important influence on the gall-bladder infection, just as an appendix concretion might be responsible for a marked modification of the result of an appendicitis. Clinically there were two phases of cholecystitis which presented themselves for study, the acute attack and the interval between the attacks. Illustrations were given of the phlegmonous type of attack, of the suppurative and the catarrhal. The two first could be differentiated from the last by the attention to the clinical signs, the importance of this differentiation being that they required operation during the attack, while the last did not. The symptoms during the interval between the recurrent attacks depended upon the lesion left, and varied from a condition of practical health to one of chronic invalidism. Illustrations were given, particularly of cases presenting gastric symptoms. The differential diagnosis of the acute attack and the chronic invalid condition was considered, and the indications for operation discussed.

Mr. **F. T. Paul** thought that Mr. Monsarrat's analogy between cholecystitis and appendicitis was quite reasonable, the essential difference being that one structure was in the direct line of infection, whilst the other was a good deal removed from it. He deprecated cholecystectomy except when absolutely necessary, which was very rarely the case, and he quoted various cases illustrating the varieties of cholecystitis and the occasional difficulties experienced in diagnosis.

Mr. **Douglas Crawford** said that, although the signs of acute cholecystitis occasionally led to a mistaken diagnosis of some other acute disease, as appendicitis, yet the symptoms were so severe that an operation was undertaken. It was different, however, with the more chronic forms of infection of the biliary passages. In these cases gall-stones were almost invariably formed in the gall-bladder, and might give rise to dyspeptic troubles. Such cases require very careful examination, for at any time grave complications might arise, such as perforation of the gall-bladder, or a severe acute infection may be added, with serious, if not fatal, results. He quoted cases illustrating his remarks.

Dr. **Abram** said he was afraid the diagnosis of cholecystitis was not so simple as the paper would suggest. He quoted a case where just such symptoms led to operation, yet the gall-bladder was found perfectly healthy. He agreed as to the *rôle* of infection in the causation of cholecystitis and gall-stones. He had met with one case of cholecystitis due to typhoid infection; the patient made a good recovery without operation. He had seen a case of gall-stones in which operation was necessary. A woman, æt. 35, had typhoid fever at the age of 24; attacks of pain began five years later, jaundice after another year, and it recurred several times. A bacteriological examination of the gall-bladder contents by Dr. E. E. Glynn demonstrated the presence of bacillus typhosus.

The paper was also discussed by the President, Sir James Barr, Drs. Davies and C. Williams, and Mr. W. T. Thomas and Mr. Monsarrat replied.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Pathological Evening.

Meeting held February 7th, 1908.

The President, **Richard Lake**, Esq., F.R.C.S., in the Chair.

The folowing specimens, etc., amongst others, were shown:—

Mr. **Cecil H. Leaf**.—(1) Two specimens of fibroid of the uterus removed by supra-vaginal hysterectomy. (2) Multiple cystic tumour of thyroid removed by operation. (3) Carcinoma of rectum, removed by Kraske's method.

Mr. **McAdam Eccles**.—Specimens illustrating some of the less common diseases of the testis.

Mr. **Pardoe**.—Two specimens of malignant hypernephroma, and microscopical slides.

Dr. **Arthur**.—X-ray diographs.

Mr. **Donald Armour**.—Goître (exophthalmic).

Dr. **A. E. Russell**.—Congenital narrowing of the subclavian artery, simulating aneurysm, associated with angina pectoris.

Mr. **Swinford Edwards**.—Enlarged prostates.

Dr. **Low**.—Pathological specimens:—Tumour of liver; spine showing erosion by aneurysm; intestine showing dysenteric ulceration; pachymengitis hæmorrhagica; aneurysm of transverse arch bursting into œsophagus.

Dr. **Macnaughton-Jones**.—(1) Two specimens illustrating the difference between ovarian and tubo-ovarian blood cysts. (2) A series illustrative of malignant disease of the ovaries. (3) A series illustrative of sclerosis and cirrhosis of the ovaries. (4) Three specimens of primary tuberculosis of the Fallopian tube. (5) Four coloured plates of the female pelvis (showing all the organs). (6) A skiagraph of calculus of the kidney with the removed calculus. (7) A skiagraph of the ankle-joint showing ankylosis (after bullet wound).

Mr. **Aslett Baldwin**.—Horseshoe kidney. Knee-joint showing osteo-arthritis; section of anthrax of cheek due to fly-bite, and other microscopic specimens.

Dr. **Ernest H. Shaw**.—(1) Tuberculous tumours in the brain of a child. (2) Mixed tumour of submaxillary salivary gland. (3) Fibroids of uterus, one calcified. (4) Cystic hæmorrhagic carcinoma of the breast.

Mr. **Keetley**.—Malignant growth of the intestines.

Dr. **Dauber**.—Uterine fibroids.

Mr. **Firth**.—Sarcoma of the intestine.

Dr. **Phineas Abraham**.—Photographs of skin diseases.

ULSTER MEDICAL SOCIETY.

Meeting held Thursday Evening, March 5th.

The Vice-President, Mr. **Andrew Fullerton**, in the Chair.

Colonel Dodd, R.A.M.C., read a paper on the treatment of venereal disease in military practice.

Mr. **A. B. Mitchell** read a paper on duodenal ulcer, which will shortly be published.

Mr. **R. J. Johnstone** showed (*a*) a uterus removed from a case of Cæsarian section; (*b*) a ruptured uterus.

CORRESPONDENCE

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 8th, 1908.

Treatment oe Fœtid Bronchitis.

The fœtidity of bronchitis is caused by microbian infection of the stagnant mucus in the dilated bronchial tubes, and the treatment should have in view the necessity of modifying the condition of the secrection by the aid of antiseptics and facilitating expectoration.

The first is attained by placing antiseptic agents in direct contact with the mucous membrane by means of inhalations, fumigations, or spray.

The antiseptics recommended by Rabé are: eucalyptus, turpentine, thymol, creasote.

Paul prefers combining one or two of these drugs:

Phenic acid, 1 dr.
Thymol, 15 gr.
Proof spirit, 4 dr.
Water, 1 quart.
To be inhaled.

Turpentine has been recommended by Skoda.

Turpentine, 2 oz.
Water, 1 quart.

Instead of inhalations, medicated vapour.

Leyden employs inhalations of oxygen and prescribes phenic acid internally, while Béclerc declares having obtained, in two cases, rapid cessation of the fœtid secretion by intra-tracheal injection of a mixture of oxygen water and menthol dissolved in olive oil.

Several agents as terpin, turpentine, guaiacol, creasote, have been prescribed internally, but the stomach shows intolerance when these substances are continued for some little time. Eucalyptus, tincture of benzoin or hyposulphite of soda are currently employed. Grinbert and Bucquoy are very much in favour of tincture of eucalyptus, 20 drops three times a day in an appropriate mixture or capsules of eucalyptol. Lancereaux prefers hyposulphite of soda at the rate of one drachm a day, which dose should not be exceeded for fear of exposing the patient to diarrhœa.

When the stomach becomes intolerant, the hypodermic method might be utilised.

Guaiacol, 2 dr.
Olive oil, 3 oz.
An injection morning and evening.

The second therapeutical indication, that of facilitating the expulsion of the mucosities is best realised by employing expectorants as ipecacuanha or antimony.

Tuberculous Adenitis of the Neck.

Tuberculous glands of the neck are exceedingly common, and when left to open of themselves or when opened by the bistoury, give rise to those unsightly and indelible scars which compromise the social status of the patient, and this is especially so in the case of girls. For this reason, Dr. Calot, of Berck-sur-Mer, protests strongly against the classical method of removing the gland or of opening and draining the abscess when formed. Neither does he advocate abstention, only for a time, so as to give a chance to general treatment: cod-liver oil, sea air, tonics, etc. If after four or six months no improvement is observed, he prescribes the following treatment which possesses the all important advantage of causing no tell-tale scar.

When the gland is very hard, he injects a modifying liquid to bring about retraction or, on the contrary, suppuration according to the quantity of the solution employed.

To obtain sclerosis and absorption he injects into the gland 4 or 5 drops of camphor and naphthol every three days.

Camphorated naphthol, 1 dr.
Glycerin, 1 oz.

The volume of the gland increases a little after the first injections, and at the end of three weeks or a month it begins to diminish, and disappears completely after four or six months. Seven or eight injections are given in all.

To obtain suppuration he injects from 20 to 40 drops of the same solution every day. In from four to six days the gland begins to soften, and in a few days more the abscess is fully formed.

When the abscess is completely ripe, he draws off the pus by means of a trocar and a small aspirator, and then injects through the same trocar from which the aspirator is detached from half a drachm to one drachm of—

Olive oil, 2 oz.
Creasote, ½ dr.
Iodoform, 1 dr.

The injections to the number of eight are made every four days.

When the abscess threatens to burst spontaneously, he limits the operation to aspiration of the pus only, and without a consecutive injection. In such case the trocar is passed first through the healthy skin, and the aspiration is repeated until the skin over the abscess has recovered its integrity, when the injections are commenced. After the eighth injection aspiration is renewed once or twice, and, the cavity being completely empty, the parts are compressed by a few layers of cotton wool and a bandage, so as to bring in contact the walls of the abscess.

Dr. Calot has treated in this manner hundreds of cases with invariable success, and leaving but the faintest trace of the little operation, to the great satisfaction of the patients and their families.

Sycosis of the Beard.

Calomel, 15 gr.
Oxide of zinc, 30 gr.
Lanoline, 1 dr.
Vaseline, 3 dr.

Or,

Extract of hamemelis, 15 gr.
Camphor, 1 dr.
Chalk, 30 gr.
Black soap, 15 gr.
Lanoline, 1 dr.
Vaseline, 3 dr.

Apply at night. In the day-time this ointment might be replaced by—

Salicylic acid, 6 gr.
Boric acid, 15 gr.
Oxide of zinc, 30 gr.
Vaseline, 6 dr.

Warm lotions of camomile morning and evening, while the beard should be cut close with the scissors.

If the disease is due to a parasite (trycophyton), the above treatment is insufficient; prolonged epilation will be necessary in such cases.

GERMANY.

Berlin, March 8th, 1908.

At the Verein für Innere Medizin, the subject of
Chemical Hypnotics
was discussed. After an introduction from the chemical point of view by Prof. Dr. Thoms, Hr. Ziehen took up the discourse from the clinical side. He restricted his observations to the employment of the chemical hypnotics in nerve diseases, leaving out mental diseases, infectious diseases, etc. No statistics could be compiled, he said, as the cases differed endlessly from each other, and only the impressions produced on the mind of the physician could be dealt with. He included the sedatives in his survey. He discussed the theme clinically, as the bedside phenomena and the chemical composition did not by anv means cover each other. One must rather analyse the nature of the insomnia, and make the choice of the particular hypnotic from the indications afforded by the analysis.

In the first group the bromine salts were the most effective hypnotics, not the hypnotics proper. He gave the bromide of sodium in daily doses of from 1½ gm. to 2 gm. for some days together, and in this way a satisfactory sleep was generally induced in from 8 to 10 days. In obstinate cases a more prompt effect was produced by neuronal or bromural, as bromine developed a stronger action in those combinations. The first, in suitable doses of from 1 to 1½ gm., scarcely ever showed any unpleasant by-effects; neither did it become less active by repetition. Bromural had a similar action, and it was a harmless hypnotic, especially for children. It was allied to the preparations of valerian, which had a certain hypnotic effect in mild cases.

In the second group, that of motor insomnia, hyoscine and duboisine acted very well indeed. They were not given subcutaneously, but per os in doses of 1-3rd to ½ mg. It must be confessed that disagreeable by-effects were sometimes seen with them.

Another group of hypnotics was the aldehyde group. They acted promptly, but their effects soon passed off. The chief representative of this group was paraldehyde, which was given in doses of 3 to 4 gm. It was almost as reliable but not so dangerous as veronal and trional. The danger of paraldehyde was much exaggerated. The speaker had seen a case in which the "kolosalen" dose of 18 gm. was given by mistake, in which complete recovery took place after a prolonged sleep. One drawback was the disagreeable taste of the medicine; this could, however, be almost covered by mixing it with red wine. As its effects were not lasting, it could not be given to patients requiring a lengthened sleep.

Chloral hydrate and its allied substances were near approaches to the foregoing. He would like to expunge the former from the list of hypnotics, as it had a very injurious effect on the stomach, intestines and heart. Of the allied substances, chloralamid had proved its value; from effective doses of 3 to 4 gm. he had never seen any ill effects. He did not give isopral so willingly; even in doses of 1.5 gm. it had a bad effect on the heart. It had, however, the great advantage of rapid action, acting in from 10 to 30 minutes. Nearly allied to this was chloracetone. Dormiol was commendable; up to 0.5 to 1.5 gm. it acted rapidly, and had but little action on the heart.

Another group was the sulphones, sulphonal, and trional, whilst tetronal had proved a failure. The chief advantage of trional was the prolonged sleep that followed its administration. It was a disadvantage that the sleep had often to be waited for, so that no dependence could be placed on it as regarded time; it could not be used, therefore, for patients who slept with difficulty. After doses of 1.5 gm. he had scarcely ever seen any bad effects, especially none on the heart. In France it was often given in conjunction with paraldehyde, and in this combination it acted well and rapidly. A combination of several hypnotics was generally of great service. Very distinct from these chemically was veronal, but its action was very similar. From his experiences with the drug he could only recommend it; it acted well, but very slowly, and the heaviness set up by it frequently lasted all the next day; the dose was from 0.5 to 1.5 gm. A great deal had been published regarding the dangers of veronal, but he had never seen anything of them, certainly none as regarded the heart or kidneys; even in serious cardiac disease he had never seen any injurious effects; death had not followed doses of 8 to 10 gm. The erythema that sometimes followed even moderate doses was rather disagreeable than dangerous.

Trionalosis and veronalosis might follow the prolonged use of these drugs. The remedies should be varied, therefore, but a change from one of them to the other was of no use. Their clinical relationship was also shown in the fact that when one lost its effect through repetition, the effect of the other was lost at the same time.

Out of the urethane group, urethane, and especially hedonal, were to be named. Urethane was no longer worth mentioning; hedonal, on the other hand, was a useful medicine, especially as a temporary exchange with another. It was given in doses of from 1 to 3 gm. and more. It was not as reliable as trional and veronal, but patients got accustomed to it less readily, and it exercised no injurious by-effects.

After veronal, proponal was also to be mentioned. It did not act so slowly as that, in 1½ to 2 hours, but in about one-third of that time, but it was not as reliable as veronal, and it did not, like veronal, act into the next day. In large doses there was no little danger; more than 0.5 gm. should never be given for a dose. As the effective dose was from 0.3 to 0.4 gm., there was very litle margin between the effective dose and one that was dangerous.

In conclusion, he recommended, if narcotics had to be given, that the changes should be rung frequently. The injurious effects that had been reported were often caused by one drug being continued too long. Combinations of drugs were also advisable; by making use of these, custom did not stale so rapidly, disagreeable symptoms were avoided, such as had made their appearance when the dose of the individual drug had been carried too high.

AUSTRIA.

Vienna, March 8th, 1908.

METASTASIS.

At the Gesellschaft, Eiselsberg brought forward a case he had operated on in 1902 by removing a part of the lower jaw for sarcoma. The patient is now 33 years of age with a large tumour behind the right ear, probably a metastatic result of the former operation. A small swelling commenced four years ago, and has gone on gradually increasing till it now reached the size of another head. The Röntgen rays show it to be closely bound up with the bones of the cranium. Both optic nerves are greatly atrophied from congestion, while the vestibular affection of the ear is convincing proof that further operation would be useless.

The Calmette Reaction.

Pirquet showed several children, healthy and strong, who responded to the ophthalmo-tuberculin reaction as practised by Calmette, who drops a small quantity of a diluted tuberculin into the sac of the conjunctiva, which produces a rapid reddening of the membrane in a short time in tubercular subjects. Calmette recommends a precipitate of tuberculin with alcohol after it has been diluted with 20 parts of water, but the "old tuberculin" diluted to a 5 per cent. solution will also act efficiently.

Three to six hours after dropping into the eye, the conjunctiva becomes red, particularly the caruncula lacrymalis and lower lid, which is described as the first stage of the reaction; when the conjunctiva of the bulb is involved, it has reached the second stage; and when exudation appears the third stage. This reddening usually disappears in two or three days. This operation is not without its dangers, as some experimenters have met with conjunctivitis lymphatica as a sequela.

Escherisch thought Pirquet's cutaneous reaction was a much easier and more satisfactory test than Calmette's.

Gastric Carcinoma.

Gohn showed an anatomical preparation from a boy, æt. 13, where the lung had been eaten away by a carcinomatous growth in the stomach. The invasion of the lung seems to have been a year old, as an operation was performed about that time for pyloric stenosis, and jejunostomy performed. Shortly after the operation pneumonia set in. At the post-mortem it was observed that the morbid process had extended from the small curvature and pylorus to the diaphragm, through which it entered the lung.

Adipose Diarrhœa.

Escherisch showed a child ten weeks old at the breast that had suffered from fatty diarrhœa and a severe form of seborrhœa. By reducing the quantity of fat in the milk the child speedily recovered. The milk was first drawn from the breast, put in a centrifuge, and all the fat extracted. Leiner recorded several cases that had come under his own observation, which he had treated successfully with that highly lauded article—buttermilk. Swoboda thought it was sufficient to stimulate the cutaneous surface, which he had always practised with success.

The Relation of Mammæ and Genitals.

Foges related his experiments with animals in extirpating the ovaries before the animal came to maturity. After the operation the mammary glands became stationary or hypertrophied. On the other hand when the uterus was removed, the ovaries and the mammæ remained normal. He concluded that the secretion of the ovaries was necessary to produce the reflex action for the growth of the mammary gland, but not necessarily for the functional production of milk, as the milk could be extracted even in larger quantities after the ovaries had been removed. Halbin said he had brought this subject before the meeting three years ago to show that the placenta had some relationship with the increase of the breast, and that the functional activity of the placenta was adverse to milk secretion, but immediately after its expulsion the lactic function commenced. He also affirmed that the active ovaries inhibited the breast secretion, which now agrees with Foges' experiments that removal of the ovaries promotes the secretion. He can sympathise with Foges' so-called lactation amenorrhœa as a consequence of inactive ovaries, as he was the first to promulgate this hypothesis.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

LOCAL GOVERNMENT INQUIRY AT RUCHILL FEVER HOSPITAL.—A lengthy report has been presented to the Local Government Board by Sheriff Crawford, Prof. Harvey Littlejohn, and Mr. Murray, who recently held an inquiry into the state of affairs existing in this hospital. They report that they are satisfied that the complaints of overcrowding and under-staffing have been substantiated, and that the friction within the staff of the hospital can be traced to these two facts. In 1907 there was a great strain thrown on the hospital by the prevalence of diphtheria, whooping-cough, cerebro-spinal fever and measles. It is not possible to separate the questions of overcrowding and under-staffing, because the management of the hospital has always proceeded on the principle that in times of stress the standard number of patients may be considerably exceeded without danger. The Commissioners point out, however, that cubic space cannot be reduced *pari passu* with age, and that 2,000 cubic feet is not an extravagant allowance for such diseases as diphtheria or enteric, while in measles and whooping-cough the prevalance of broncho-pneumonia is largely influenced by ventilation and cubic space. Again, children require as much, or even more, attention than adults. There is evidence of excessive overcrowding at least in the whooping-cough, cerebro-spinal fever, and measles wards. In May there were 51 patients, adults, and children, 30 of them unconscious, in a ward constructed for 15 beds. In December there were 74 children with measles, many of them suffering from broncho-pneumonia, in a ward of the same size, while in Ward 7, which is a small ward, on one day at least there were 62 patients, causing the air to be polluted and offensive, notwithstanding the excellent ventilation. This overcrowding meant that the floor area was so much obstructed by beds and cots that the nurses could not work without great difficulty; it meant that two children lay in one bed; it made the number of nurses inadequate, with the result that some of the children lay unattended for hours. It was impossible to feed so many at the proper times, and proper cleanliness was impossible. Discussing the question of under-staffing, and the friction that arose in consequence, the report fully admits that the matron had difficulty in getting suitable nurses. As the strain on the hospital increased, the insufficiency of the staff became more and more acutely felt towards the end of 1907. During the absence of the superintendent in September, one of the assistant physicians applied to the matron for extra nurses, and raised the question of the adequacy of the staff in view of the approaching winter. The matron, however, declined to admit that the assistant physicians had aught to do with the staffing of the wards. The Commissioners regard the action of the assistant physicians in going to the matron as an error; they should have waited until next day, when the superintendent was expected home. In her resentment, however, the matron made an even more serious error. Instead of waiting to complain to the superintendent, she went into the city and complained to the Convener of the Hospital Committee. After a conference between the Convener, matron, and medical superintendent, it was agreed that the matron's authority must be supported, and that she should reprimand the nurses, and Dr. Johnstone the assistant physicians. The report goes on to say that there is no evidence that there was any conspiracy on the part of the nurses against Miss Landle, the matron; that she herself was harassed, and was extremely angry, and forgot that she was addressing women who were themselves overtaxed. Dr. Johnstone received the assistant physicians' claim to be consulted about the nursing staff unfavourably, and, in consequence, they appealed to the Hospitals Committee. A truce was patched up, but ultimately the matrons and assistant physicians were not on speaking terms. It became impossible for both to remain in hospital together, and finally the assistant physicians were dismissed. The Commissioners consider that all this unfortunate friction could have been avoided had the superintendent dealt firmly with the state of affairs existing at his return on September 25th. Had he done so, neither the matron's address to the nurses, which created so much ill-feeling, nor the assistant physicians' dealings with the Hospital Committee, which in the long run led to their dismissal, need have occurred. As regards the general question of under-staffing, Dr. Johnstone did not sufficiently realise his responsibilities and duty. In the opinion of the Commissioners, the responsibility for the overcrowding lies with the Medical Officer of Health and the superintendent. During epidemics considerable relaxation of the usual rules as to numbers may be permitted, but at Ruchill the standards were not relaxed, but entirely discarded—the number of beds being multiplied by four, five, and even six. The Commissioners cannot accept Dr. Johnstone's view that his responsibility was limited to making the best distribution he could of patients sent in by the Medical Officer of Health; he ought to have said, "My hospital is full; the wards are full; and I have no others into which I can put additional patients." He might have been overruled, but more likely the Medical Officer of Health would have listened to his representations. On the other hand, Dr. Chalmers had, in the daily returns, means of knowing of the overcrowding. No responsibility attaches to the Hospital Committee, as the subject was not brought under their notice. In conclusion, the reporters state the mistakes made were not due to wilful negligence; that the health of the patients was not seriously affected, and the death rate no more than normal. In a covering letter the Local Government Board agree generally with the findings of the report. They state that, "Apart from the question of administrative responsibility, and of that of the procedure adopted by the resident medical officers, the allegations in question [of the residents] have turned out, on the whole, to be well founded." After reading the whole report, the general conclusion seems to be that the resident medical officers, though they placed themselves in the wrong and rendered their position untenable by mistaken tactics, and in particular by claiming the right to be consulted about the staffing of the wards, have yet done the city of Glasgow good service by exposing an inefficiency in the administration of the Ruchill Hospital which could not have continued without serious disaster. It is true that both the Hospitals Committee and the reporters amply recognise that their dismissal carries with it no imputation of professional blameworthiness—they were rather too zealous servants; but should any of the gentlemen in question desire to continue in the line of professional work they have begun, it is to be hoped that the health authorities in Glasgow will offer them reinstatement in office as vacancies may occur.

BELFAST.

PUBLIC HEALTH.—The number of cases of cerebro-spinal meningitis notified each week continues rather higher than for some months past, but shows no signs of alarming increase. Four cases were notified last week, and eight the week before, and there are at present 23 cases under treatment in the Purdysburn Fever Hospital. In the same hospital there are eight cases of typhus, showing that that disease is rather more prevalent than usual. The death-rate of the city, after touching 30, has fallen to 22.8.—The first report on the working of the Notification of Births Act was given by the Medical Superintendent Officer of Health at a meeting of the Public Health Committee last week. He stated that since the Act came into force 622 births had been notified. Of these 195 had been visited once, and 48 of these were notified to the Women's National Health Association for their health visitors to look after.

SOCIETY FOR PROVIDING NURSES FOR THE SICK POOR.—The annual meeting of this excellent society was held on the 6th inst. under the presidency of the Lord Mayor. The report showed that 1,291 cases had been attended, and 33,909 visits paid. The total number of cases was 168 in excess of the previous year, and the number sent by doctors was 154 in excess, a strong testimony to the value of the work done by the society. A large number of convalescent patients were sent to the seaside, and help in the form of clothes, meat, and milk, and medicine given to many destitute or deserving cases. Dr. R. J. Johnstone, who spoke at the meeting, warmly commended the work of the Society.

LETTERS TO THE EDITOR.

THE PHYSIOLOGICAL IMPORTANCE OF THE CALCIUM SALTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I feel sure you will allow me space in THE MEDICAL PRESS AND CIRCULAR to make a few comments upon the account of my paper read before the Liverpool Medical Institution, and the subsequent discussion, as reported in your issue of February 26th, page 239.

At first I felt almost tempted to congratulate Dr. Gordon Little on *his* paper, for the brief summary of *my* remarks (which I deem quite sufficient) hardly does justice to his criticism.

On thinking the matter over, however, I believe it was *I* who read the paper on experimental work done by myself, and that Dr. Gordon Little very kindly added considerable interest to the meeting by a very able and carefully prepared speech, which was only spoilt by certain remarks which were, I think, unnecessary and unjustifiable; but those present considered, so I am told, that in my reply I satisfactorily answered all his objections, if the other speakers had not already done so, for he was the first of those reported to speak.

In the circumstances I was somewhat surprised to see, in the published account of the proceedings, not only an amended summary of his remarks, but also a reply to my reply! This seems to me hardly "playing the game," even supposing he does wish to depreciate, for reasons best known to himself, the value of my method and work, with which he is so little acquainted practically.

It is not my intention to carry on a controversy with Dr. Gordon Little or anyone else at present, as I hope that my paper will be published *in extenso* in due time, when others interested will be able to judge for themselves; but I think I can claim at least the right to reply to Dr. Gordon Little's remarks, as many men about the country who have taken the trouble to write to me, or to come long distances to learn the method and see the work, may be unduly influenced by his statements, not having heard my paper or reply.

Dr. Gordon Little has never, so far as I know, even seen the method of calcium estimation in blood carried out, nor has he examined the accuracy of it which he so candidly criticised.

If he had done me the honour to bestow the same attention upon my paper as he evidently did upon the synopsis issued beforehand, he would have gathered :—

(1) That I definitely stated that only the ionised calcium was precipitated by my method, but that this calcium was probably the most important as far as rapid tissue changes were concerned.

(2) That I long ago gave up the comparative standard—blood with aqueous solution—mentioned in my original preliminary paper. (*a*) I now only speak of the blood-index, and acknowledge that, strictly speaking, each different solution should be worked out independently. (Further, his objection to an "index" at all, because of the variations, is ridiculous on the face of it. It would be useless to have an "index" if it did *not* vary. Again, the standard blood-index *has* been founded on many hundred blood examinations.)

(3) That the deduction he draws from my observations on menstruating women was drawn by me and mentioned. (How can *he* be so rash, in the face of his remarks, as to draw conclusions based on the method?)

(4) That I did ample justice in my paper to other workers, especially Ringer. (Consequently, it was particularly gratifying to receive myself the appreciation of such an eminent authority on calcium salts in disease as Sir James Barr, and of the other gentlemen who spoke.)

The long discourse on Mörner's paper (*b*) is quite new. In his speech Dr. Gordon Little stated that "someone had, as far back as 1870, shown that after the removal of the calcium salts coagulation still occurred in gelatin." In my reply I said that I doubted if in 1870 it was known that there was calcium in gelatin, and certainly nothing could have been known of its effect upon the setting thereof. Even if its presence were known then, I said I saw no reason to suppose that all the calcium could have been removed in those days, since it is impossible, as far as I know, to do this in 1908 without destroying the gelatin. I see now that Mörner's paper of 1899 is given! This paper deals mainly with the action of *neutral salts* upon gelatin, but as I used oxalic acid (not ammonium oxalate or any neutral salt, as might also have been gathered from my paper), I fail to see that Dr. Gordon Little has made his position any better in this matter by shifting his ground.

But this is not all. A careful examination of Mörner's paper reveals the fact that be specifically states in the text, and in a long footnote, that he has been *unable* to get ash-free gelatin (confirming my statement). His remarks simply refer to ash-rich gelatin, and gelatin from which as much of the "salt" contents as possible has been removed. My contention is thus entirely confirmed. The technique for preventing the coagulation of gelatin by precipitating the calcium will be published with the rest of the paper.

I have no wish to make such an enthusiastic metabolist as Dr. Gordon Little an adversary to my method and work, especially as I believe he has allowed himself to be influenced by others. I hope rather that he will test my statements himself, and bear in mind that I do not intend to invade the field of general metabolism by giving out these incidental observations. Being only a gynæcologist, I am endeavouring to clear up the physiology of my special branch, for, so far, the chemists and physiologists (on whom Dr. Gordon Little thinks the work should devolve) have been unable to find satisfactory solutions to many of the problems involved.

My paper read before the Liverpool Medical Institution was, in fact, a programme for those interested in general metabolism, and founded, as I say, on incidental observations which I could not neglect, and consequently feel constrained to defend.

I am, Sir, yours truly,
W. BLAIR BELL.

Liverpool, March 2nd, 1908.

CHRISTIAN SCIENCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Sewill has so frankly relapsed, in his last letter, from any attempt at argument to the easier method of abusing the plaintiff's attorney, that I am perfectly willing to admit that there is nothing to be gained by continuing the discussion with him. There are, however, one or two points in his last letter I should like to make clear.

He says that with my theology "we have little to

(*a*) "Brit. Med. Journ.," April 20th, 1907, p. 923.
(*b*) Zeit. f. Physiol. Chemie. Band, 28, p. 471.

do." That is a position I am quite willing to accept, but it is an extraordinary one from a gentleman who took the trouble originally to write a letter to your paper of 42 lines, out of which 32 were devoted to what he intended to be an exposure of that theology.

Then he says I admit there is such a thing as incurable disease. Of course, I admitted nothing of the sort; indeed, that all disease is curable is so well known to be the standpoint of Christian Science, I did not think it necessary to elaborate the statement. In the passage to which he refers I was not dealing with the Christian Science view of the case, but with the medical. The medical evidence was to the effect that the case was incurable when it passed under Christian Science treatment. I used this evidence, *inter alia*, simply to prove that Mr. Sewill's contention that the patient had suffered by his case being transferred to Christian Science was untenable. I agree with the statement contained in Mr. Sewill's first letter that God is omnipotent, and consequently I should not dream of limiting the power of God by representing any disease as incurable.

Mr. Sewill talks of the Christian Scientist's ignorance of true science, but it is always a mistake to assume that those who differ from you are more ignorant than you are yourself. As a matter of fact, Mr. Sewill is endeavouring to establish orthodoxy in natural science just as orthodoxy has been established in religion. The idea is not a new one. The mediæval Church made this attempt, and for a time succeeded in it. But, as one of the greatest victims of the attempt is reputed to have said, the world moves, and the attempt broke down.

True science is undoubtedly the effort to demonstrate absolute truth. This is presumably what St. Paul meant in speaking of the *epignosis tou theou*, the full, exact—that is, scientific—knowledge of God. This is what Thomas Aquinas—who, Huxley once hazarded the suggestion, was perhaps the subtlest of all the world's great thinkers, meant when he said that the only absolute science was the science of theology—that is, of the Word of God—while all else was merely relative; and this is what Mrs. Eddy means in writing on page 341 of "Science and Health":—"Sneers at the application of the word Science to Christianity cannot prevent that from being scientific which is based on Divine principle, demonstrated according to a given rule, and subjected to proof."

Mr. Sewill may, as I have already pointed out, maintain that science applies only to secondary causes, and that primary causes are in the category of unprovable assumptions; but I repeat that that is only begging the question, and that so long as you insist on such conditions you will obviously be bound by them. It is very much the frame of mind of the early ecclesiastical thinkers, who insisted that the earth was stationary, and that the sun rose and set. But Mr. Sewill himself speaks of "Divine Providence, the Omnipotent and Omniscient." What, on his own showing, therefore, could be more scientific than the effort to know this aright, and what is this knowledge but the *epignosis tou theou?*—the knowledge, in a word, of the Truth which Jesus said would make men free?

I am, Sir, yours truly,
FREDERICK DIXON.

THE PHARMACISTS AND QUACK MEDICINES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If the profession which you so ably represent is not duly grateful for the service you are performing by your campaign against quackery, I can, I think, safely assure you that your services are being thoroughly appreciated by qualified pharmaceutical chemists. Every respectable man in our calling will subscribe to the view of this question put forth a few months ago in the *Pharmaceutical Journal* by a well-known writer who has made the subject largely his own. I would like to epitomise and make as my own his statements; they embody the sentiments of us all. The quack medicine trade is hateful to every qualified chemist, who, under present conditions, finds himself compelled to take part in it. From the business point of view, it is almost impossible for the average man in the trade to refuse to participate in a traffic which he knows to be at once fraudulent and cruel. He knows that the vast majority of secret remedies are, when least harmful, mere worthless trash; he knows what is the harm that results from reliance upon bogus cures when organic disease exists; he knows the murderous results of some of them when potent drugs of the wrong kinds are contained in them, such as anodynes and narcotics, which mask symptoms instead of affecting the real disease. Educated chemists must all, as I do, surely detest the quack medicine trade, and would welcome any legislation to check it. From the merely business point of view it seems to me evident that if the quack drug trade were curtailed, the increased demand for legitimate medicines would far outweigh any loss arising from the altered state of the trade. On selfish, not less than on moral grounds, it seems the duty of pharmaceutical chemists to back you up in your fight against quackery; and I hope to see before long some active manifestation of the feelings which, I believe, are sincerely and widely prevalent. There are, I am sure, obvious reasons why I should prefer to withhold my name and subscribe myself,

Yours truly,
M.P.S.

London, W., March 6th, 1908.

DE LAVONDO NEONATORUM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nowadays, if one preach anything but ceaseless lavations, he is dubbed an apostle of filth; yet Aristotle, the wisest of our race, proclaims that wisdom lies in the mean, and not in the extreme, and Bacon teaches us that we are often the slaves of a word like "filth."

I will invoke a third great name to keep me in countenance, and recount that Carlyle tells us it is better to be dubbed a fool because one does not follow a beaten track than to be called wise for following the crowd.

Thus fortified, I assert that the washing of new-born infants is a superstition of the cruellest character, and is responsible for the death, by bronchitis or otherwise, of very many of them.

Kind Nature provides the child with an emollient, unctuous armour—a most admirable shield for its cutaneous nerve endings against the sudden shock of the chill, extra-uterine world—and, instead of allowing it to discharge its beneficent function, and be shed in due course of time, we insist on flaying the infant of it, despite its howls of agony, and inflict awful torture by washing the raw and quivering flesh.

Seriously, I suggest that the practice is cruel and unscientific, and should be stopped.

I am, Sir, yours truly,
J. C. MCWALTER, M.D.Brux., D.P.H.

Dublin, February 29th, 1908.

VACCINATION AND THE MEDICAL PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Alfred S. Gubb, M.D., of Algiers, does not deny my statement that all those members of the medical profession who have studied the subject, and that they are legion, condemn the practice of vaccination, but he says it hardly admits of proof. The thing is clearly proved by the number of medical speakers and writers against it in this and every country where it is practised. It is also proven in another way, viz., by the fact that those medical men who do advocate it have never studied it, and this is proven by the fact of their total ignorance respecting it. From a medical point of view, they know nothing whatever about it, not even enough to enable them to agree on any single one of its aspects, and their method of endeavouring to bolster it up is only by the resort to cooked and false statistics.

Where, I would like to ask Dr. Gubb, are the old time remedies of bleeding, blistering, smallpox inoculating, etc., in daily use as recognised "therapeutical procedures," as he declares them to be? In this country, at any rate, the last named "therapeutical procedure" is a highly penal offence.

For a medical or any other man to compare a purposive blood poisoning like vaccination to "trimming one's nails or picking one's teeth," as does Dr. Gubb, is to "expose himself to the imputation of ignorance if not rank stupidity." No one is compelled, as an alternative to fine and imprisonment, to trim their nails or pick their teeth.

Dr. Gubb is simply "trading on our gullibility" when he asks us to accept, without adducing one particle of evidence in support, such an extravagant statement as that "vaccination has saved, and is saving, millions from a terrible disease."

Dr. Gubb says the "Arabs greedily welcome vaccination now that they have had a few object lessons on the subject." Well, there are those who after having a few object lessons of the wonderful efficacy of dispersing an eclipse of the sun by the beating of tomtoms and blowing of instruments, greedily welcome these remedies. And this is about on a par with the Arabs' welcome of the vaccination superstition.

I am, Sir, yours truly,
J. West.
Bradford-on-Avon, March 3rd, 1908.

CYLLIN AND CRESYLIC ACID.

To the Editor of The Medical Press and Circular.

Sir,—An important caution to medical practitioners is given by Dr. David Sommerville in the *British Medical Journal*, February 1st, 1908, page 300, in regard to the substitution of cresylic acid for the preparation known as cyllin. He writes:—

"In the article on cresylic acid, the British Pharmaceutical Codex states, at p. 15, that cresylic acid enters into the composition of a number of proprietary disinfectants, such as cyllin, creolin, lysol, etc., and that a typical preparation of this class is liquor cresolis compositus, whose composition is described on page 613 as consisting of:—Cresylic acid by weight, 50; linseed oil, 35; caustic potash, 8; alcohol, 4; distilled water to 100. From work that I have done on the chemical and germicidal properties of cyllin during the last five years, I have no hesitation in saying that this statement is at once misleading and dangerous. Cyllin, as prepared for medical practitioners and pharmacists, contains no cresylic acid. As concerns disinfection in medical or surgical practice, the above substitute cannot be used without liability to disastrous results. The Rideal-Walker Co-efficient of cyllin medical is 20.0; the Rideal-Walker co-efficient of the above substitution product is 2.5."

As this matter must be of considerable interest to your readers, we should be grateful if you could find space to refer to it in an early issue.

I am, Sir, yours truly,
(For Jeyes' Sanitary Compounds, Ltd.)
J. T. Ainslie Walker,
Managing Director.

February 28th, 1908.

OBITUARY.

SIR ALFRED COOPER, F.R.C.S.

A distinguished London surgeon has passed away in the person of Sir Alfred Cooper, who died at Mentone on Tuesday, the 3rd inst., after having attained the age of 70 years. For some years past he had retired from the active practice of his profession owing to the protracted illness which has just terminated fatally. He was educated at the school of St. Bartholomew's Hospital, and became a member of the Royal College of Surgeons of England in 1861, and Fellow in 1870, having previously obtained the Fellowship of the Edinburgh College. He was for many years one of the Surgeons to the Lock Hospital, a circumstance which served to determine the chief direction of his professional work. His best known works are those on syphilis, upon which he was a recognised authority. He was also at different times Surgeon to St. Mark's and to the West London Hospitals. He was appointed Surgeon-in-Ordinary to the late Duke of Saxe-Coburg and Gotha (Duke of Edinburgh), and received various marks of distinction from Russian and German medical bodies. Sir Alfred Cooper was also Surgeon to the Inns of Court Royal Volunteers, and to the Duke of York's Loyal Suffolk Hussars; and was the author of important works upon the department of surgery in which he chiefly practised. He had been Vice-President of the Royal College of Surgeons, and was a member of many of the medical and scientific societies. Sir Alfred married, in 1882, Lady Agnes Duff, daughter of the fifth Earl of Fife, and he received the honour of knighthood in 1902.

EDWARD DILLON MAPOTHER, M.D., R.U.I., F.R.C.S.I.

We regret to announce the death of Dr. Edward Dillon Mapother, on the 3rd inst., at his London house in Welbeck Street. The more active period of his professional life was passed in Dublin, where he enjoyed a good deal of social and professional distinction. He graduated as M.D. at the Royal University of Ireland in 1857, and took the Fellowship of the Royal College of Surgeons of Ireland in 1862. He was Surgeon to St. Vincent's Hospital, and to St. Joseph's Hospital for Children, in Dublin. He also filled the posts of Professor of and Examiner in Physiology to the college, in which he served the office of President, was Examiner in Surgery to the Queen's University of Ireland, and Surgeon-in-Ordinary to the Lord Lieutenant. He was the author of a text-book on Physiology which passed through three editions, of numerous works on various questions of medicine and of hygiene, and of numerous papers in the medical journals and in the late Sir Richard Quain's "Dictionary of Medicine," in which he wrote the chief articles on the various forms of skin disease. In London he was chiefly known in association with dermatological work.

REVIEWS OF BOOKS.

NISBET'S MEDICAL DIRECTORY. (*a*)

The appearance of a new medical directory is a somewhat notable event in the medical world. The present volume is issued on a plan that differs in treatment from existing and previous publications of the kind. Matter has been edited strictly with a view of keeping down space, and the result is a royal octavo volume of about one and a half inches in thickness. Initials are given in place of full Christian names, and as a rule not more than one appointment and one publication are inserted. Another novel feature is that the names are given in alphabetical order for the whole kingdom, after the manner adopted by the official *Medical Register*. The book is divided into two parts, the first containing a full directory of medical men, while the second is a local list. The price is 7s. 6d., a figure that justifies the publishers' claim that theirs is the cheapest medical directory published. It certainly does not err on the side of diffuseness, which is something to say in these modern days of rush and hurry.

ON TREATMENT. (*b*)

It is obvious that of any class of medical students only a small percentage can become specialists or consultants, and still the training they receive is almost entirely in the hands of specialists and consultants, and in many ways more fitted to produce specialists than general practitioners. For the majority of men an "assistancy" is the only "post-graduate course" which will teach them to corelate the ideas gained in hospital to the exigencies of general practice. To such men a book with the title of Dr. Harry Campbell's latest work, "On Treatment," will be especially welcome. If there is at first some sense

---

(*a*) "Nisbet's Medical Directory." London: James Nisbet and Co. 1908. Price 7s. 6d.

(*b*) "On Treatment." By Harry Campbell, M.D., B.S., F.R.C.P. (Demy 8vo, pp. 429). London: Baillière, Tindall, and Cox, 1907. Price 5s.

of disappointment at the absence of detail in the book, no medical man will read it without a feeling of refreshment and real gain. Dr. Campbell's writing abounds in that higher power of common sense which may properly be called wisdom. He touches with no gentle finger the weaknesses of medical education, and points out quite frankly the many items in the student's load of acquired information which are entirely a useless burden; but his advice is no encouragement to the "slacker"; he is told in the same breath what knowledge to acquire in double measure. The chapter on Rationalism and Empiricism is, perhaps, the most interesting in the book; and Dr. Campbell makes an important point when he reminds us that a form of treatment devised by a process of pure reasoning becomes a routine or empirical treatment in the hands of those who use it simply on the authority of the discoverer. It requires some courage nowadays to write, "Concerning treatment by drugs, I strongly advise the physician to give them on the routine principle." But Dr. Campbell makes no statement without giving his reasons, and his arguments, even if not always convincing, are always interesting.

THE PROLONGATION OF LIFE (*a*)

THE critics of Professor Metchnikoff's book on "The Nature of Man" have, at any rate, one point on which they have good reason to congratulate themselves. They have stimulated the distinguished author to reply in book form to their criticisms, and to bring together a number of studies bearing on subjects allied to those previously treated. The result is the present fascinating volume on "The Prolongation of Life." As might be expected from such a begetting, the subjects dealt with are very various, but there is a continuous thread of thought connecting the different sections. Perhaps the most interesting point about M. Metchnikoff's views as a philosopher—and it is, of course, as a philosopher rather than as a man of science we have to deal with him here—is the fact that his optimism is purely naturalistic and at the same time individualist. It has always been regarded as a reproach to the philosophy which has sprung from natural science that it tended toward pessimism in its outlook. Thus, the materialism which, not unnaturally, though hardly logically, grew out of the militant agnosticism of Huxley and Tyndall, has been singularly unattractive.

M. Metchnikoff, however, is a thoroughgoing optimist, though one may have half a suspicion that his optimism is at least as much a result of his buoyant temperament as of his science—that it is, in fact, quite as much subjective as objective. Though it may be, therefore, failing in universality, it is none the less communicable, and no more exhilarating task can be undertaken than the study of M. Metchnikoff's views.

His ideal is the condition he names "orthobiosis," which he describes as "the development of the human life so that it passes through a long period of old age in active and vigorous health, leading to the final period in which there shall be present a sense of satiety of life, and a wish for death." This is probably the ideal of a great many healthy men and women, but nevertheless the author assumes, rather than establishes it, and he can hardly escape the objection that the foundation of his doctrine is rather in individual and personal psychology than in the necessary elements of the rational mind. From another standpoint it may, of course, be said that no ideal is satisfactory which does not include the prospect of a future life.

M. Metchnikoff is proud, and rightly so, of the great strides science has made in recent generations. He believes that the work preventive medicine has already performed is only an earnest of what it will do in the future. He hopes that we may, in time, be able to rid humanity of all the diseases to which it is at present subject. It will be possible also to guard against the various accidents which constantly threaten us. When that era has arrived the only check to human life will be old age, with its natural death. M. Metchnikoff discusses the causes of senility, and argues in favour of the doctrine that the phagocytes, our greatest allies in younger life, turn on us as enemies in old age, and destroy our very vitals. Whence this revulsion? Can it be that the phagocytes are stimulated to this unnatural revolt by any toxin in the body? M. Metchnikoff suggests that, whatever the mechanism may be, intestinal putrefaction, with the consequent absorption of toxins, is a potent factor in the production of senile decay. He argues, with a fair amount of evidence, for some association between a large intestine and shortness of life, and he maintains that in man the large intestine is not only a useless but a hurtful organ. He mentions cases where its absence was followed by no ill effects. As we can hardly hope to rid ourselves of the large intestine, M. Metchnikoff discusses the means by which we may neutralise its injurious influence. If the large intestine were sterile, it would be harmless. Now, it is possible practically to deprive it of its putrefactive flora by introducing large numbers of an organism whose products are fatal to them—the lactic acid bacillus. This can be done either by drinking large quantities of sour milk or by injection of pure cultures of the lactic acid bacillus. Rendering the large intestine innocuous by such means, we may hope, by paying proper attention to general and personal hygiene, to approach more nearly to orthobiosis.

We have developed one of the main ideas in this remarkable book to the exclusion of others. But the reader will be almost startled by the variety of topics with which M. Metchnikoff deals. In addition to studies of senility and longevity, we have an investigation of natural death among plants, animals, and men; a discussion on the psychical rudiments in man; a section on the history of social animals; studies on pessimism and optimism, and on science and morality; and a section of acute criticism of Goethe as man and poet.

On many points of theory and conduct one may differ with M. Metchnikoff's teaching in this book. His logic is faulty, and his conclusions more hypothetical than he admits. In every point, however, one must respect his outspoken honesty and sincerity. He touches on many topics—he has adorned them all.

To Dr. Chalmers Mitchell we are indebted for an English text which rarely betrays that it is a translation. There is a strange blunder on p. 143, where the average annual mortality appears to have been multiplied by ten.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

EDWARD ARNOLD (London).
  The Chemical Basis of Pharmacology. By Francis Francis, D.Sc., Ph.D., and J. M. Fortescue-Brickdale, M.A., M.D.Oxon. Pp. 372. Price 14s. net.

BAILLIERE, TINDALL AND COX (London).
  The Pocket Anatomy. Sixth Edition. Revised and Edited by C. H. Fagge, M.B., M.S.Lond., F.R.C.S. Thirtieth thousand. Pp. 270. Price 3s. 6d. net.
  Aids to Surgery. By Joseph Cunning, M.B. B.S., F.R.C.S.Eng. Second Edition. Pp. 404. Price, Cloth, 4s. net., Paper, 3s. 6d. net.
  The Spectroscope: Its Uses in General Analytical Chemistry. An Intermediate Text-Book for Practical Chemists. By T. Thorne Baker, F.C.S., F.R.P.S. Illustrated. Pp. 130. Price 5s. net.
  Hernia: Its Etiology, Symptoms and Treatment. By W. McAdam Eccles, M.S.Lond., F.R.C.S.Eng. Third Edition. Illustrated. Pp. 234. Price 7s. 6d. net.
  Protozoa and Disease. Comprising Sections on the Causation of Smallpox, Syphilis, and Cancer. By J. Jackson Clarke, M.B.Lond., F.R.C.S. Part II. Illustrated. Pp. 138. Price 7s. 6d. net.
  Minor Maladies and their Treatment. By Leonard Williams, M.D., M.R.C.P. Second Edition, revised and enlarged. Pp. 404. Price 5s. net.

JOHN BALE, SONS AND DANIELSSON, LTD. (London).
  The Pyonex: Its Theory and Practice. By W. B. Rule, M.R.C.S., L.R.C.P. Pp. 572. Price 12s. 6d. net.

BALLANTYNE AND CO., LTD. (London).
  Egypt, and How to See it. Illustrated by A. C. Lamplough. Pp. 208. Price 2s. 6d.

CAMBRIDGE UNIVERSITY PRESS (London).
  The Journal of Hygiene. Edited by George H. F. Nuttall, M.D., Ph.D., etc., etc. Vol 7. No. 6. December, 1907. Published Quarterly. Price 6s. net.

(*a*) "The Prolongation of Life: Optimistic Studies." By Elie Metchnikoff, Sub-Director of the Pasteur Institute. The English Translation edited by P. Chalmers Mitchell, M.A., D.Sc.Oxon., Hon. LL.D., F.R.S. London: William Heinemann. 1907. Price 12s. 6d. net.

The Caxton Publishing Co. (London).

The Edinburgh Stereoscopic Atlas of Obstetrics. Edited by G. F. Barbour Simpson, M.D., F.R.C.P.E., F.R.C.S.E., and Edward Burnet, B.A., M.B., Ch.B. With a preface by Prof. Sir Halliday Croom, M.D., etc., etc. Section 1. In four sections, each containing 25 subjects, with Descriptive Text. Price for the four sections, 84s. net.

Churchill J. and A. (London).

The Care of the Teeth in Public Elementary Schools. By C. Edward Wallis, M.R.C.S., L.R.C.P., L.D.S. Pp. 14. Price 1s. net.

A Manual of Prescribing for Students and Practitioners of Medicine. By C. R. Marshall, M.D. Pp. 373. Price 5s. net.

A Short Practice of Gynæcology. By Henry Jellett, B.A., M.D., B.Ch., B.A.O. (Dublin University): F.R.C.P.I. Third Edition, revised and enlarged, with 310 illustrations. Pp. 518. Price 12s. 6d. net.

Reports of the Society for the Study of Disease in Children. Vol. VII. Session of 1906-1907. Edited by George Carpenter, M.D. Pp. 305. Price 12s. 6d. net.

Lectures on Medical Jurisprudence and Toxicology, as delivered at the London Hospital. By Fred. J. Smith, M.A., M.D.Oxon., F.R.C.P., F.R.C.S. Second Edition. Pp. 463. Price 8s. 6d. net.

The Royal London Ophthalmic Hospital Reports. Edited by Wm. Lang, F.R.C.S.E. Vol. XVII. Part II. Jan., 1908. Price 5s. net

The Clarendon Press (Oxford).

Two Oxford Physiologists: Richard Lower, 1631 to 1691; John Mayow, 1643 to 1679. By Francis Gotch, M.A., D.Sc., F.R.S. Pp. 40. Price 1s. net.

The History of the Study of Medicine in the British Isles. By Norman Moore, M.D.Cantab. Illustrated. Pp. 202. Price 10s. 6d. net.

W. B. Clive (London).

School Hygiene. By Robert A. Lister, M.B., Ch.B., B.Sc., D.P.H. Pp. 360. Price 3s. 6d. net.

Henry Frowde and Hodder and Stoughton (London).

Rotunda Practical Midwifery. By E. Hastings Tweedy, M.D., F.R.C.P.I., and G. T. Wrench, M.D. Illustrated. Pp. 464. Price 16s. net.

Rotunda Midwifery for Nurses and Midwives. By G. T. Wrench, M.D. With Introduction by the Master of the Rotunda Hospital. Illustrated. Pp. 324. Price 6s. net.

Fevers in the Tropics. By Leonard Rogers, F.R.C.P., F.R.C.S., etc., etc. Illustrated. Pp. 343. Price 30s. net.

Life Insurance and General Practice. By E. M. Brockbank, M.D.Vict., F.R.C.P. Pp. 288. Price 7s. 6d. net.

The Garden City Association (London).

Town Planning in Theory and Practice. Papers and Speeches by Mr. Councillor Nettlefold, etc., etc. Pp. 72. Price 1s. net.

H. K. Lewis (London).

Studies in Blood Pressure: Physiological and Clinical. By George Oliver, M.D.Lond., F.R.C.P. Second Edition, enlarged. Pp. 255. Price 4s. net.

The Doctor in the Schools. By Hackworth Stuart, M.D.Lond., F.R.C.S.Edin., D.P.H.Cantab. Pp. 32. Price 1s. net.

An Essay upon Disease: Its Cause and Prevention. By G. E. Richmond, M.D., B.Sc., etc., etc. Pp. 96. Price 2s. net.

Diseases of the Nose and Throat. By Herbert Tilley, B.S.Lond., F.R.C.S.Eng. Illustrated. Pp. 539. Price 14s. net.

J. B. Lippincott and Co. (London).

International Clinics. A Quarterly. Edited by W. T. Longcope, M.D. Vol. IV. Seventeenth Series, 1907. Pp. 308.

Longmans, Green and Co. (London).

The Old Riddle and the Newest Answer. By John Gerrard, S.J., F.L.S. Fifth and cheaper edition. Pp. 121. Price 6d.

Proceedings of the Royal Society of Medicine. Edited by John Nachbar, M.A., M.D., under the direction of the Editorial Committee. Vol I. No. 2. Price 7s. 6d. net.

Proceedings of the Royal Society of Medicine. Vol I. No. 3. Price 7s. 6d. net.

Macmillan and Co., Ltd. (London)

"Confessio Medici." By the writer of "The Young People." Pp. 158. Price 3s. 6d. net.

Methuen and Co. (London).

Functional Nerve Diseases. By A. T. Schofield, M.D. Pp. 324. Price 7s. 6d. net.

Nisbet, James and Co., Ltd. (London).

Nisbet's Medical Directory, 1908. In two parts. Part I.: Directory of Medical Practitioners. Part II.: The Local Directory. Pp. 774. Price 7s. 6d. net.

W. B. Saunders Co. (London).

Treatise and Diseases of the Skin. By Henry W. Stelwagon, M.D., Ph.D. Fifth Edition, revised and illustrated. Pp. 1150. Price 25s. net.

Principles and Practice of Modern Otology. By John F. Barnhill, M.D., and E. de Wolfe Wales, B.S., M.D. Illustrated. Pp. 575. Price 24s. net.

A Text-Book of Diseases of the Nose and Throat. By D. Braden Kyle, A.M., M.D. Illustrated. Fourth Edition, revised and enlarged. Pp. 797. Price 18s. net.

Sidney Appleton (London).

A Text-Book of Treatment. By William Calwell, M.A., M.D., John Campbell, M.A., M.D., F.R.C.S.Eng., and Robert Campbell, B.A., M.B., F.R.C.S.Eng. Edited by R. J. Ferguson, M.D., F.R.C.S.Eng. Part 1: Obstetrics and Gynæcology, by John Campbell. Illustrated. Pp. 279. Price 10s. net.

The Sexual Instinct, its Use and Dangers as Affecting Heredity and Morals. By J. F. Scott, B.A., M.D., C.M. Second Edition, revised and enlarged. Pp. 473. Price 7s. 6d. net.

Gonorrhea, its Diagnosis and Treatment. By F. Baumann, Ph.D., M.D. Illustrated. Pp. 206. Price 6s. net.

A Text Book of Minor Surgery. By E. M. Foote, A.M., M.D. Illustrated. Pp. 752. Price 21s. net.

The Walter Scott Publishing Co. (London).

Euthetic Diseases (The Young Man's Peril). By. R. R. Rentoul. Pp. 39. Price 2s. 6d. net.

John Wright and Co. (Bristol).

First Aid to the Injured and Sick. An advanced Ambulance Handbook. By F. J. Warwick, B.A., M.B., etc., etc., and A. C. Tunstall, M.D., F.R.C.S.Ed. Fifth Edition, revised and enlarged. Pp. 252. Price 1s. net paper, 2s. net cloth.

The Experimental Prophylaxis of Syphilis. By Paul Maisonneuve. Translated by Fernand L. de Verteuil, M.B., M.R.C.S., L.R.C.P. Pp. 102. Price 4s. net.

LABORATORY NOTES.

A POUDRO-PENCIL.

Messrs. Christy have sent us a "Poudro," a little pencil-shaped article which they have devised for containing powder. The original idea was that it should be used by ladies to carry face powder about with them in the purse or in the satchel, but it seems likely to be useful to dentists and medical men, who have to continuously wash their hands. Any kind of powder required can be put in this ingenious little instrument, and extracted by pressing the point on to the back of the hand or wherever required.

ALEXINE.

This is a new preparation from the Paris laboratory of M. Chatelain, and is supplied in the form of pink granules which are slightly hygroscopic. These granules dissolve in water, producing a flesh-coloured opalescent solution, which has a pleasant taste and an acid reaction. The preparation is said to contain phosphoric acid in the free state, together with phosphates of iron and manganese, and our analysis shows this to be the composition. In its free condition, as presented in Alexine, it is claimed that the phosphoric acid is capable of entering into combination with those bases that need this acid, thus furnishing the organs with the means of forming the necessary phosphates. Further, we may add that the acidity of the preparation dissolves certain insoluble phosphates, and thus prevents the accumulation of these insoluble salts in places where they are not desired. The preparation is guaranteed to be accurately standardised, and to be absolutely harmless. The English agents for Alexine are Messrs. T. Christy and Co., Old Swan Lane, London.

STAPHYLOCOCCUS VACCINE.

Messrs. Parke, Davis, have sent in a sample of staphylococcus vaccine put up in convenient form. At the same time they convey the information that they have been appointed sole agents for the sale of the bacterial vaccines now being produced in the Inoculation Department, St. Mary's Hospital, under the direction of Sir Almroth Wright. Besides the staphylococcan vaccine, there are streptococcus, gonococcus, tubercle, and typhoid vaccines. The material is carefully put up in glass bulbs, and a note is added to the effect that typhoid vaccine should be used within three months of its preparation. The prices vary from 1s. 6d. to 5s. per bulb. Arguing from the authoritative source of these vaccines, it is safe to predict for them a large vogue amongst members of the medical profession. We are glad to see it specifically mentioned that the vaccines "are intended to be used solely under the direction of a medical practitioner."

BLACK WASH SOLOID.

Messrs. Burroughs, Wellcome have sent us a sample of soloids of *lotio nigra*. The usefulness of this preparation in a compact form will be sufficiently obvious to all medical men to prevent the necessity for extended comment. The soloids can be carried about in a small quantity, and the only thing required to procure an immediate supply of black wash is to dissolve one of them in the requisite amount of water. The country practitioner will find these tabloids useful in his practice, for there are many conditions in which black wash constitutes a valuable remedy, whereas it has dropped in these latter days into undeserved neglect.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

The Influence of the Central Nervous System in the Causation of Uterine Hæmorrhages.—Ehrenfest (*Amer. Jour. Obst.*, Feb., 1907).—"Intractable uterine hæmorrhage" appears with striking frequency in recent literature as an indication for hysterectomy. This is surprising. Uterine hæmorrhage is not a disease *sui generis*, but only a symptom. There are three theories by which the metrorrhagia is explained. The oldest is based upon the presence of a thickening of the tunica media of the arteries; the second, that it is due to an increase of fibrous tissue of the uterine wall at the expense of the musculature; and the third that it is due to a relative insufficiency of the elastic tissue. In this paper the author shows how functional disturbances of the uterus may be brought about by anomalous impulses transmitted to the genital organs from a normal or diseased central nervous system. After reviewing the literature, and from personal observations, he then draws the following conclusions:—(1) Impulses coming from the central nervous system may alter the normal function of the uterus in regard to both menstruation and labour. (2) The resulting effect may appear either in the form of vaso-motor anomalies (amenorrhœa, menorrhagia or metrorrhagia), or in the form of motor disturbances (sudden cessation or beginning of uterine contractions). (3) With the exception of rather vague reference to disturbances in the vaso-motor system and the uterine tonus, and No. 2 theory above, no explanation is extant of the exact mechanism by which such a nervous influence may cause the symptom of metrorrhagia or amenorrhœa. This mechanism the writer attributes to a locally increased blood pressure due to an abnormally high tonus of the uterine wall. This local increase of blood pressure will result from any tonic contraction of the uterus, which is slight enough not to cause a compression of the arteries, but strong enough to effect a cessation of the rhythmic contractions of the uterus (which help to propel the venous blood), and compression of the thinner walled veins. As a result of this passive hyperæmic condition, and the locally increased blood pressure, therefore, the endometrial capillaries must become dilated, and finally rupture causing hæmorrhage. This rupture seems also applicable to the explanation of menstruation. If, then, this theory of a locally increased blood pressure due to an abnormally high tonus of the uterine wall actually explains some uterine hæmorrhages, it should be possible to explain the sudden cessation of an existing hæmorrhage and of certain types of amenorrhœa. If the impulse from the central nervous system is a strong and firm one, the resulting uterine contraction may completely interrupt the circulation in the arteries, and suddenly stop an existing flow. In this category belong the cases of temporary suppression of menses in the fear of existence of pregnancy. F.

Acute Suppurative Peritonitis and its Operative Treatment.—Wathen (*Jour. Amer. Med. Assoc.*) formulates the following principles for the operative treatment of all perforations into the peritoneal cavity:—(1) Operate as soon as diagnosis is made, and avoid purgation and opium before and after operation. Give no food or liquid, and if there is no gastric perforation empty the stomach by lavage, and remove fæcal matter from the colon by rectal enemata. (2) Operate rapidly, and, if posible, treat the foci of infection by suturing gastro-intestinal perforations or bladder wounds, by cholecystectomy or cholecystostomy, by appendectomy, or by the removal of the uterus or its adnexa, always remembering to avoid peritoneal traumatism. (3) Expose or handle the intestines as little as possible, and do not separate adhesions or irrigate or sponge the peritoneal cavity. Establish drainage from the bottom of the pelvis through a suprapubic incision, and, if indicated, also drain the site of infection, using a large split rubber tube with or without gauze, with the patient in nearly a sitting posture. (4) Pour into the peritoneal cavity before closing the abdominal wound hot horse serum or saline solution to stimulate leucocytosis, and when the patient is in bed use saline by the rectum after the manner of Murphy. Enterotomy is hardly ever indicated; enterostomy is contra-indicated. F.

A Consideration of Neurasthenia in its Relation to Pelvic Symptoms in Women.—Weiss (*Amer. Jour. Obst.*, Feb., 1908).—Too often are patients with vague neurasthenic symptoms, such as headache or slight leucorrhœa subjected to operation in the hope that a cure will result; likewise numberless ovaries are sacrificed on account of ovarian pain where no real pathological condition exists. Not only are the neurasthenic symptoms unimproved, but new symptoms are added to the category which did not exist before the operation. Therefore, it must be remembered:—(1) That neurasthenic pelvic symptoms in women frequently exist without pathological changes in the pelvis; (2) that a careful differentiation between neurasthenia and real morbid anatomy must be made before deciding on the treatment; (3) that this form of neurasthenia is not only unimproved, but frequently aggravated by surgical treatment. F.

The Treatment of Infected Pubiotomy Wounds by Suction Hyperæmia.—Offergeld (*Monatssch. für Geb. und Gyn.*, Bd. XXVI., Hft. 6), as a result of his experiments, comes to the following conclusions:—Injuries to the vagina occurring at the time of operation must be regarded as the most dangerous complication of pubiotomy, since the immediate result is that the soft parts, and especially the ends of the bone, are infected, and the symptoms of severe septic infection arise. The different sera have been employed with very little success in these cases. On the other hand, the early induction of venous hyperæmia seems to afford us a most excellent means of not only preventing the latent infection from making itself manifest, but also of localising the disease, and of curing when even the first symptoms of osteomyelitis are present. It is reasonable to employ the suction hyperæmia as a curative agent only when no general infection *viâ* the circulation has occurred. G.

Glycosuria Resulting from Abdominal Tumours.—Evelt (*Monatssch. für Geb. und Gyn.*, Bd. XXVI., Hft. 6) records the case of a woman, æt. 41, who believed herself to be eight months pregnant. She was examined by two physicians, who told her that she was pregnant. She had not missed a period, but the abdomen had latterly become very much enlarged. A physical examination made by the author showed the following:—No colostrum in the breasts. Bimanually a very irregularly shaped tumour was to be felt, which, owing to the presence of nodules and ballotting parts, closely resembled a pregnant uterus. The urine contained a large amount of sugar. A laparotomy was performed, and bilateral ovarian tumours and a myomatous uterus were removed. The convalescence was uneventful. The author came to the conclusion that the only possible cause for the glycosuria in this case was injury to the pancreas. This injury he regards as being compression of the pancreatic duct due to pressure of the large tumours. He advises, therefore, that a diagnosis of diabetes should never be made without first carefully examining the abdomen. It would be a very unpleasant revelation for the physician to find that dietetic treatment was producing no result, which, of course, it could not do, when the diabetes is due to a similar cause as the case now recorded. G.

Forceps for the Sake of the Child.—Leisewitz (*Archiv. für Gyn.*, Bd. LXXXI., Hft. 3).—In the Dresden Klinik from 1894-1907 forceps were used 697 times among 27,238 deliveries. They were indicated 440 times on behalf of the child, 99 times on behalf of the mother, and 158 times on behalf of both. Of the 598 children to be saved, 529, = 88.46 per cent., lived. The causes of death were fracture and compression, and most frequently asphyxia, 46 having died from the last cause. The author believes that some of these children might have been saved by an earlier application of the forceps. High forceps should be no longer employed. Pubiotomy should be performed instead, even by the general practitioner. If he should not be able to perform pubiotomy, it is better to perforate. G.

MEDICAL NEWS IN BRIEF

Royal College of Surgeons of England.—The Negro Races of Africa.

On Friday last, Dr. Frank C. Shrubsall, Hunterian Professor, concluded a series of three lectures on the Negro Races of Africa. The lecturer dealt chiefly with the physical anthropology of these races from the time of the classical period, and recorded the growth of knowledge in mediæval and modern times. The Bushmen-Hottentots and the Negrillos he described as the main types of the shorter race, and the true and mixed negro people as the taller race. Dr. Shrubsall regretted that numbers of negro skulls had in the past been sent to English and other museums without any exact information as to the tribe to which they belonged, and had to be entered in the catalogues simply as "negroes from unknown localities," which has rendered them practically useless for comparative study. With the exception of the skull of the negro he further said that material for the study of the rest of the skeleton was almost entirely lacking.

Dr. Shrubsall described the history of Africa as one of replacement of one racial stock by another more richly endowed. The Bushmen were driven to the uttermost ends of the continent to take refuge in mountain fastnesses in which they were safe until the advent of the European and long range firearms against which their weak bows and arrows were powerless. At the same time the driving away of the great game and its replacement by herds of cattle converted him of necessity from a hunter of the wild animal, free to all, to a hunter of those animals which had taken their place, and as these were the property of the usurpers of his country he was termed by them a robber to be exterminated. Even those who had fled into the desert fastnesses, as yet not used as grazing grounds, had to suffer a further ill from the advent of pastoral peoples. The cattle plague which ruined many of the pastoral peoples also destroyed the majority of the great game, and so helped by starvation to exterminate the original race of South African man.

The Hottentots, driven back before the white man, make a precarious living in Namaqualand, and a few tribes, now all of mixed blood, remain along the Orange River in Griqualand. The unmixed negro is now nearly everywhere driven into the humid, unhealthy forest zone and river marshes, and has been protected therein by acquiring a certain tolerance of some parasitic diseases which take heavy toll of invading higher races. In these fastnesses the negro remains unprogressive, if not retrograde. Now, with the aid of hygienic precautions, the drainage of marshes, the opening up of clearings in the forest, the parasites which have been his protection, or perhaps rather the insects transmitting them to man, are being destroyed, and the higher races are able to live longer and longer periods in the old forbidden land. "This is doubtless all for good," continued the lecturer. "In early mediæval times a high state of culture existed among the mixed peoples in the Central Sudan, and it may be the results of a similar mixture throughout black Africa will lead to the rise of a more progressive people, who will be brought into even closer contact with European civilisation, when, by steamers and railroads, the healthy plateaux are made accessible, and become the seats of the newer Empire, in which each race may play its part."

The Queen's College, Cork.

The triennial visitation of this College was held during the month of February. The visitors were Mr. Justice Kenny, President; Sir Rowland Blennerhassett, Bart.; the President of the Royal College of Physicians; the Vice-President of the Royal College of Surgeons, and Sir John Wm. Moore, M.D. At the close of the proceedings Mr. Justice Kenny stated that the visitors, having gone through the various departments of the College, found it, as a whole, in a highly satisfactory condition. They considered that as much use as possible had been made of the finances at the disposal of the College.

Trinity College, Dublin.

The following candidates passed the Final Medical Examination, Part II., at Hilary term, 1908:—

Medicine.—Charles W. Laird (passed on high marks), Johannes C. Pretorius, Arthur H. Laird, Thomas P. Dowley, Albert V. J. Richardson, William E. Hopkins, William A. Nicholson, Robert de C. Wheeler, James F. Clarke, Herbert V. Stanley.

Alltymynnydd Sanatorium.—Royal Opening Ceremony.

It is stated by a good authority that her Royal Highness Princess Christian has consented to open on July 21st next the sanatorium which has been erected for consumptives at Alltymynnydd, Llanbyther. The West Wales Branch of the National Association for the Prevention of Tuberculosis, of which Earl Cawdor, Lord Lieutenant of Pembrokeshire, is the President, will meet next week to arrange details in connection with the reception of Her Royal Highness, who, accompanied by her daughter, Her Royal Highness Princess Victoria, unveiled the memorial stone in 1906, on which occasion she was the guest of her dear lamented friend, the late Lady Drummond, wife of Sir James Williams Drummond, Bart., Lord-Lieutenant of Carmarthenshire and Chairman of the Sanatorium Committee.

Prudential Assurance.

From the annual report of the Prudential Assurance Company, just received, we learn that the number of life policies in force at December 31st, 1907, was 843,206, assuring with bonus the enormous sum of £93,263,920, and producing a premium income of £4,477,866 per annum. The double endowment table introduced in the year 1903 has proved very successful, there being over 43,000 of these policies in force, assuring over £4,840,000; including these policies, there are 692,474 policies effected under the endowment assurance tables, where the sum assured is payable in the lifetime of the policyholder. The surplus funds in hand, including £266,387 brought forward from last year, are now £1,406,318.

School of Tropical Medicine, Australia.

The Bishop of North Queensland (Dr. Frodsham) has come over to England partly to make arrangements with the schools of tropical medicine in England to send out to Australia a trained man to start the work of the institute which it is proposed to form in Northern Queensland for the study of tropical diseases. It is intended to establish an institute, with laboratory, at Townsville, the Bishop's headquarters, and the principal city in Northern Queensland. The general management will be undertaken by the three Australian Universities having medical schools—Sydney, Melbourne, and Adelaide. The Federal Government of Australia have agreed to subsidise the work at the rate of £450 per annum, and the Government of Queensland will give £250; thus the institute will start with an assured annual income of £700, and this sum will be increased by private subscriptions. The managers of the Townsville Hospital will set aside a building for a laboratory, free of charge. Correspondence relating to the matter may be addressed to the Bishop at the Church House, Westminster.

NOTICES TO CORRESPONDENTS, &c.

☞ **CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DR. HARTLEY.—To lay too much stress upon the incident would be to indicate that our correspondent had acted unwisely in the matter.

WESTERN SUBURB.—The plea, in our opinion, is not a sound one, and should be resisted.

WHAT WE ARE COMING TO.

"Is the room disinfected?"

"Yes, mother; and I have sterilised the curtains, deodorised the furniture, septicised all the fixtures, vapourised the air, washed my lips in an antiseptic solution, and——"

"Have you septicised the mistletoe?"

"Thoroughly, mother; everything is done. Arthur is waiting now in the hydrogen room."

"Then you may go in and let him kiss you, dear."—"Lippincott's Magazine."

FOREARMED.—In view of the probability of all-night sittings at the House of Commons being necessary before very long, it is reported that the Kitchen Committee have unanimously decided to lay in a good supply of Bovril for use of members.

LAYMAN.—Our correspondent should consult his medical adviser, who, if necessary, will recommend a consultant.

PALLIDA MORS.—The statement of the patient should not be accepted without seeking for confirmation from the two medical men concerned.

MEDICAL AID.

A Newcastle correspondent writes: I am told that there are several collieries situated on the outskirts of small villages that have not a medical man living nearer than seven or eight miles, and they are without telephone connection. It is true there is the country post office for telegraphing, but even this is closed at 8 p.m., and the operator is not always available. To make matters worse, not one of these isolated collieries has a single person connected with it that knows anything about ambulance or first-aid work. There is no reason why there should not be a telephone to the nearest doctor, or that a section of the men should not be taught the principles of rendering first aid to the injured.

STUDENT.—The matter is one which we think had better be referred to the Dean of the medical school to which our correspondent belongs.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 11TH.

ROYAL SOCIETY OF MEDICINE (NEUROLOGICAL SECTION) (20, Hanover Square, W.).—5 p.m.: Clinical Meeting. Dr. W. J. Harris, Dr. P. Weber, Dr. E. Jones, Dr. P. Stewart, Dr. J. S. Collier, and others: Cases. Patients in attendance at 4.30 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Prof. R. Thompson: The Anatomy of the Long Bones relative to Certain Fractures. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. M. White: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

THURSDAY, MARCH 12TH.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNÆCOLOGICAL SECTION) (20, Hanover Square, W.).—7.45 p.m.: Dr. W. C. Swayne, Dr. G. Anderson, and Dr. Macnaughton-Jones: Specimens. Dr. A. Andrews and Dr. D. Maxwell: A Case of Difficult Labour with Remarks on the Frozen Sections of the Uterus. Dr. W. C. Swayne: Myomectomy during Pregnancy. Dr. J. H. Dauber: Large Retro-peritoneal and Subligamental Fibroid complicating Pregnancy.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture:—Dr. A. J. Whiting: Angioneurotic Œdema as a Familiar Cause of Sudden Death.

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: Ul-erythema—I., Centrifugum; II., Telangiectic; III., Ophryogenes.

HOSPITAL FOR SICK CHILDREN (Great Ormond Street).—4 p.m.: Lecture:—Mr. A. Lane: Fractures in Children.

FRIDAY, MARCH 13TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Mr. T. H. Kellock: A Case of Hermaphroditism in which the Uterus occupied the Sac of an Inguinal Hernia. Dr. F. P. Weber: A Case of Angina Pectoris with Aortitis. Dr. S. W. Carruthers: A Case of Purpura Hæmorrhagica with Fatal Result from Cerebral Hæmorrhage. Dr. J. P. Parkinson and Mr. J. S. Horsford: A Case of Cerebellar Tumour with Proptosis.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—Dr. E. W. Hope: The Results of the Methods adopted in Liverpool in the Direction of removing Insanitary Property and providing Dwellings for the Dispossessed. Followed by Discussion.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Prof. W. S. Handley: The Natural Cure of Cancer. (Hunterian Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. E. Clarke: Clinique. (Eye.)

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—3.30 p.m.: Lecture:—Mr. P. Baly: A Few Points in Preventive Dentistry and the Care of the Teeth.

MONDAY, MARCH 16TH.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Dr. F. A. Bainbridge: The Pathology of Acid Intoxication.

Appointments.

DILLON, M., L.R.C.S.Irel., L.A.H., Certifying Surgeon under the Factory and Workshop Act for the Rathmore District of the county of Kerry.

EDINGTON, D. C., M.D.Edin., Certifying Surgeon under the Factory and Workshop Act for the Penrith District of the county of Cumberland.

FARRIES, JOHN STOTHART, L.R.C.P. and S.Edin., Medical Superintendent of the Sandwell Hall Asylum for the Feeble-Minded, Handsworth, Staffs.

HARDY, ARTHUR REGINALD, L.M. and S., L.S.A.Lond., Resident Medical Officer at the Gateforth Open-air Sanatorium (near Selby) in connection with the Leeds Tuberculosis Association.

HARMAN, G. R., L.M., L.S.Dub., Certifying Surgeon under the Factory and Workshop Act for the St. German's District of the county of Cornwall.

MOORE, P. M., M.B., B.S.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Strangford District of the county of Down.

MORTIMER, JOHN, M.B.Lond., M.R.C.S., Honorary Consulting Surgeon to the Exeter Dispensary.

THOMAS, FRANK LESLIE, M.B., B.S.Lond., L.R.C.P., M.R.C.S., Medical Officer to the Barnstaple Union.

Vacancies.

North Riding Lunatic Asylum, Clifton, York.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, furnished apartments, washing, and attendance. Applications to the Medical Superintendent.

Devon County Asylum, Exminster.—Third Assistant Medical Officer. Salary, £140 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Asylum, Exminster.

Hampshire County Council.—County Medical Officer of Health. Salary, £700 net. Applications to H. Barber, Clerk of the Council, The Castle, Winchester.

Bucks County Education Committee.—Education Medical Officer. Salary, £300 per annum. Applications to C. G. Watkins, Education Offices, Aylesbury.

Saint Bartholomew's Hospital, Rochester.—House Physician. Salary, £110 per annum, with board and residence at the Hospital. Applications to Thos. Crockford, Clerk to the House Committee.

Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary, £150 per annum, all found except liquors. Applications to the Medical Superintendent.

The Royal National Orthopædic Hospital, 234, Great Portland Street, W.—House Surgeon. Salary, £250 per annum. Applications to the Secretary.

Mullingar District Lunatic Asylum.—Resident Junior Assistant Medical Officer. Salary, £100 a year, increasing to £150 per annum. Immediate application to Arthur Pinegan, Resident Medical Superintendent. (See Advt.)

Royal Victoria Eye and Ear Hospital, Dublin.—House Surgeon. Salary, £40 per annum, with full board and residence. Applications to Edward Parker, Registrar. (See Advt.)

Births.

ATKINSON.—On March 1st, at 33, Church Street, Saffron Walden, to Dr. and Mrs. H. W. Atkinson—a daughter.

HOBBS.—On March 6th, at Burke House, Beaconsfield, the wife of Geoffrey Charlstrom Hobbs, L.R.C.P., L.S.A., of a daughter.

MILLIGAN.—On March 7th, at Ardmae, Northampton, the wife of R. A. Milligan, M.D., of a daughter.

Deaths.

MACLEOD.—On March 3rd, Murdoch Donald Macleod, M.B., of Beverley, East Yorks, late Medical Superintendent Officer of the East Riding Asylum.

MAPOTHER.—On March 3rd, at 16, Welbeck Street, London, Edward Dillon Mapother, M.D., late President of Royal College of Surgeons, Ireland, aged 72.

COOPER.—On March 5th, William Bertram Cooper, M.R.C.S., L.R.C.P., of 19, Sutton Court Road, Chiswick, aged 39.

Respiratory Inflammations.

There are many reasons why Angier's Emulsion is so extensively employed in bronchitis and the various inflammatory affections of the respiratory organs incidental to the winter months. The first and most potent of these reasons is the universally attested clinical fact that the remedy quickly relieves these conditions. Equally true is it that the Emulsion exerts its curative influence in both the acute and chronic forms of bronchitis. Cough is checked, bronchial irritation allayed, and expectoration facilitated. No other remedy has such sedative demulcent and lubricating effects, while its stimulating influence on nutrition overcomes the oft-present element of systemic depression. It is no exaggeration to state that Angier's Emulsion is not only the simplest but likewise the best treatment for acute and chronic inflammatory affections of the respiratory organs.

FREE SAMPLES TO THE MEDICAL PROFESSION.

ANGIER'S EMULSION

(Petroleum with Hypophosphites).

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, LONDON, E.C.

FORMAMINT

An Excellent Antiseptic and Prophylactic in Diseases of the Throat and Mouth

EFFICIENT SUBSTITUTE FOR GARGLES

COMPOSITION: Vide Article on "Oral Sepsis" in *The Lancet*, Oct. 20th, 1906.

"A chemical combination of Formic Aldehyde and Lactose put up in the form of a compressed tablet."

"A non-toxic and trustworthy antiseptic in all ages, differing entirely from simple solutions of formic aldehyde in nature and in action being much more powerful, devoid of any irritating properties, and which on solution by the saliva sets free that disinfectant in a nascent form."

INDICATIONS: in all conditions of **SEPTIC SORE THROAT,** as **TONSILLITIS**—Simple, Septic and Follicular—**DIPHTHERIA, SCARLET FEVER, MEASLES, THRUSH,** etc.

"In ten cases of **Diphtheria** the treatment by Formamint Tablets was employed as a substitute for local treatment by disinfectant gargles, and in some of the milder cases anti-toxin was dispensed with. In all cases the improvement was rapid."—(*British Medical Journal*, January 13th, 1906, Epitome, page 8.)

"A proved antiseptic and bactericide, non-toxic in action, far more efficient than gargles or mouth washes, particularly suitable for children and entails no pain, and its portability is of considerable convenience."—*Medical Magazine*, March, 1907).

Samples & Literature on Application to

A·WULFING & Co, 83, Upper Thames St, LONDON, E.C.

"Formolyptol"

ITS

BACTERIOLOGY

The crucial test of the efficacy of an antiseptic fluid is the bacteriological one. When we state that FORMOLYPTOL is equal in germicidal potency to a 1-1000 solution of Corrosive Sublimate, without the irritant or toxic properties of the latter drug, we base our claim upon the results of careful laboratory experimentation with the different varieties of germ life. Complete and conclusive reports from prominent bacteriologists sent upon request.

ANDRUS & ANDRUS
46 Holborn Viaduct, London, E. C.
Representing
THE PALISADE M'F'G CO., New York

FORMOLYPTOL is a palatable, fragrant and slightly astringent formaldehyde preparation. It does not stain linen or clothes. Employed in Gynecology and Obstetrics, Rhino-Laryngology, Surgery and Dentistry. Also internally in the treatment of Typhoid Fever, and in the gastro-intestinal disorders of children.

If in doubt—
as to the best food to prescribe to delicate or rickety children, try an eighth or quarter of a teaspoonful of "Lemco" in half a pint of warm milk. Children who cannot digest milk often experience no difficulty with it when combined with "Lemco".

LEMCO

BROMURAL (Knoll)

(α — Monobrom — iso — valerianyl — urea).

As regards its action, it occupies a position midway between the hypnotics on one hand and the bromides and valerian preparations on the other. It is a

HARMLESS, POWERFUL NERVE SEDATIVE AND MILD HYPNOTIC,

which causes no by or after-effects, and forms the preliminary for a short, healthy, dreamless sleep, from which the patient awakes fresh and invigorated.

DOSE:— as a sedative, - - - 5 grains several times a day.
as a hypnotic - - - 10 grains before bedtime.

KNOLL & CO., 8, Harp Lane, London, E.C.

LISTERINE

The standard American antiseptic for internal and external use

Awarded Gold Medal (Highest Award) Lewis & Clark Centennial Exposition, Portland, 1905;
Awarded Gold Medal (Highest Award) Louisiana Purchase Exposition, St. Louis, 1904;
Awarded Bronze Medal (Highest Award), Exposition Universelle de 1900, Paris.

The word Listerine assures to the Medical Profession a non-poisonous antiseptic of well proven efficacy; uniform and definite in preparation, and having a wide field of usefulness.

Listerine represents the maximum of antiseptic strength in the relation that it is the least harmful to the human organism in the quantity required to produce the desired result; as such, it is generally accepted as the standard antiseptic preparation for general use, especially for those purposes where a poisonous or corrosive disinfectant can not be used with safety. It has won the confidence of medical men by reason of the standard of excellence (both as regards antiseptic strength and pharmaceutical elegance), which has been so strictly observed in its manufacture during the many years it has been at their command.

The success of Listerine is based upon merit, i.e., the best advertisement of Listerine is Listerine.

LAMBERT PHARMACAL COMPANY,

ST. LOUIS, U.S.A.

In combating serious illness, it is doubly important to be assured that the patient is supplied with genuine Listerine, as the substitutes sometimes offered by the trade are generally of undetermined antiseptic strength, and too often worthless for the purposes for which they are required

VOL. CXXXVI. WEDNESDAY, MARCH 18, 1908. No. 12.

NOTES AND COMMENTS.

Education and Co.

ONE of the latest of American fads which it is proposed to introduce over here is what is called "Co-education," and, as in all similar movements, the pioneers as a whole seem to be as wanting in humour as they are filled with enthusiasm. The secretary of the "Co-educational Public Schools Trust, Ltd.," has sent us a report of a recent meeting held under its auspices at Highgate, at which various ladies and gentlemen expressed their views on the subject. Mr. W. H. Dickinson, M.P., who presided, made the remark that people were afraid of the movement mainly because of its name, and that all the evidence he could obtain from America was in favour of co-education. This very noncommittal attitude formed a marked contrast to that assumed by the next speaker, a lady, who read a paper to prove that co-education was the one preventive of the great evil existing in public schools for boys! We have not before us the evidence on which this view is based, but simple-minded folk are apt to think that if boys and girls are brought up in big schools together, the deplorable homo-sexual practices which are carried on in some boys' schools are likely to be replaced by bi-sexual ones, with even more disastrous consequences.

Atheism v. Rheumatism.

A GENTLEMAN from Balliol College, Oxford, went one better even than this by declaring that association of the sexes was a law of the Creator; that there could be no morality if His laws were defied; and if there were no morality there could be no religion. From this syllogism it would seem to follow that this country, and most others, except a few favoured spots in America, have been without religion for ages unknown. From this dismal retrospect he absolved "the Ancients," who, he said, had given us the greatest literature, art, and philosophy, and yet educated their boys and girls together. The only "ancients" we remember who practised co-education were the Spartans, and these, alas! are not Spartan days. When, however, we recollect that in that State the girls were brought up with the boys, and accustomed to run and wrestle naked, we feel inclined to agree that in this climate the cause of morality would not be likely to suffer by adopting such practices over here, however much bronchitis and rheumatism might be thereby induced. Perhaps, however, the most unanswerable argument used was that employed by another gentleman, who said he had been converted to co-education by his daughter, who had no brother and was given the choice of her school. The young lady blushingly plumped for a mixed one, as she wanted "to find out what boys were *like*." A similar desire in our common mother, we reflect, "brought sin into the world, and all our woe."

Calls by Midwives.

WE have received another report of a much more interesting and practical character. It is issued under the direction of the Council of the London and Counties' Medical Protection Society, and embodies the result of several hundred inquiries they have made of medical men as to the working of the Midwives Act. The points as to which questions were put were: (1) the number of cases in which the practitioner had been summoned by a midwife; (2) the payment received for such cases; and (3) the nature of the difficulty for which their services were required. A large number of replies were received, and digested. The conclusions reached are, briefly: that conditions vary very much as to midwifery practice in different parts of the country; that in more than half the cases the practitioners were not paid, and that in the rest the fee averaged about 9s.; but of these fees only a few were received from the patient or midwife, the majority being paid by boards of guardians, provident dispensaries, and similar bodies; and finally that nearly all the cases were very serious and required operative interference for delayed or difficult labours.

Quem Deus.

WE beg to congratulate the London and Counties' Medical Protection Society on having put into more or less concrete form the opinions which medical men have hitherto hazarded, and we think the profession generally will desire to thank them for the labour their valuable task has involved. We heartily sympathise with those of our colleagues of whom the report says: "It is apparently the more galling to medical practitioners to be called on to assist midwives in difficult emergencies without payment, because they often regard the midwives as competing with them for midwifery practice, and doing so with the advantage of charging lower fees and of being able to advertise for patients with impunity." We hope that this report will reach those benevolent ladies and gentlemen who like to show their benevolence at the expense of the practitioners in poor neighbourhoods. The inevitable sequel of their action in training midwives and sending them out without medical control to practice on poor women is, not only that the medical man who finds it hard enough to make a living has most unfair competition to face, together with the insult of having to attend gratis at the call of his rivals when they get into difficulties, but that the poor are deprived of proper skilled attention at confinements, and many of them and their babies perish in consequence.

Unusual Counter-claim.

AN amusing case was heard before the sheriff in a county town in Scotland recently. A medical man was suing an hotel proprietor for non-payment of a bill for two years' medical attendance, amounting to £17 10s. 6d., and the defender disputed the amount and counter-claimed £3 0s. 2d. for "refreshments." There was no reasonable evidence against the amount of the bill, the chief grievance of the defender being that he had to pay 3s. every time the doctor peeped in, asked how he was, and looked at his tongue. For all the good these visits did him, he said, he might just as well have asked to see the doctor's tongue. The sheriff, however, pointed out that the doctor's books were well kept and showed all the visits, whilst as the pursuer had to come three miles to see his patient, he would not hold that 3s. a visit was an exorbitant charge. On the question of the counter-claim, the pursuer said he was charged for more liquor than he had consumed in all his days, but as it seemed that, in the words of the defender, he had sometimes had "a little bit to eat and something to wash it down with," the Sheriff eventually gave £2 against the doctor. Among the curiosities of medical appearances in the law courts we never remember "refreshments" being pleaded as a set-off against a bill for attendance.

Marylebone Mews.

AT the present moment there is some agitation going on as to the right of Lord Portman, who owns much property in the borough of Marylebone, to close certain mews on his estate and to use the ground for the purpose of building flats. As to the legal aspect of the case, we must leave that to the lawyers who advise the Council, but we most cordially endorse the medical view, put forward by Dr. Fletcher Little and others, that it would be most imprudent, from considerations of health, to close these fairly open spaces and build high blocks of flats on them. It is a palpable fact that a man must live somewhere, and that he needs a certain amount of elbow-room. It is not so well known, but none the less the fact, that the higher the density of the population, the higher the death-rate. London, especially the "inner ring," is already disgracefully over-crowded, and it needs all the air-space that can be granted if it is to maintain even the present standard of health. Every inch of ground built over in the centre of London is a nail in someone's coffin, and we can hardly believe that Lord Portman, who has done so much for the people on his London estate, can realise the toll in life and suffering from tuberculosis and other diseases that the building over of the present open spaces would involve.

LEADING ARTICLES.

THE SCIENTIFIC STUDY OF DEATHS UNDER ANÆSTHESIA.

IN the history of medicine it is often interesting to note for how long a time the scientific mind is content to accept an unfounded formula as an established proposition. After generations, or, it may be, centuries, of slumbering acquiescence, some master mind exposes the frailty of the orthodox belief, and the way is opened up for the discovery of the actual underlying laws. Something of this kind appears to have happened with regard to the subject of deaths under anæsthesia. Dr. F. J. Waldo, the well-known City of London Coroner, has written an article upon this most important matter, and deals with it in his usual trenchant and well-informed method. His article is published elsewhere in the present issue of THE MEDICAL PRESS AND CIRCULAR. If it were endeavoured to sum up the result of his investigation of the actual facts of the case, it could be tersely expressed in the manner of the famous chapter of "The Snakes in Iceland," namely, "There are no snakes in Iceland." There are, in effect, no statistics of deaths under anæsthetics worthy the name. The mortality from that cause in England and Wales, as reported by the Registrar-General, is gleaned from two sources, namely, reports of coroners' verdicts, and the death certificates of medical practitioners. These sources of information are absolutely inadequate, so far as they include anything remotely resembling any accurate survey of the total number of deaths during anæsthesia. Many coroners do not hold inquests upon cases of the kind that are reported to them, so that these particular occurrences are not brought to the notice of the Registrar-General at all. Moreover, the returns of the coroners are so unmethodical as to be practically useless for any comparative analysis. Thus, during the years 1902 to 1906 there were a total of 786 such deaths, but in no less than 204 of them there was no mention of the particular drug that was administered. It is, further, a fairly self-evident fact that the majority of cases of death under anæsthesia that come before the public occur in hospital practice. This observation brings us to the further important consideration, namely, that such fatalities in private practice for the most part escape formal notice, either by the coroner or the registrar of deaths, simply because, for obvious reasons, the private practitioner is anxious to avoid publicity, both on his own account and in order to shield the susceptibilities of his patients. Another fallacy arises from the fact that it is open to the individual judgment of the person certifying to omit any reference to deaths occurring at the commencement or end of general anæsthesia. For these and other clearly stated reasons the conclusion is inevitable that no statistics that are worth an instant's serious consideration are issued by the Registrar-General of England and Wales. Startling as this condition of affairs may be to the average easy-going citizen, it is nothing when compared with the corresponding figures of the Registrar-Generals of Ireland and of Scotland, where the attempt at a return is simply grotesque. In the face of these statements the man in the street will naturally ask, what is the worth of the familiar statistics given every week in the coroners' courts of the United Kingdom, whereby it is confidently asserted that the percentage of deaths under chloroform is such and such a figure, under ether another figure, and so on. As a matter of calm, sober judgment, it may be they are absolute assumptions, the result of mere guesswork, and that they no more represent the truth than the farrago of fraudulent nonsense of a specious quack pamphlet conveys the established axioms of modern medical science. The man in the street may well ask why, if that be the case, the medical profession have allowed him to be so long misled by statements that had all the appearance of authoritative professional utterances. Nay, more, the average medical man may well rub his eyes with surprise as he realises the Rip Van Winkle sleep into which he has allowed himself to be betrayed. If we mistake not, the article which we publish to-day will set the ball rolling in the right direction so far as the scientific study of anæsthetics is concerned. Hitherto we have had too much of collective and private investigation, and too little of scientific method in dealing with this important subject. How many medical men are ready to say with confidence that this or that anæsthetic drug is safer than any other. What are the data upon which such a conclusion can be logically founded? If Dr. Waldo be correct, no such data are in existence, and until some comprehensive scheme for obtaining trustworthy statistics can be secured, it will be impossible to make the first necessary step in any scientific investigation. In the few hospitals where anything like an accurate record is kept of cases of anæsthesia there is reason to believe that not a few administrations escape record. Dr. Waldo's recommendations are no less to the point than his conclusions. He suggests that every case in which a general anæsthetic is administered should be reported to some recognised authority, and that full details of every fatal case occurring, whether in hospital or in private practice, should be reported by the administrator, and that a subsequent public inquiry be held by the coroner. The familiar suggestion of a Royal Commission is appended, and it seems not unlikely that in the present instance it would be highly desirable not only in the interests of the community at learge, but also for the advancement of medical science. In any case, the cloud of ignorance that at present surrounds the whole tragedy of fatal anæsthesia constitutes a standing reproach to the philosophy of modern scientific medicine.

CURRENT TOPICS.

An Unhappy Slander Case.

The medical profession in Brighton has been ruffled by a particularly unhappy action for slander, which has resulted in a verdict for £100 damages. The plaintiff, Mr. Cecil Edwards, was appointed anæsthetist to the Sussex County Hospital at the end of 1906, but his election was distasteful to one of the surgeons, Mr. Arthur Buck, who later figured as the defendant in the action in question. The evidence in the case was voluminious, and an array of counsel appeared on either side. After a careful examination of the newspaper reports, it seems impossible to avoid the conclusion that the defendant was never reconciled to the fact of the plaintiff being elected to the position of anæsthetist to the hospital, a candidature which he had from the first opposed. Further, the evidence appears to have shown that the defendant had on specific occasions attributed incompetency to the plaintiff. Indeed, he had himself admitted that he would not perform an operation for £500 if plaintiff were the anæstheist. One incident that cropped up again and again was the turning blue in the face of a patient when under the influence of an anæsthetic given by plaintiff. Most medical men will probably agree that the true test of the competency of an anæsthetist is not the occurrence of a fleeting complication of that kind, but the way in which it was met, and the outcome of a series of administrations. There was not a shred of evidence forthcoming as to incompetence gauged by the standard of fatal results. The whole incident is sordid and unworthy of the goodwill that should reign amongst fellow-workers in a great and humane profession, whose work is conducted in the midst of the doubts and difficulties inherent to a science that is so far inexact and hoodwinked by the baffling barriers of unmastered natural laws. Anæsthetists are mortal no less than surgeons, and both look to their profession for a livelihood. An accusation of incompetence spells ruin to a young medical man, and the jury appear to have recognised the justice of the legal appeal in the action under notice, the necessity for which should never have arisen under conditions of ordinary professional tolerance and ethical sanity.

A Coming Franco-British Exhibition.

A circular letter has been going the round of the Press, both in London and the provinces, calling attention to the desirability of Great Britain being adequately represented in the forthcoming Franco-British Exhibition. Amongst many arts, crafts, and callings, the "art of medicine" is specifically mentioned as falling under the section of the liberal arts. According to the statement of Mr. Boverton Redwood, the chairman of the Exhibition, who writes from 56 Victoria Street, London, S.W., there are many ways in which that particular sub-section may be illustrated. "I need not dilate," he writes, "on the marvels of modern surgery and bacteriological research, but I may say that we hope to secure an instructive display of the latest appliances for obtaining aseptic conditions, and of the ingenious apparatus now employed in the culture and study of micro-organisms." The idea thus outlined is somewhat novel. There will be little difficulty in obtaining the help of the leading instrument makers, and possibly of some of the scientific laboratories. To make a public display of the marvels of modern surgery, however, would certainly not be in accordance with the traditions of medical men on this side of the Channel. In France orthodox opinion in these matters is less strict, and there is apparently no ethical objection to a well-known surgeon being reproduced *coram publico* on the cinematograph when performing a surgical operation.

The United Hospitals Conference.

The United Hospitals Conference is announced to take place on April 1st and 2nd. On Wednesday the session will be from 2 p.m. to 6 p.m., and the subjects for discussion will be motions and announcements of proposals before the last conference; payment for hospital patients, the prevention of abuse; and the mode of election of honorary staffs of hospitals. To dispose of these important subjects within the short space of four hours is a somewhat formidable essay. Our old friend the provident dispensary appears under the sub-section "Co-operation of provident dispensaries and analogous institutions with hospitals, *i.e.*, in the question of prevention of abuse." It will be interesting to learn the definition of "analogous institutions." On the morning of Thursday, April 2nd, from 10.30 a.m. to 1 p.m., will be discussed: (1) cottage hospitals; (2) the organisation of county guilds for the support of hospitals, as an alternative to the extension of the work of the "League of Mercy in the provinces"; (3) desirability of provincial hospitals adopting the system of uniform accounts recommended by the King Edward's Funds. Thursday afternoon provides a further relay of subjects, including the direct representation of the medical profession on the boards of management of hospitals; inclusion of tuberculosis as a notifiable disease, and its hospital isolation. We note a commendable absence of names, but nevertheless the majority of delegates will not be at any great loss to trace the underlying forces that determine the direction of many of the topics set forth for discussion.

London's Recognition of Miss Florence Nightingale.

By conferring upon her the freedom of the City, Londoners have formally recognised the great debt owed to Miss Florence Nightingale by the community. Owing to her advanced age the presentation was made by proxy through her nearest relative, a nephew, Mr. Shaw Nightingale. The ceremony was conducted in the Council Chamber of the Guildhall on the 16th inst., and was attended by the Lord Mayor, Aldermen, and Council in their robes. The well of the chamber was peopled with distinguished visitors, while the gallery was filled with nurses and fifty girls from the City of London Schools. The honour thus bestowed upon a great pioneer undoubtedly recognises a debt to one of the benefactors of humanity. In its way, modern nursing has done as much to alleviate the suffering of mankind as the discovery of chloroform, or the introduction of aseptic surgery. Yet all these three boons have come to us within the space of a few generations. The work that Florence Nightingale set rolling some fifty years ago in the Crimea has already achieved world-wide results. Who then would have dreamed of the marvellous immunity from camp sickness and the reduction of deaths from wounds to well nigh vanishing point that attained its scientific acme in the Japanese army during their recent campaign? All medical men will unite with one accord to do honour to the woman whose prophetic vision and genius achieved a vast revolution in the art of practical therapeutics, and out of the horrors of war created one of the most beneficent and peaceful of all callings that can minister to suffering humanity.

The Registration of Deaths from Alcoholism.

It is doubtful whether any scheme of national registration of deaths, however well conceived, would ever be wholly successful in obtaining an adequate record of causes. Such conditions as syphilis, insanity and alcoholism, for instance, would always present insurmountable obstacles in the path of conscientious medical testimony, that is to say, while the practitioner is dependent on his popularity and tact for the retention of the practice which supplies him with bread and cheese. What can be easier than to certify that death is due, let us say, to cirrhosis of the liver, and to leave unnoted the primary cause of alcohol or of syphilis? Moreover, there is the feeling in the breast of every man which is crystallised in the maxim, "*de mortuis nil nisi bonum*," and which we are given to think must reign supreme in the heart of every worthy member of the medical profession. A little while since a prominent Leeds practitioner declared that none of his brethren would be heartless enough to sign a certificate stating that a person had died from alcoholism. That, of course, is a somewhat extreme view, and we must dissent from the further reported statement that no man ever signed such a certificate except in the case of patients in public institutions. If that be the case the quality of the humanity upon which so much emphasis is laid seems to be somewhat lacking in the true ring. Every student of statistics recognises that there are serious fallacies surrounding the Registrar-General's figures regarding alcoholism.

Degrees for Pharmacists.

There will be little disagreement with the opinion of the Executive Committee of the General Medical Council as expressed to the Privy Council, that "it is highly inexpedient to institute in the faculty of medicine a pharmaceutical degree which contains no qualification in any branch of medicine." We suppose there is no use in hoping that the modern rage for degrees will find a check until, by their very multiplicity, they defeat their own object. It is perhaps a natural result of the increasing tendency of our universities to become superior technical schools that degrees should be conferred on those proficient in all sorts of crafts, and not merely on those who have cultivated letters or science. However, when graduates become as plentiful in these countries as were colonels in the United States a couple of decades ago, the title will be no distinction, and perhaps degrees will become obsolete. In the meantime, since in some professions degrees are a badge of right to practise their calling, we have some reason to protest against any confusion between one degree and another. Universities must be popularised, but the popularisation must be done with due regard to the rights of existing graduates, and a colourable imitation of the letters of the degrees in medicine would seem to be an infringement of the rights of medical graduates.

The Dearth of Assistant Medical Officers under the Metropolitan Asylums Board.

Good people who, on the score of economy or through any other motive, ignore mundane conditions, are awakened sooner or later from their blissful dreams by finding the world to be a place run on mundane lines. For many years the Metropolitan Asylums Board have treated their Assistant Medical Officers with haughty disdain, paying poor salaries, offering practically no prospects, and housing them at about the standard of an artisan. To make their lot even more enviable, when the hospitals were slack they have dismissed the officers, not actually, indeed, at the moment, relying on being able to draw a fresh supply from the open market in time of need. At last the worm has turned, and medical labour has shown itself not to be so "fluid" as the gentlemen on the Embankment supposed. Indeed, the Board are now complaining that there is such a shortage of officers that they cannot obtain a sufficient number to fill vacancies as they occur. This is excellent news. Public bodies never feel any representation so much as the cold-shoulder, and, as was the case with the Army Medical Service a few years ago, the Metropolitan Asylums Board are finding that they will have to add to the inducements of their medical service if they wish to obtain medical officers. Hitherto, we have been speaking from the point of view of medical men, but we place even above their interest that of the patients. If a proper number of candidates are not forthcoming, and if those who do come forward are not eligible, the patients' interests must suffer severely. Well qualified, diligent and skilful men are not picked up every day in any profession, and the Board, if they are anxious to do their duty by the patients, is not merely to pose as rate-saving statesmen, will lay themselves out to obtain the best quality of medical officer.

A Public Health Bill for Ireland.

We understand that the Irish Committee of the British Medical Association, a committee formed some time ago in order to meet the frequent complaints that the Association took no interest in Irish affairs, is considering at present the drafting of a Public Health Bill for Ireland. The object of the Bill is to codify the various Public Health Acts at present in force, and to provide for a more efficient sanitary executive. It is proposed that wholetime superintendent medical officers of health be appointed for counties and county boroughs, the dispensary medical officers to continue to act, if they so choose, as district medical officers of health. In addition, it is proposed to give greater powers for the erection of sanatoria, and the establishment of bacteriological laboratories. There is no doubt that these reforms are urgently needed, and having a Bill drafted may be of assistance to the Government if it should find time to legislate in regard to sanitary affairs in Ireland. If the British Medical Association had the power its numbers and wealth entitle it to be, it could command legislation, but unfortunately experience has not taught us to expect much from its exertions in regard to Irish matters. The framing of the present measure is, we cannot help suspecting, an attempt by the Irish Committee to show that it is doing something.

PERSONAL.

We understand that Mr. John Poland, F.R.C.S., late Senior Surgeon to the City Orthopædic Hospital, has resigned the post of Surgeon to the Royal National Orthopædic Hospital, to which he was recently elected.

The late Mr J. R. Turle has left £10,000 to the London School of Medicine for Women; a similar sum to the Metropolitan Convalescent Institution; and a sum of approximately equal magnitude to the New Hospital for Women (Euston Road).

Colonel J. Turton, V.D., R.A.M.C. (Vols.), is nominated for the appointment of Principal Medical Officer, Home Counties Division, of the Territorial Army.

Surgeon-Colonel G. S. Elliston, V.D., is nominated for a similar honour in connection with the East Anglian Division, and Surgeon-Colonel J. Raglan Thomas for the Wessex Division of the same force.

Surgeon-Colonel Sir Charles Cuffe, K.C.B., President of the Irish Medical Schools' and Graduates' Association, presided at the annual dinner of that body on March 17th at the Hotel Great Central.

Dr. Alfred Lingard, who has been Imperial Bacteriologist to the Indian Government for nearly twenty years, has just retired from his post.

Mrs. Bell Pettigrew is presenting the sum of £6,000 to St. Andrew's University to found a museum in memory of her husband, Professor J. Bell Pettigrew, who for 33 years was Chandos Professor of Medicine and Anatomy in the University.

Dr. John B. Hellier has been appointed Professor of Obstetrics at Leeds University.

Surgeon-Major C. R. Laurie, Army Medical Reserve, has been promoted to be Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

Dr. J. Charlton Briscoe has been elected an Assistant Physician to King's College Hospital.

Dr. Duncan Forbes, Medical Officer of Health for Cambridge, has been elected to succeed Dr. Arthur Newsholme as Medical Officer of Health for Brighton.

Mr. Andrew Carnegie has given 500,000 marks (£25,000) towards the 1,000,000 marks required for the "Robert Koch Stiftung," a fund founded to celebrate the 25th anniversary of Professor Koch's discovery of the tubercle bacillus, and to encourage research into tuberculosis prevention.

We regret to learn of the death of Dr. James Barrett, the well-known Melbourne practitioner and father of Dr. John Barrett, the great Australian cricketer.

Lieut.-Col. G. Scott, retired list, has been appointed staff officer to the P.M.O., Highland Division, Territorial Force.

Dr. R. Ashleigh Glegg, County Medical Officer of Ayrshire, has been appointed Medical Officer of Health and Chief Medical Inspector of School-children for the Parts of Lindsey.

The Home Secretary has appointed Dr. Mary Gordon, of 152, Harley Street, to be an Inspector of Prisons and an Assistant Inspector of State and Certified Inebriate Reformatories.

The Council of the British Association for the Advancement of Science has nominated Professor J. J. Thomson, F.R.S., Cavendish Professor of Experimental Physics in the University of Cambridge, to be president of the meeting of the Association to be held at Winnipeg next year.

Lord Strathcona presided on the 11th inst. at a dinner given by the Royal Institute of Public Health to members of the International Congress on Sleeping Sickness. The dinner was at the Hôtel Metropole, London, and amongst the guests were Professor Koch, Professor G. Sims Woodhead, Mr. Henry Morris, Colonel D. Bruce, Professor Santoliguido, Dr. L. W. Sambon, Colonel Lantonnois, and Professor G. H. F. Nuttall.

Mrs. Scharlieb, M.D., has been presented with her portrait, painted in oils, on behalf of 300 subscribers, in recognition of her pioneer work on behalf of women.

At a meeting of the Executive Committee of the West Wales branch of the National Society for the Prevention of Tuberculosis, held at Carmarthen, on Saturday evening, a letter was read from Earl Cawdor stating that he had received an intimation from Princess Christian that she would prefer to go to South Wales on Saturday, July 18th, and open the sanatorium for consumption at Alltymynydd, Carmarthenshire, on Monday, July 20th. The princess will be the guest of Earl Cawdor, at Stockpole Court, Pembrokeshire.

Dr. O'Connor Donelan has been appointed to succeed the late Dr. Conolly Norman as Medical Superintendent of the Richmond Asylum. Dr. Donelan has been in the service for about 15 years, and has been for some time in charge of the Portrane Branch Asylum. Dr. H. M. Cullinan, the Senior Assistant at Richmond Asylum, has been appointed Superintendent at Portrane.

A CLINICAL LECTURE

ON

SUDDEN DEATH.

By PROFESSOR ROBERT SAUNDBY, M.D., M.Sc., LL.D., F.R.C.P.,

Senior Physician to the General Hospital, and Professor of Medicine in the University, Birmingham.

The Church Litany contains a prayer for deliverance from the perils of battle, murder, and *sudden death*.

By sudden death is generally meant death which comes unexpectedly, or, if we may elaborate a little, we may say that has not been preceded by warning symptoms of its approach.

This prayer expresses a feeling which is widespread, yet, on reflection, as death is inevitable and must come to all of us, it is most merciful when it comes unawares and all is quickly over. As one gets to a time of life when necessarily the portion of existence left can only be short in comparison with that which has passed, the least reflective person may sometimes wonder in what way he shall make his exit from the stage on which he has played his little part, and would probably like to think that when the time comes he will not be long about it. I admire and envy my old friend and master, the late Professor Annandale, who only a few weeks ago, after a full day's work, having operated at the Royal Infirmary in the afternoon, was found next morning dead in his bed. In such a death, sudden though it be, there is nothing terrifying; he had done his duty up to the last, and lay down to rest from his labour. Why should we murmur if his sleep was that from which there is no awakening? He was æt. 68, so had lived nearly the allotted span of human life, and he went to his long home without knowing the weakness and infirmity of old age.

But sudden death raises certain civil and professional questions with which we, as medical practitioners, have to deal.

In our capacity of private medical advisers we are expected to foresee and forewarn against this danger, and, armed with the authority conferred on us by the law, it is our duty to give a satisfactory explanation when we can, and to aid the officers of justice in discriminating between deaths due to natural causes and those which are the consequences of crime. Hence we are called upon to familiarise ourselves by observation so far as opportunity is afforded us, and by reading and study which are open to all of us with those natural causes by which life may be unexpectedly ended.

Sudden death may occur—

1. In the course of acute disease.
2. In the course of chronic disease.
3. In apparent health.

We may leave out of account for the present all those cases where death is caused by injury or shock, for interesting as they are, they would carry us too far and exceed the limits of time at my disposal.

1.—In Acute Disease.

Death in acute disease may be tragically unexpected, and there are few circumstances under which it comes with a greater shock to relatives and to the medical attendant. Perhaps the best and commonest illustration is seen in diphtheria. I remember such a case when I was a student, and the impression then made is indelible. One of our house-physicians, a strong, healthy young man, caught diphtheria in the Infirmary; he was getting better, when he sat up in bed and died suddenly. I had a similar case at the old Hospital where the patient did not sit up and every precaution was taken. There had been no evidence of heart weakness, and I had remarked on the absence throughout of serious constitutional symptoms, although the throat condition was well marked.

Such sudden deaths occur in other acute diseases, especially in typhoid fever and pneumonia, but, happily, they are rare.

2.—In Chronic Disease.

This is a chapter which might be extended to very great length if I were to enumerate all the conditions under which it occurs. I do not here include cases in which there has been no previous illness, where the evolution of the disease has been latent, those will come in the next series; but I refer to patients who are known to be suffering from some chronic disease but death is not expected, as, for example, in chronic phthisis, where a sudden rupture of an aneurysmal dilatation of a vessel in an old pulmonary cavity may cause sudden death. I remember seeing a lady a good many years ago who was suffering from fibroid phthisis, a very chronic form of the disease, which often lasts twenty or thirty years, and I had laid stress upon this favourable aspect of the case to her husband. The next day a sudden violent hæmorrhage carried her off, and since then I have guarded myself in my prognosis against this accident.

In phthisis, too, sudden death may occur from embolism or from syncope, and either may cause death in cancer.

The liability of the subjects of heart disease to die suddenly is generally admitted, but it is chiefly where the aortic valves are incompetent that this occurs. The late Dr. Tilbury Fox, the well-known skin specialist, died in this way at a comparatively early age. He and his wife had run over to Paris for a short holiday, and while there one night he woke her from her sleep, asked her to kiss him, and died. Some pang there may have been that roused him and gave the opportunity for that brief parting, or he, too, would have been one who died in his sleep. But sudden death may occur in other forms of heart disease. I have seen a case of mitral stenosis lying quietly in bed in the ward suddenly attacked by acute œdema of the lungs, and die in a few minutes. Of the suddenness of death in angina pectoris we are all sufficiently aware.

I do not need to lay stress on the risk of rupture of an aneurysm, although it is comparatively rare; or to the possibility of death resulting from a ruptured varicose vein. But the danger of sudden death in phlebitis is not fully appreciated, or we should not have had to regret the untimely death of Sir Richard Thorne Thorne who could not be persuaded to rest while suffering from an attack of gouty phlebitis of the femoral vein.

Death may occur suddenly from the rupture of varicose, submucous œsophageal veins in cirrhosis of the liver, and, indeed, it came in this shape, without warning at Bath railway station to the great Dr. Todd, the apostle of alcohol in the treatment of acute disease, perhaps the victim of applying his own prescriptions inopportunely to himself.

Intestinal obstruction may cause sudden death in old incarcerated hernias, from the presence of adhesions set up by pelvic inflammation, from chronic appendicitis, from ulcer of the stomach, from impaction of a gall-stone; in all these cases however, there are symptoms of severe abdominal pain and vomiting, so as to suggest poisoning. The late Surgeon-General Harvey, Director-General of the Medical Department of the Army in India, had suffered for years from chronic dysentery with resulting matting together of the intestines and chronic obstruction. He came home to seek advice, but was dissuaded from an operation. He reached Bombay on his return to India safely, but in the train journey to Simla was attacked by symptoms of acute obstruction, and although the abdomen was opened it was too late to save the life of one who was an ornament to the Service and the friend of everyone who knew him.

Rupture of the spleen is another frequent cause of sudden death in malarious countries, where this organ becomes enlarged, hard and brittle, so that a blow or a fall or even a sudden effort may be sufficient to burst the capsule.

Chronic Bright's disease is accountable for many sudden deaths by apoplexy, by epileptiform attacks, followed by coma and death, by severe and fatal dyspnœa; less common are acute œdema of the larynx and acute œdema of the lungs.

It is also well known that the lives of diabetics hang by a thread. Such a patient runs to catch a train, sinks exhausted into a seat and dies from heart failure, or after the fatigue of a moderate walk or the shock of a small operation such as the extraction of a tooth, or some emotional excitement, is seized with abdominal pain, rapid pulse, and breathlessness, followed by coma and death. With all these your text-books have made you familiar.

We all know, too, that persons suffering from Graves' disease, from disease of the middle ear, from acromegaly, from bulbar paralysis, and from various forms of insanity are liable to sudden death, and that life insurance companies rightly refuse to take these risks.

3.—In Apparent Health.

But now let us pass before all my time is exhausted to the most startling and most tragic cases where death comes suddenly and unexpectedly to persons in apparent health, and let us consider some of the conditions in which that may occur.

When I was pathologist to this institution, a man who was walking rapidly along Summer Lane about 1 o'clock in the day, was seen to stagger and fall; he was picked up and brought into the hospital, which was only a few yards away, but when seen he was quite dead. I made an examination of the body and found nothing in the abdominal or thoracic organs to account for death, so I cut out the larynx with the tongue and the neighbouring soft parts and drew them down. When I had done this I saw lying over the opening of the larynx and firmly plugging it a large piece of unmasticated beef steak, which I suppose the man was eating as he hurried back to his work, and which, being tough, he had probably bolted. Such cases are rare, but it is well to know that death may be caused quite suddenly in this way, apparently from inhibition of the heart, for mere asphyxia would be far less speedy.

Some years ago a well-known English actress went to Paris for a short holiday, and took a drive in the Bois de Boulogne; while taking tea at the restaurant by the Cascade she was seized with sudden pain in the abdomen, turned pale, and died. A post-mortem examination showed rupture of a tubal pregnancy, a fact which was suppressed, as the lady was not living with her husband, and death was attributed to "internal hæmorrhage."

Brouardel relates the case of a tripe-seller, æt. 20, who fell down dead while serving a customer; both lungs were found to be riddled with tubercles, but there had been no symptoms of the disease during life.

An engineer, employed at a colliery near Rowley Regis died suddenly, and I was asked to make a post-mortem examination. He was supposed to have been in perfectly good health, and had not been absent from his work for a single day during the previous two years. I found his stomach distended with blood from a ruptured varicose œsophageal vein, and his liver in a state of advanced atrophic cirrhosis, but there was no ascites.

A man came to me in the out-patient room complaining of pain in the back; I sent him to undress, but soon after, hearing the sound of a fall, I went to him and found him dying; in a few minutes all was over. At the examination of the body we found a small aneurysm of the thoracic aorta not larger than a walnut; its posterior wall was formed by the muscles lying over the spinal column, while there was a round atheromatous ulcer in the posterior wall of the aorta about as large as a florin; the aneurysm had given way laterally, and the blood had poured into the cavity of the thorax.

A few days ago a man was walking past the General Post Office when he was seen to fall, and the policeman who ran to assist him found him dead. He was brought to the hospital. On examining the body, a rent was found in the wall of the left ventricle half an inch in length; there was atheromatous blocking of a branch of the coronary artery and fatty degeneration of the muscle supplied by this branch.

The Comte de Chambord, whom some Frenchman called Henry the Fifth, died suddenly, and at the post-mortem examination the œsophagus was found deeply ulcerated, for which no explanation was forthcoming. A less august personage, Chas. B., æt.36, was locked up at 11.30 p.m. by the police for being drunk; his cell was warm, and he had two blankets; at 2 a.m., he had some hot coffee; at 6 a.m., he complained of feeling ill, and at 7, as he was worse, he was brought to the hospital. When admitted, he was unconscious, cyanosed, and breathed stertorously; he died an hour later. The post-mortem examination showed acute sloughing of the œsophagus, which was attributed to some corrosive poison, but there was no evidence to show that he had obtained any. Was our pathologist right, or is there, as Brouardel appears to believe, some unknown cause of acute œsophageal inflammation ?

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Leon Blum, M.D., Chief of the Laboratory of the Medical Clinique at the Medical School of Strasburg. Subject : " The Value of Laboratory Methods in the Diagnosis of Typhoid Fever."*

ORIGINAL PAPERS.

DEATHS UNDER ANÆSTHETICS.

BY F. J. WALDO, M.A., M.D.Cantab., D.P.H.,

Coroner for the City of London, &c.

THE problem of deaths during anæsthesia arose soon after the introduction of that comparatively modern method of suspending consciousness for medical and surgical purposes. In the following brief examination it is proposed to deal with general anæsthesia produced by the inhalation of volatile drugs, as distinct from partial anæsthesia produced by the injection of drugs either locally or into the spinal canal, or by such mechanical agencies as freezing, or electrical currents. There is no particular need either to define general anæsthesia or to enter into the physiological action of the various drugs used for the purpose of suspending consciousness, neither is it proposed to enter into the debatable ground of the causation of death in fatal cases of anæsthesia. The main object in view is rather to ascertain, so far as may be possible, (1) the facts of the mortality due to that cause, and (2) to examine the machinery whereby statistics of the kind are officially presented to the Registrar-General of England and Wales.

(1) The mortality from deaths under anæsthesia so far as available from present statistics.

The annual reports of the Registrar-General for England and Wales for the years 1902, 3, 4, 5 and 6 give a total of anæsthetics for operations :—1902, 148 ; 1903, 146 ; 1904, 154 ; 1905, 155 ; 1906, 183 ; total, 786 ; or an annual average of 157.1 deaths. In these 786 deaths the anæsthetic used was—Ether alone, 41 ; chloroform, 479 ; nitrous oxide, 11 ; nitrous oxide and ether, 3 ; A.C.E. mixture, 16 ; chloroform and ether, 17 ; ethyl chloride, 15 ; atropine, 1 ; drug not stated, 204 ; total, 786.

It is obvious from a mere glance at these returns that they are not of much use from a statistical point of view. They merely show that a certain number of deaths takes place every year during general anæsthesia. The fact that the precise drug used has not been reported in 204 cases, or about 25 per cent., renders the figures useless so far as indicating the relative danger attached to individual drugs. Nor is the practical value of the return enhanced if we turn to the second point, namely :—

(2) The machinery whereby the statistics of the Registrar-General are obtained.

The sources of information as to deaths under anæsthesia are gathered from two sources : first, the copy of verdicts sent by coroners to the Registrars of Deaths and by them to Somerset House ; secondly, death certificates by medical practitioners. Both these sources of information are open to serious fallacies so far as the conveyance of anything like an adequate representation of the actual deaths under general anæsthesia that takes place annually in England and Wales.

(*a*) *Coroners' returns.*—It by no means follows that a coroner holds a public inquest into the cause of every death reported to him as occurring under anæsthesia. At the same time the practice of holding an inquest under such circumstances is undoubtedly more common than it was a few years ago. In the annual report of the Coroners' Society for England and Wales for 1902–3 it was specifically advised that " inquests should be held on all deaths occurring whilst under the influence of an anæsthetic irrespective of whether the friends of those specially concerned in the administration of the anæsthetic and the operation were satisfied in every way or not." As a matter of fact a certain number of coroners in England and Wales are not members of the Society. In any case it may be safely assumed that in a proportion of cases which it is impossible to estimate inquests are not held by coroners upon deaths reported to them to have occurred under anæsthesia.

(*b*) *Death certificates by medical practitioners.*—Judging from the reports of cases in the public newspapers the majority appear to come from public hospitals. Bearing upon this point is a recent statement of Mr. Troutbeck, the Westminster coroner. Of 174 deaths reported to him during the past six years as occurring under anæsthesia only three came from private as apart from hospital practice, It seems unlikely that the brunt of this particular form of fatality should fall thus disproportionately upon hospital patients. We are therefore lead to the conclusion that it is not the general custom to report deaths under anæsthesia in private practice to the coroners. There are various reasons why the friends no less than the medical men concerned in these painful circumstances should be anxious to avoid publicity. Moreover, evasion is not a difficult matter. In one case brought under my own notice as coroner, death was certified as due primarily to shock after operation of excision of eye-ball, and secondarily to heart failure. As a matter of fact the patient died five minutes after cessation of anæsthesia, from the effects of which he was stated to have partially recovered. By a simple extension of this process it is easy enough to attribute a large number of cases of death to causes other than those of the anæsthetic. Then, again, the medical man is not compelled by any statutory obligation to report cases of death under anæsthesia to the coroner, and it is natural that he should take advantage of the fact to avoid publicity of an unpleasant nature. It is open to question whether he is not bound in common law to report such a death along with all others of a violent or an unnatural kind. But the general practitioner or the operating surgeon anxious to avoid publicity are not likely to trouble their heads about legal niceties of that kind, even if aware of their existence. We may, therefore, conclude that the machinery whereby the information of the Registrar-General is collected is inadequate and defective, both as regards coroner's verdict and death certificate. Some of the foregoing points are borne out by my own experience as coroner for the City of London and the Borough of Southwark. From the non-residential character of the City and the fact that the great majority of Southwark residents are of the hospital class, the proportion of patients undergoing private operations is necessarily small. As a matter of fact, no case of fatal anæsthesia in private practice has been reported to me during an experience of 6½ years. On the other hand, the fact that my jurisdictions include two of the largest general hospitals in London offers some other returns of special interest.

During the time mentioned in one hospital which we will call A, 39 inquiries of the kind, in the other which we will call B, 21. The beds were about equal in number in the two institutions. With regard to statistics, the methods of B are much more ample than those of A. For instance, A keeps no official record of many of the administrations, such as those given by the house residents for the visiting surgeons, or by juniors acting under one of the special anæsthetists.

The name of the administrator is entered, but no account of the anæsthetic given, in the case of operations in the surgery or in the obstetrical department. In the dental and throat departments the name of operator, administrator and drug used are entered. There appears to be no definite system whereby an accurate account is kept of the number and essential details of all anæsthetics administered within the walls of the hospital.

In B, on the other hand, the system is much fuller. An endeavour is made to enter details of every anæsthetic administered within this institution. A register of deaths under anæsthetics is kept, with fairly full details, except that the name of the operator is omitted. Inquests have shown all deaths save two occurred under special anæsthetists, of whom two are resident and three visiting. That the system of administrative control is not perfect, however, is shown by the fact that one death under chloroform was not reported to me as coroner. The death in question was certified as shock after operation of excision of eye-ball. The account of the death furnished to me privately was that the patient "died five minutes after the cessation of the anæsthetic, from the effects of which he had somewhat recovered."

Clearly no sound conclusions can be drawn from any comparison of the results obtained from these two institutions, which, it may be assumed are fully abreast, if not in advance of, the majority of the hospitals of the United Kingdom in these matters. Indeed, we shall not be far wrong, in my opinion, if we assume that little is known as to the relative mortality and the actual facts of deaths during anæsthesia occurring in hospital practice generally in England and Wales, and practically nothing of the facts in private practice.

During the last 6½ years I have held inquests upon 63 deaths during anæsthesia. These all occurred in hospitals, and were distributed as follows;—

Number of Deaths.

In A (General hospital)	39
„ B do.	21
„ C (Special hospital)	2
„ D do.	1
	—
	63

It is my practice to hold a public inquiry in every case of the kind reported to me. The Coroners' Act, 1887, directs the coroner to hold an inquest in all cases in which he is of opinion there is reasonable cause to suspect that such person has died a violent or an unnatural death. There can be little doubt as to the proper legal course to be pursued by the coroner, but he is powerless without the co-operation of medical men. So long as there is no properly recognised statutory obligation upon medical men to report fatal cases of deaths occurring under anæsthesia, so long it will be impossible to obtain any adequate idea of the extent to which such fatalities occur in medical and surgical practice.

Imperfect as these particular returns are for England and Wales they are infinitely superior to those available in the case of Scotland and Ireland.

In Scotland one only source of information is the annual report of the Registrar-General. It has been the custom to classify all cases of deaths under anæsthesia under the heading of violent deaths, and the sub-heading poisons and poisonous vapours. In 1905 the body of the report specifically mentions that "among the accidental deaths from poisons there were 17 from chloroform and 1 from ethyl chloride." The official report for the year 1906 is not yet available. The method of the investigation of violent or unnatural deaths in Scotland being by private inquiry of the Procurator-Fiscal is hardly favourable to a full statement of the facts with regard to so delicate a matter as that of fatal anæsthesia. The general proportion of deaths to administrations has been to some extent, even if roughly, ascertained by the experience of other countries. Taking the average deaths for England and Wales and allowing for difference of population, and assuming, as we may fairly do, that anæsthetics are no less universally employed in Scotland, we may safely conclude that the following figures of the Registrar-General for the years 1902, 3, 4 and 5 understate the actual facts of the case:—

	1902	1903	1904	1905
Chloroform	14	17	16	17
Ethyl chloride ..	0	0		1
	—	—	—	—
	14	17	17	18

It will be noted that no mention is made of deaths under ether or anæsthetics other than chloroform and ethyl chloride.

When we turn to Ireland the returns are still more obviously misleading. In the year 1906 there is one death officially attributed to chloroform by the Registrar-General. In 1905 and 1904 three are reported under the same heading for each year. In 1903 two are reported under chloroform and one under anæsthetic.

Conclusions.

(1) That present available data as to deaths during anæsthesia are so imperfect as to be useless for the purposes of formal investigation. (It follows that the so-called statistics and published figures regarding that class of mortality are worthless and misleading.)

(2) That the Registrar-General's returns of such deaths are for the most part obtained from coroners' reports of deaths occurring in hospital practice.

(3) That only a small proportion of deaths under anæsthesia in private pratice ever come to the notice of registrars or of coroners.

(4) That imperfect as are the returns for

England and Wales, those of Scotland and Ireland are still less trustworthy.

(5) That with such imperfect data it is impossible to form any trustworthy conclusions either as to the absolute ratio of fatalities to administrations or as to the relative proportion of deaths to administrations in the case of particular anæsthetic drugs.

(6) That it is highly desirable to arrive at satisfactory conclusions regarding all deaths under anæsthesia both for the safety of the public and for the furtherance of scientific knowledge.

Recommendations.

(1) That no general or local anæsthetic shall be administered by any but a duly qualified medical man, except under most exceptional circumstances, which shall be duly reported to some recognised official authority.

(2) That full details be reported by the anæsthetist of all administrations of anæsthetics, whether in hospital or in private practice, including date, name and address of patient, of operator and of administrator, nature of operation, the drug used and other pertinent details.

(3) That a register of all administrations of anæsthetics be kept in all medical charities, poor-law infirmaries and other public institutions.

(4) That so far as possible special skilled anæsthetists be appointed to all hospitals and infirmaries, and that resident anæsthetists be provided in the larger institutions.

(5) That when the administration of an anæsthetic is entrusted to a junior qualified man he should be supervised by a skilled anæsthetist, except where he can produce a certificate of special skill and experience as an administrator, or where a skilled anæsthetist is not available.

(6) That notification be made to the coroner of all deaths occurring at any stage of general anæsthesia by the anæsthetist or by others concerned.

(7) That coroners be required to hold a public inquiry into all cases of death during anæsthesia, and that they make a detailed report to the Registrar-General, together with the verdict.

(8) That a Royal Commission with advisory powers might with advantage be appointed to inquire into the present facts of deaths under anæsthesia, together with the official machinery available for registration.

SOME OBSERVATIONS ON A CASE OF

TWIN ABORTION WITH DOUBLE PLACENTA PRÆVIA AND A REMARKABLE CONDITION OF CERVIX.

By R. J. KINKEAD, M.D.Dub.,

Professor of Obstetrics, Queen's College, Galway; Physician and Gynæcologist to the Galway Hospital; Fellow of the Royal Academy of Medicine in Ireland, &c., &c.

Some five years ago Mrs. H——, æt. 38, was admitted to the Galway Hospital suffering from metrorrhagia; she had had several children, and some miscarriages, in rapid succession.

I curetted her and swabbed out the uterus with liq. ferri perchl.; the bleeding ceased, and the next menstrual period being moderate, she was discharged; the succeeding one, being profuse, she came back to the hospital. I again curetted, with, however, only partial benefit; the uterus was soft, flaccid, and seemed to have lost all contractile power; there was an almost constant dribble, with occasional gushes of blood, and the patient was profoundly blanched.

I succeeded in stopping the bleeding by repeatedly swabbing out the uterus with iodised phenol, and occasionally plugging the cavity with gauze.

For the five years following her discharge from hospital she enjoyed capital health. She then became pregnant, and aborted at three and a half months.

She was attended by an experienced maternity nurse, who gave me the following history: That ten days previously the patient had expelled a fœtus without much pain or loss of blood, and she believed that the afterbirth had all come away; for eight days the patient had gone on well, and all discharge had ceased, but two days ago some slight hæmorrhage had recurred, and she insisted on going to the hospital.

She came in next morning. When I saw her at my visit she complained of having had much hæmorrhage during the night, and the ward nurse in charge told me there had been sharp bleeding since her admission.

The vagina was full of clots, there was a free discharge of blood from the uterus, the os externum dilated to the size of a two-shilling piece, was occupied by, and had protruding from it, placental tissue; the cervix all round and up to the vaginal insertion had a very peculiar roughened feel.

The thighs and pudendum were well washed with soap and water, the vagina was cleansed of clots, irrigated with Condy's fluid and water, and a couple of sterilised plugs were introduced to control the bleeding during the completion of preparations for operation.

Ether was administered by Dr. Rouse, house surgeon, and on removal of the plugs the vagina was again irrigated.

On exposing the cervix a, to me, novel condition was brought to view; the portio vaginalis was a dark blue colour, caused by a mass of veins passing upwards all round it, from the margin of the os externum, and vanishing from sight under the vaginal attachment; the veins, turgid with blood, were about the size of a No. 2 catheter, and so close together as to appear to be touching each other.

The os was seen to be filled with placental tissue.

On removal, with the speculum forceps, of some of the protruding mass, a bag of membranes presented. I introduced a flushing curette, and removed a male fœtus placenta and membranes; this placenta was attached posteriorly and partly laterally to the lower uterine segment; the implantation of the other placenta had evidently been partially central, for while the greater portion of it was firmly adherent to the edge of the os internum and to the lower uterine segment, the remainder of it, which hung down into the cervix and protruded from it, had evidently covered the os internum.

I failed to remove the latter placenta, that of the fœtus expelled ten days previously, by downward strokes of the curette, and only succeeded in separating it by getting the edge of the flushing curette under the portion lying loose in the cervical canal, and peeling it off by pushing upwards.

It would have been impossible to use a vulsellum or sharp hook to draw down and steady the uterus without wounding the veins covering the cervix, so I had to dispense with their aid.

The progress of the patient was entirely satisfactory, and she was discharged from hospital on the eleventh day.

The case was an uncommon one—fortunately or unfortunately, an abortion of twins is not an everyday occurrence. Referring to twin pregnancies, Jellett says, "it is only natural that while the placental area is increased in size, the proportion of cases in which that area extends into the lower segment will also be greater." Here, however, it is not a question of extension, but of implantation, and therefore I may regard the placenta prævia as unusual, unless the late Robert Barnes' suggestion be correct that placenta prævia is a frequent cause of early abortion.

That for the eight days following the expulsion of the first fœtus there was no hæmorrhage seems strange; but it appears to me to have been due to the firm attachment of its placenta, and to the pressure of the second ovum on the denuded area on its side of the os, and that the bleeding which after this time set in resulted from the partial separation of this second ovum.

The condition of the cervix, dark blue in colour, actually clothed with veins radiating upwards from the margin of the os externum, was the most interesting and uncommon feature of the case, and one which, so far as I am aware, has not been described before.

That it was due to the location of the placentæ seems to be proved by the following facts:—

There had been no symptom of varicosities of the veins of the broad ligament, nor was there anything connected with her health before, or during her pregnancy, likely to produce them. On removing the gauze plug, on the day after the operation, the veins, though still visible, were much less distended; and when examined the day before her discharge from hospital the veins had vanished and the cervix had resumed its normal appearance.

The question arises was this venous development peculiar to the case, or is a similar state, though in a lesser degree, usual in the early months of pregnancy in single placenta prævia.

In cases where pregnancy progresses to the later months, owing to the growth of the uterus and cervix, the veins would be separated from each other, and when hæmorrhage sets in a speculum is rarely if ever used, while on digital examination nothing may be observed but a peculiar feel of the os and cervix due, as Leishman remarks, "to the unusual thickening of the cervix, which is permeated with large vessels for the placental circulation."

With regard to the early months of pregnancy, he says, "there are no symptoms which enable us to recognise the condition in question, and if hæmorrhage should take place it will probably be followed by abortion, in the course of which nothing occurs likely to direct our attention to the peculiar nature of the case."

Moreover, with a single placenta the venous covering would be confined to that portion of the cervix, corresponding to site of the placental implantation, and thus if it were necessary to use a speculum to remove the ovum or placenta the veins might easily escape observation—especially if situated posteriorly or laterally.

THE NATURAL CURE OF CANCER. (a)

By Professor W. SAMPSON HANDLEY, F.R.C.S.,

Cancer Research Laboratories, Middlesex Hospital.

The Lecturer began by showing that the spread of cancer in the body was brought about mainly by a process of tendril-like growth of lines of cancer cells along the lymphatic vessels, a process to which he had given the name of permeation. He next referred to the recorded cases of the spontaneous cure of fully-developed cancer, and pointed out that, though such cases were very rare, the complete natural cure of cancer, as illustrated in what was called "atrophic scirrhus," was by no means an exceptional event. After alluding to the records of incomplete natural cure of cancer, as illustrated by the disappearance of the original growth or of its satellite nodules, the Lecturer proceeded to show that curative or regressive processes occurred normally in cancer—that there was nothing exceptional or anomalous in cases of natural cure. Lymphatic vessels along which cancer cells had grown were ultimately converted into fibrous cords in which no trace of cancer remained. Small particles of growth lodged in the arteries of the lungs suffered destruction in a similar way. Larger masses of cancer tended to degenerate from their centre to their circumference, with the ultimate result that they were replaced by a fibrous scar containing no cancer cells.

The process of repair commenced in the oldest portions of the growth, and spread centrifugally from that point, but it rarely overtook the growing edge of permeation, and was consequently as a rule ineffective to save the patient's life. It was a purely local process, and dependent upon degeneration of the cancer cells, and did not indicate the acquirement of any such blood-immunity as was found in fevers. Nevertheless, the recognition and study of Nature's mode of cure might have very valuable results.

Professor Handley asserted that it was absolutely certain that many cancer remedies had acquired a reputation simply from the observation and misinterpretation of the results of the natural curative or reparative process. Nothing had yet been discovered which could replace surgical measures, and there was some evidence to show that, even in cases where the growth could not be completely removed, Nature might be enabled through the operation to deal successfully with the remainder. The natural mode of cure in cancer involved destruction of the lymphatic cells, and consequent obstruction to the flow of lymph. Extremely painful swelling of the arm, for instance, frequently occurred in breast-cancer, and was the cause of much of the suffering connected with that disease.

As a result of his work in the cancer research laboratories of the Middlesex Hospital, he had been able to devise a simple operation for the relief of this condition. The method consisted in draining the swollen arm by a number of buried silk threads, which carried away the excess of fluid by capillary attraction. The attitude of the public to cancer research was as that of a man who sowed wheat in October and expected to reap in January. On the other hand, there was the indifference of the pure scientist, for whom absolute intellection was the absolute goal, an attitude of mind which, he said, had received rebuke from Mr. Arthur Balfour. Pending the achievement of larger results by methods yet in their infancy, he was glad to be able to produce a minor instance of the immediate fruition of cancer research.

ARTERIO-SCLEROSIS AND PHYSICOTHERAPY.

By Dr. J. A. RIVIERE,

Paris,

Editor-in-Chief of the "Annales de Physicothérapie"

[Specially Reported for this Journal.]

It is in the visceral arterioles that sclerosis of the arteries generally commences. This peculiarity explains the grave trophic disturbances which are implanted in the most important organs, the gastro-hepatic disorders, the cerebro-spinal affections, and finally, the fatal symptoms that sometimes supervene in subjects who have only just passed their fiftieth year and who are at the time in robust health. However, it is acknowledged that arterio-sclerosis generally comes on in a latent manner, causing those often indefinite visceral affections which, through their very indefiniteness, are often wrongly treated; and as their diagnosis is doubtful, the therapeutical measures are in consequence faulty. To the works of Lancereaux, already of ancient date, we first owe this pathological conception.

(a) Abstract of the Hunterian Lecture delivered at the Royal College of Surgeons, England, Friday, March 13th, 1908.

Heredity seems to play an important part in the etiology, but it is generally confounded with arthritic bradytrophy. Amongst the previous illnesses of the patient are especially found influenza, hæmorrhoids, frequent epistaxis, eczematous and herpetical eruptions, early baldness, loss of teeth. Certain acute and chronic infections, such as influenza, typhoid fever, syphilis, poisoning by tobacco, by alcohol, by lead, and by the alimentary toxins, the effect of a too generous diet, undoubtedly hasten sclerotic degeneration of the arteries. Angio-sclerosis explains the gloomy, morbid career of some rich families, the members of which are struck down by angina pectoris or by cerebral hæmorrhages long before the usual term of human life. How many persons only forty years of age, seemingly in good health, carry about their death sentence? For this reason it is as well to be able to distinguish the first symptomatic manifestations of the "presclerous" period (Huchard) before the obliterating lesions render our most skilful treatment illusory.

Therefore, curative physicotherapy should be commenced as soon as myasthenia, local poisoning, cramps and tinglings of the limbs, alternate flushing and pallor, polyuria with traces of albumin, headache with vertigo, nervous irritability, mental debility, failing sight and hearing, proclaim an arterial hypertension easily confirmed by the sphygmomanometer, the instrument so highly perfected in modern times (Gros Vaquez). Physical agents also are successfully employed against repeated attacks of bronchitic asthma, tachycardia and arhythmia, gastro-intestinal atony accompanied by gastritis, colitis, or biliary lithiasis. However, it is more often by sensory troubles, such as grimacing, slow speech, amnesia, a feeling of distress, sudden impressions, loss of the power of equilibrium, a sensation of insecurity, and that state (so evident to the patient's friends) of curious depression in regard to physical and moral activity, accompanied by tremors, awkward and stumbling gait, etc., that we are put on the track of the correct diagnosis—arterio-sclerosis. The French clinical school, and notably Professor Landouzy, has laid stress on these facts, on which we need not further dilate.

Now, it will be found that if a hypotensive physicotherapy of sufficient duration be carried out, a progressive retrocession of all these symptoms will result. According to the opinion of the highest authorities, the intelligent combating of this purely functional phase of the disease prevents the lesional and obliterating dystrophy from obtaining a firm hold. There can be no doubt of the existence of a pre-sclerous—that is to say, a premonitory—period. Who does not remember the experiments of Yosué, who reproduced in an animal the lesions of atheroma by causing, through adrenalin injections, a slightly prolonged period of arterial suppression.

In analysing the pathogeny of the initial phase, it will be seen that most of the functional troubles give notice of a notable condition of epithelial insufficiency. The chief mission of epithelium in the organism is a mission of protection against toxins, a very important property, especially in regard to the intestines, the liver, the kidneys, the thyroid. On the other hand, as soon as the arterial tissue becomes less elastic, less contractile, the blood flow is imperfectly regulated. For this reason, the arterio-sclerous patient suffers from diminution of function in all his economy, from a kind of organic poverty which has been well defined by Potain with the help of neologism "meiopragia." Lumbar pains, palpitation, muscular fatigue, despondency, abundant urine, poor in chlorides and showing intermittent traces of albumin, hard pulse, transient œdema, laboured dyspnœa, pale and yellowish colour of the face (occasionally vaso-motor disturbances producing a very great instability of the complexion), physical inaptitude for work, apathetic and irritable character, special neurasthenic affections characterised by a laborious condition of mind and of thought—all these constitute the inherent phenomena of confirmed arterio-sclerosis.

Again, we find baring of the teeth, with shrinking of the gums, heavy feelings in the legs owing to the local circulation being implicated, trifacial and intercostal neuralgia, with insomnia and tossing about in bed.

Further, presbytia or transitory amaurosis (caused by spasm of the arteria centralis retinæ), disorders of hearing, tinnitus, and a blowing sound in the ears, cataract—in short, a general diminution of organic resistance may be observed. The slightest infraction of ordinary diet brings about nocturnal or toxi-alimentary dyspnœa (Huchard). Moreover, rest in bed at night increases the toxæmic phenomena by diminishing elimination, so constituting a cause of weakness for the arterio-sclerous patient, who asserts that he gets up in the morning more tired than when he went to bed.

To a more advanced period belong the deep visceral lesions, and notably the impermeability of the kidneys with its attendant uræmic oppression, mechano-toxic dyspnœa, vertigo, nocturnal polyuria, gallop rhythm of the heart with metallic bellows murmur in the second intercostal space (Huchard), resonant diastolic bruit, showing dilatation of the aorta. The pulse is small, tense, and frequent, the cephalalgic pulsation is seen on the temples and on the forehead; amnesia and transitory aphasia, incomplete paraplegia, epileptiform fits, also are seen, whilst death takes place frequently either through sudden cardiac spasm or accompanied by cerebral symptoms. Sometimes cancer appears in the last stages of the disease. At this advanced period the most eminent medical man can only treat symptoms. Even if it be supposed that iodides or high-frequency currents can arrest and turn back the anatomical processes of sclerosis, what miracle could replace the important elements which have been suppressed and which have disappeared? It is as much as we can do to endeavour to restore to some of the already degenerating epithelial tissues their functional activity which is being lost. But we must act quickly. We must also mistrust those renitent and painful œdemata which have been qualified in too euphemistic a way as *neuro-arthritic*, and likewise those nodosities (Heberden's or others) which are supposed to be toxi-infectious arthropathies; they are characteristic symptoms of arterio-sclerosis.

Amongst drugs, the iodides, their strength moderated by alkalies, especially by benzoate of lithium, will render valuable aid. These medicines must always be preceded or accompanied by laxatives that favour their toleration by contending with the concomitant zymotic processes. When, as it frequently happens, the iodides are badly tolerated by the patient (even when combined with such bases as calcium, sodium, or strontium), I have prescribed with great success Lauder Brunton's matutinal powder: Take every morning, in a large glassful of water, 2 grammes of bicarbonate of potassium, 1.20 grammes of nitrate of potassium, and 30 centigrammes of nitrite of sodium. We thus obtain much less hypotension than that brought about by trinitrin, by nitrite of amyl, or by Trunecek's serum; this fact is easily proved.

More powerful, however, than pharmacotherapy against the functional premonitory symptoms of sclerosis is physicotherapy, which attacks the permanent symptoms of the nutritive changes, modifies deeply the most intimate exchanges, completes imperfect elimination, improves oxydation, and brings into equilibrium the dynamicity and the physiological chemiotaxis of the living human being. We all know that the action of physicotherapy, which consists in the scientific application of air, of water, of motion, of temperature, of light, and of electricity, is in absolute antagonism to bradytrophy. Now it is precisely this diathesis of slow progression that ends in an excess of incompletely elaborated material, and even in the hardening by incrustation of the arterioles, in hepato-renal insufficiency, in interstitial nephritis. By stimulating nutrition, by exercising a toni-sedative influence of the highest order on the nervous system, by favouring the peripheral circulation, and by stimulating the uniformity of cellular movement, physical agents have a beneficial power of resistance over the inevitable transformation of the functional premonitory sclerosis into sclerosis with anatomical characteristics.

Methodical gymnastics and kinesis, vibratory massage, thermo-luminous baths, carbonic acid baths, are all excellent agents against auto-intoxication. With the help of lacto-vegetarian diet, all these methods, whether combined or alternating with one another, slacken the vascular tension, diminish the plethora of the blood vessels, secure progressive hypotension and vaso-dilatation, sustain the heart in its often unequal battle, and relieve the functional insufficiency of the sympathetic.

When the arterial pressure is considerable, auto-conduction by means of the large solenoid (Darsonvalisation) sometimes lowers the tension in a few minutes. The same may be said, however, of the carbo-gaseous baths, of the hydro-electric sinusoidal applications, and of the blue light, with this difference—that these methods not only lower the hypertension, but suppress also the symptomatic albuminuria of interstitial nephritis and bring to the patients a much more complete general euphoria. Under these conditions there is certainly diminished reflex spasm in the intra-renal vessels, and a rise in the entire cardio-vascular tonus. Subaqueous massage, which it is important not to neglect, ameliorates still more the diuresis, and puts a stop to the cylindruria by regulating the pressure in the tubes and pelves of the kidneys.

In certain cases of arterio-sclerosis, generalised faradisation is of great service; the same may be said of electro-static baths and douches, whose *rôle* is evidently to forward the euphoria and to battle with the weakening of the nervous centres.

The hypertension, in my opinion, is much less alarming than the intoxication. These two conditions are not always correlative, but it must be admitted that the intoxication is a pathological syndrome, whilst the hypertension is but a symptom. Therefore the question is much less simple than certain authors seem to think when they imagine, and, moreover, quite honestly, Darsonvalisation to be the heroic and specific remedy for arterio-sclerosis. The truth of the matter is always the same. It is what Darsonval himself in 1898, and Charrin in 1899, recognised after numerous experiments: The high-frequency current possesses with regard to blood-pressure a regulating action. Applied to a person showing premonitory signs of sclerosis, the current progressively lowers tension in proportion to the acceleration of its organic exchanges, and to the operation of the lavage of the blood being carried out by stimulation of the liver and the kidneys. The action, often rapid, of high-frequency currents should, in order for it not to go beyond the object in view, always be closely followed by the specialist; it should be supported by severe dietetic measures, and aided by other medical and physical methods that favour elimination. In reality the Darsonval current throws into the circulation residual products of which the organism must be freed at any price; therefore, calomel, castor oil, diuretic drinks, heat, etc., are indispensable adjuncts.

In my opinion no physical agent acts directly on the lesional disorder, but, though indirect, the action none the less reaches the circulation, and affects also nutrition and innervation to the extent of the production of most excellent and useful results. Nevertheless, we must not lose sight of the permanent struggle against constipation, cholemia, and renal insufficiency, which are causes of grave symptoms and real dangers in arterio-sclerosis. In this manner (and only in this manner) can we anticipate apoplexy and angina pectoris. In cases of confirmed aortic dilatation, aneurysm, or coronaritis, the condensation couch is excellent to strengthen the arterial floodgates and to stimulate the nervous apparatus which controls myocardiac energy. If we persevere with this treatment ever so little, we see a cessation of the attacks, and a notable mitigation of the angina and of the dyspnœa.

For topalgia and localised neuralgia, the constant current progressively carried out as far as the patient can bear it constitutes the best treatment for choice. In characteristic gout we must endeavour to obtain uric reduction by the method of pharmaco-electric modification of the blood; ionisation with salicylate of lithium gives the most conclusive results in such cases.

Darsonvalisation, which is but a unit in physicotherapy, remains a very appreciable unit of treatment, not so much by its distinct influence on the walls of the vessels as specially (of this Apostoli had a presentiment) because it improves nutrition, and so attenuates the progressive evolution of the generalised sclerous processus.

It is but just to give a place in the treatment to actinotherapy, which is often employed with success. The violet rays have a sedative action on spasm, whilst the white and red rays improve the trophic affections. This action too is long dated, for the organism seems to have the faculty of accumulating the potential energy of the rays so as to utilise them when it is no longer directly under their influence. Thus we check the initial symptoms after having reinforced the energy of the defensive line. In relaxing a too tight vascular constriction, in suppressing arterio-spasm and vaso-constrictive nephritic meiopragia, do we not prevent formidable complications (aneurysm, sternalgia, glaucoma, visceral hæmorrhage, etc.).

Sinusoidal undulatory hydro-electric baths I think also improve to a considerable extent certain disorders of the cerebral circulation, and increase at the same time hepato-renal permeability. In this manner they constitute a method which is always efficacious in placing the endovasal pressure of the viscera in a durable condition of hypotonia. Besides, is there not invariably correlation between decompression and depuration. This is not surprising when we admit the probable *rôle* of urates, phosphates, and chlorides in the usual genesis of arterio-sclerosis, this affection being the great disease of those patients who suffer from chronic intoxication through waste of nutrition.

To sum up: I consider that we must understand in the following manner the physicotherapeutical cure of arterio-sclerosis.

1. We have to fulfil two principal indications: fortify the enfeebled myocardium and lower tension so as to diminish the work of the heart. At the same time our therapeutical duty is to push remedies as far as possible with the object of removing the intoxication of the blood and of restoring the tone of the nervous system.

2. To fortify the myocardium we advise: the high frequency or the interrupted current; thermotherapy; massotherapy applied to the thorax and to the abdomen; vibratory massage of the cardiac region. It is certain that the greatest cause of arterial hypertension is paresis of the heart. If we raise the myocardiac energy, if we diminish the constriction and frequency of the pulse we increase the expanding power of the lungs, thereby ensuring a more perfect hæmatosis. A marked sensation of relief proves this physiological amelioration, and at the same time the zone of dulness becomes more limited. Vibratory massage and monopolar effluves are also very useful against a tendency to syncope joined to tachycardia, to intermittency of the pulse, and to failure of the circulation, this last being signalised by irregularities of the beat felt at the wrist.

3. To lessen arterial tension: respiratory gymnastics or exercises as carried out with our perfected apparatus of the Zander system, carbonic acid and hydro-electric baths notably diminish peripheric resistance, and possess a remarkable vaso-dilatory action even when there is nephritis and hypertrophy of the heart. We alternate this method (20 minutes *séance* on an average) with Darsonvalisation. However, we always proceed prudently with reference to thermic degree, ampérage, duration of application, etc. In fine, when the patient cannot live in the open air, we endeavour to stimulate his pulmonary circulation, and to improve his nutritive hæmatosis by means of ozonisation. This method has a singularly good effect on renal debility, and to it we owe the cure of several cases of intermittent albuminuria.

4. If we wish to retain for physicotherapy the primordial place that it occupies in the cure of arteriosclerosis our aim must be directed more especially to the pathogenic causes of the malady, and we must not allow ourselves to be arrested by the consideration of any one symptom. It is only by combining all our resources that we can attain, without straining any of our therapeutical measures, a really brilliant synergy of defence. I will even add (by virtue of experiments that give me a right to speak) that the neuro-vascular system shows itself much more tolerant when face to face with our combined treatment than when brought in contact with univocal methods.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Cholecystostomy.—Mr. **Joseph Cunning** operated on a woman, æt. 30, who had been admitted on account of three attacks of pain in the upper part of the right side of the abdomen, accompanied by vomiting and constipation. During the last attack she was seen by Dr. Laurence, of Catford, who said she was rigid over the painful area, and that there was a distinct lump extending directly downwards from the liver in the line of the tip of the tenth costal cartilage to the level of the umbilicus. During this attack her temperature was raised for two or three days. There was no history of colic or jaundice. On admission there were no symptoms, nor could any lump be felt. Mr. Cunning remarked that the symptoms of pain, vomiting and constipation, with rigidity and fever, clearly pointed to an attack of localised peritonitis. The presence of a lump in the region of the gall suggested that this was the diseased area from which the peritoneum had been infected. It was possible, of course, that a diseased appendix situated higher than normally might be the cause. He was of opinion that gall-stones were present, and were causing attacks of pericystitis, with surrounding local peritonitis. The absence of colic or jaundice was of little importance, for he was coming more and more to the conclusion that although these last were very typical signs of gall-stones, they were met with only in the minority of cases. At the operation the abdomen was opened through the upper part of the right rectus, and the gall-bladder was exposed after a mass of adherent omentum had been removed. It was found to contain gall-stones, but, before opening it, the cystic and common duct were felt carefully with the fingers, but no stones were detected in them. After careful packing round with gauze to prevent the passage of bile into the peritoneal cavity, the gall-bladder was opened, and three large stones were removed. It was clearly seen from the shape of these stones that no more were present, for the centre one had two facets, the terminal ones had each but one facet and a rounded extremity, the whole mass being about the size and shape of a thick bent thumb. A purse-string stitch of catgut was inserted round the incision, and a drainage tube was thus fixed in the gall-bladder. The gall-bladder was further fixed to the peritoneum and posterior sheath of the rectus at the upper part of the abdominal incision, the rest of which was sutured in three layers. Mr. Cunning pointed out that it was extremely important to explore both the cystic and common ducts before opening the gall-bladder, for it was impossible to tell from the symptoms and course of the case the absence of stones in these situations. A point to be guarded against was mistaking an enlarged gland alongside the cystic duct for a stone inside the duct. The way to avoid such a mistake was to differentiate the elastic feel of a gland from the unyielding resistance of a stone; and also it can be determined by careful palpation of the cystic duct that a gland is only lying adjacent to it, whereas a stone would be, of course, within it. He thought cholecystectomy should be reserved for those cases in which the gall-bladder was much diseased, instead of its being regarded as a routine operation. Cholecystostomy is a safer operation, but recurrence of stones may take place, although cases of this are rare. With regard to the sutures used in gall-bladder cases, he preferred catgut, for there was always the possibility of some infection from the gall-bladder when it was drained, and if silk were used, sinuses would remain until the silk had been extruded.

The patient left the hospital at the end of three weeks, feeling perfectly well, but still with a tiny sinus from which a little bile was occasionally discharged.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

Meeting held Friday, March 13th, 1908.

The President, Sir **Thomas Barlow**, in the Chair.

Mr. **T. H. Kellock** read a paper on a case of

HERMAPHRODISM.

The patient, a man, æt. 25, had had a left inguinal hernia since childhood. On that side the testicle seemed normal; on the right it could not be felt. The penis was incurved, and marked hypospadias was present. At the operation for hernia two sacs were found. The upper communicated with the peritoneal cavity, and at the upper end a uterus was found, the size of a horse-chestnut. Both the broad and the round ligaments were present. A small ovary was found on the right side, the size of a haricot bean.

In reply to a query from Mr. Pearce Gould, Mr. Kellock stated that he had not been able to feel the prostate per rectum.

Dr. **Parkes Weber** read a paper on a case of

ANGINA PECTORIS COMBINED WITH AORTITIS.

The patient, a woman, æt. 42, had been healthy except for recurring attacks of angina. These gradually increased in severity, and she was brought to hospital in one which ended in death within a few hours. During life coarse râles were heard over the back and front of the upper part of the left lung. At the autopsy no lesions were found except in the ascending aorta and coronary arteries. The patient had almost certainly had syphilis, and Dr. Weber attributed the aortitis to this cause. He discussed the case in its relation to Allbutt's aortitis hypothesis of angina pectoris.

Dr. **James Mackenzie** inquired as to the effect of amyl nitrite in the case. In his experience this drug often succeeded in low tension cases and not in the high tension ones. He drew an analogy between this case and the one of intermittent claudication recently shown by Dr. Weber, which illustrated the importance of the cutting off of the blood supply from healthy muscles.

Dr. **De Havilland Hall** thought the case one of syphilitic origin. In his opinion true angina never occurred apart from aortic disease.

Sir **Dyce Duckworth** also agreed with the syphilis view of the case. He considered that true angina was due to distension of the heart, and that it occurred only in men.

Dr. **A. E. Garrod** related a case that had been published by Sir William Church. The patient died during convalescence from pneumonia, and at the autopsy he had found an acute pneumococcic endocarditis implicating the aortic valves. A fragment of vegetation had become detached, and had lodged in the mouth of one coronary artery.

In reply to a query of the President's, Dr. **Weber** said that he had not found any spirochætes in the sections. He referred to the acute nature of the coronary obstruction in Dr. Garrod's case.

Dr. S. W. **Carruthers** read a paper on a case of

CEREBRAL HÆMORRHAGE DUE TO PURPURA.

The patient, a woman, came for slight ecchymoses of the lower limbs. These recurred in spite of calcium treatment. No bleeding from the mucous membranes took place except, on one occasion, epistaxis. Shortly after the patient suddenly became comatose, and died from apoplexy in four hours. The case was afebrile throughout.

The **President** said that he had seen several such cases, but usually in severe forms of febrile purpura hæmorrhagica. As a rule the bleeding was into the arachnoid sac.

Dr. **Porter Parkinson** had recently seen a similar case. In 1906 Dr. Soltau Fenwick and he had read notes of two cases before the Royal Medico-Chirurgical Society. He had obtained good results from the administration per rectum of polyvalent antistreptococcic serum, and recommended its being employed in similar cases.

Dr. **Porter Parkinson** and Mr. J. S. **Hosford** read a paper on a case of

TUMOR CEREBRI WITH PROPTOSIS.

The patient came on account of failing sight. She had double proptosis, intense double neuro-retinitis more marked on the right side, nystagmus, absent knee-jerks, weakness of the right arm, and staggering gait. No signs of Graves' disease were present. After being four months in the hospital she died. No operation was performed. At the autopsy a firm tumour, the size of a pigeon's egg, was found attached to the under surface of the cerebellum on the right side and pressing on the restiform body. It proved to be a fibro-psammoma. There were three similar cases in the literature, and in all a tumour had been found in or attached to the cerebellum.

The **President** thought that the proptosis may have been due to the hydrocephalus, for in this condition the symptom was not very rare.

Sir **Dyce Duckworth** considered that proptosis might arise from several conditions other than Graves' disease, notably a central neurosis of the medulla.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, February 21st, 1908.

The President, Dr. A. R. **Parsons**, in the Chair.

AN EXCEPTIONAL CASE OF TUBERCULOSIS.

Dr. **James Little** said the patient, a man about 42, was admitted to hospital in November last looking very emaciated. He had only a cough, with a little pain in the right side of his chest. A few days after admission a student noticed a friction sound low down on the right side of the chest. His sputum did not give any tubercle bacilli. He complained of abdominal pain; he was always constipated, and his temperature was hectic, though not highly so, up to his death on February 8th. About a fortnight after admission it became plain that there was fluid in the right thoracic cavity, and on passing a needle it was found to be bloody. From the character of the fluid he became certain that it was due to tuberculous mischief in the thorax, but as the fluid did not cause any inconvenience he did not draw it off. Later, however, the patient got very ill, and 20 oz. of exceedingly bloody fluid were drawn off. The symptoms improved, and the patient lived for two months, ultimately dying from inability to take food, for which he had a total dislike from the date of admission. The specimens exhibited showed an immense blood clot in the right pleural sac. The lung itself did not appear to be affected by any tuberculous formation; it only appeared to have existed in the sac. The upper surface of the liver and lower surface of the diaphragm were affected by tuberculous disease, and the peritoneum was also the seat of diffuse tuberculous trouble. The case showed the certainty almost of a bloody pleural fluid depending on tuberculous pleurisy; it showed also that tuberculous peritonitis might affect the peritoneum without tuberculous disease of the inner surface of the intestine.

Dr. **Kirkpatrick** thought that the dictum about bloodstained pleural effusion being tubercular required modification; although the effusion might frequently be tubercular, certain tubercular effusions were not always hæmorrhagic. The case would suggest that in cases of primary tuberculosis of the pleura the hæmorrhagic effusion might be of considerable diagnostic value.

The **President** asked if there was any examination made of the patient's brain?

Dr. **Little**, in reply, said there were no symptoms that pointed to the brain, and no examination was made.

TWO CASES OF GANGRENE OF LUNG.

Dr. **Little** exhibited a specimen showing gangrene of the lung from a man 45 years of age, who died four days after admission to hospital. His own statement was that he was perfectly temperate, but that had to be accepted with some reservation. He had been at home for a fortnight with what he called a cold. His temperature was not at all elevated on admission. The only striking thing about him was his cough, which was incessant. On the third day the nurse noticed extreme fœtor of his breath. His expectoration was always that of pneumonia. The specimen showed excavations in the lower lobe of the right lung, differing from the ordinary cavities by having no wall of circumvallation. The whole lung was in a condition of solidification.

The **Secretary** exhibited a second specimen obtained about six years ago. The patient was a child suffering from diphtheria. The gangrenous mass was in the right lung; the destruction was quite localised, and there was a considerable amount of fibrinous pleurisy. Corresponding to the centre of the gangrenous area, and directly facing it, was a puncture, and outside, between two ribs, the puncture mark was seen surrounded by a dark blue zone. The child had apparently been inoculated with antitoxin at that point directly into the lung, and this seemed to be the cause of the gangrene. The gangrenous area was found, on examination, to contain diphtheria bacilli, amongst other organisms, and efforts to cultivate the organism from other parts of the lung failed. Pure cultures of diphtheria bacilli were also got from the spleen. It was possible, though improbable, that the diphtheria bacilli got there by means of the serum. It was more likely that the practitioner used a dirty needle, which caused a necrosis, and probably the bacilli were aspirated, and grew in the necrosed part, while they would not grow in the more healthy parts of the lung.

Dr. **Day** said the case was that of a boy of five, who came into hospital in January, 1902. He had ordinary diphtheria, and was injected with 4,000 units before admission. About two days after admission he got symptoms of pneumonia, which, however, disappeared. He then developed great fœtor of the breath, and the case was diagnosed as gangrene.

Dr. **Kirkpatrick** asked Dr. Little if he had formed any opinion as to the cause of the condition in his case. That primary gangrene of the lungs should start in a healthy man seemed a very unusual occurrence. They saw it occasionally following aspiration in pneumonia, and especially in patients who were anæsthetised.

Dr. **Little**, in reply, said they found no evident cause of the gangrene. The only lesion the patient had was diseased kidneys, and during life he had albuminous urine. Their knowledge of the condition was not at all precise.

DIVERTICULA OF THE URINARY BLADDER.

Mr. L. G. **Gunn** exhibited five specimens of above. The specimens were, he said, of acquired diverticula. Congenital diverticula might occur in a very young bladder, but he had never seen a congenital case. Acquired diverticula commonly occurred in the aged, and were due either to (*a*) increased pressure; (*b*) chronic inflammation of the bladder wall; or (*c*) diminished blood supply occurring from arterial sclerosis. As to how diverticula occurred, they went through three stages; some obstruction took place, and the bladder hypertrophied in order to drive the urine out. With the increase in the thickness of the muscle covering the bladder wall, fasciculation in the inner wall occurs, followed by a certain amount of atrophy of the muscle. The bladder then commenced to dilate and to thin out in places. Then a bulging occurred between the inner muscular fibres, and the mucous membrane protrudes, and so a diverticulum is formed. He did not know if it was possible to diagnose the condition in any other way than by cystoscopic examination. It had been suggested that it might be suspected if, when on washing out a bladder, a sudden gush of foul urine and some matter followed the clear return flow along the catheter. Were diverticula of much importance clinically? He did not think they were. They might conceal a stone, they certainly prevented efficient washing out, and they were a source of danger of rupture in flushing a bladder. It had, however, been a matter for wonder to him that they did not rupture spontaneously. In three cases of bladder rupture which he had seen, there were no diverticula.

Dr. **Stokes** said he had seen a case where a man had a hernia which emptied when he micturated, and swelled up when he did not. The case was easily diagnosed as diverticulum. The only hope of curing such a condition was to excise it.

Dr. **Gunn**, in reply, agreed to Dr. Stokes' opinion as to the cure of diverticula, but the operation was an exceedingly dangerous one, as they were dealing with a bladder which probably had a poor blood supply and a septic inside.

THE SOCIETY FOR THE STUDY OF DISEASES IN CHILDREN.

Meeting held Friday, February 21st, 1908.

Dr. Edmund Cautley in the Chair.

A paper was read by Mr. H. S. Clogg on a case of

ACUTE INTESTINAL OBSTRUCTION

produced by a band, the latter being in part a diverticulum bearing an accessory pancreas; resection of a foot of gangrenous intestine; recovery. A boy, æt. 12, immediately following a blow on the abdomen, developed signs of acute intestinal obstruction. When seen about 44 hours after the onset of symptoms, he was very ill, and evidently suffering from some form of intestinal obstruction. The presence of a rounded and resonant swelling in the right iliac and hypogastric regions suggested a volvulus as the cause. Operation was performed about 46 hours after the commencement of the illness. About one foot of small intestine was snared under a band of this loop, and the gut was also twisted on its mesenteric axis. The intestine appeared gangrenous, and was excised. The ends were anastomosed by Murphy's button. The band and diverticulum were removed. The boy's condition was precarious for several days, but he ultimately made an excellent recovery. The interest of the case lay in the nature of the band. It was composed of an intestinal diverticulum some ¾ in. in length, with more or less perfectly formed intestinal walls. Attached to the distal extremity was a flattened glandular body ¾ in. in diameter, which showed the structure of the pancreas on microscopical examination. Leading from the extremity of the diverticulum at its junction with the accessory pancreas was a definite rounded cord consisting of fatty and fibrous elements. The diverticulum was regarded as a true congenital one.

Mr. **Hugh Lett** agreed that the specimen was a diverticulum, and thought that the strongest argument in favour of this was the thick round cord which was connected with the diverticulum. The prognosis in cases of acute intestinal obstruction due to Meckel's diverticulum was very grave, for, of 21 cases mentioned, no fewer than 16 died; that was a mortality of 76.2 per cent., compared with a mortality of 53 per cent. for all cases of acute intestinal obstruction. One reason which had been given for this high mortality was the frequency with which the diverticulum itself became gangrenous in consequence of its being rotated on its own axis, and so strangulated by the coil of intestine which it obstructed.

Two Specimens of Congenital Morbus Cordis were shown by Dr. **George Carpenter**. The first was from a female, aged 10 weeks. When admitted to hospital she was anæmic, ill-nourished, and ill-developed. Her tongue was large, and protruded from her mouth, and she did not close the lips over it. The cartilages of the last four ribs were absent. She was not cyanosed. The area of cardiac dulness was increased to the right, and there was a loud systolic bruit best heard over the pulmonary orifice; it was audible over the back and front of the chest, louder on the left side than on the right. Ten days after admission she was convulsed, and some hours afterwards died, collapsed. The aorta rose from both ventricles, four-fifths of its lumen being over the left. The pulmonary artery was small, and but half the size of the aorta; it had two semi-lunar valves. The ductus arteriosus was patent and of the size of a small probe. The foramen ovale admitted an ordinary lead pencil. The auricles were of equal size and thickness. The heart was inclined to be bun-shaped, and the left ventricle was twice the thickness of the right. The tongue was examined microscopically, but nothing abnormal was seen.

The second specimen was from a female, aged nine months. When admitted to hospital she was very pale and thin, and suffering from pneumonia. She died on the following day. There was a loud systolic murmur best heard over the third left interspace, audible back and front, better on the left side than on the right, and also to be heard in the great vessels of the neck. The pulmonary artery was larger than the aorta. It divided right and left into branches for the lungs, and ended in a third vessel which practically continued the thoracic aorta. The aorta having given off the usual vessels, was contracted at its junction with the ductus arteriosus, being at this point a trifle larger than the innominate artery. Beyond the union the artery was smaller than the branches to the lungs being 3-16 in. in diameter. The right and left auricles practically formed one chamber, though its right side was twice as thick as, and larger than the left The auricular septum was represented by a translucent membranous partition of semi-lunar outline hanging from the roof of the auricle and attached back and front. It measured a trifle more than a ½ in. in depth, and about ⅜ in. from before backwards. Posteriorly it was somewhat fenestrated. The heart was inclined to be rounded on the right side. The left ventricle, though apparently more muscular than the right, did not bear the usual relationship in regard to thickness. The cavity of the left ventricle was smaller than that of the right. Dr. Carpenter said that although the malformations were so dissimilar, the physical signs were practically identical. Further, the bruits that were heard were the same as those audible in stenosis and atresia of the pulmonary artery and the perforate septum ventriculorum. They well illustrated how deceptive the auscultatory phenomena are as a means of determining the nature of cardiac malformations.

Dr. **Poynton** said that cases of patent ductus arteriosus were described as having a long bruit heard to the left of the sternum, which occupied the whole systole and diastole as a sort of continuous humming murmur. But it had also been recorded by the late Sir William Broadbent and others that the same continuous murmur was associated with a patent septum ventriculorum. He asked whether Dr. Carpenter thought that the murmur in a patent ductus arteriosus was exactly like the murmur in his first case, or whether it struck him that it occupied the whole systole and diastole. He would also like to hear if any member had an autopsy on a case where there was a continuous humming murmur over the pulmonary region. Cases of the kind which he had seen had done remarkably well. He had three which were still alive without any cyanosis, though with some shortness of breath.

Dr. **William Ewart** said that Dr. Poynton did not refer to the possibility that some cases might be intrathoracic venous murmurs.

Dr. **Charles W. Chapman** said that such cases met with in children did not seem to die, yet the murmur did not seem to be met with at a later age. He did not know what became of them. Some of the patients in whom there was a continuous murmur went about quite well, and there were no symptoms.

Dr. **Carpenter**, in reply, said that the murmur in the second case was exactly similar to that which was audible in stenosis of the pulmonary artery. He thought an identical murmur was produced in stenosis of the pulmonary artery with a patent septum ventriculorum and without a patent septum ventriculorum.

In the second case there were two factors in the foramen ovale and a patent ductus arteriosus where the ductus arteriosus and the aorta joined, there was stenosis, and a murmur might have been produced at that point. He did not think the murmur was caused at the foramen ovale, as it was systolic in point of time.

Specimens from a case of frontal *Meningocele and Spinal Myelo-Meningocele* were shown by the **Chairman**:—

(*a*) The skull cap showing—(1) a circular orifice in left frontal bone through which a meningocele projected during life; (2) the remains of a cephalhæmatoma in the left posterior parietal region, with some subdural hæmorrhage under both parietals; (3) isolated patches of cranio-tabes.

(*b*) A myelo-cystocele from the lumbo-sacral region showing that the arches of five vertebræ were defective, and that the spinal cord could be traced from the canal to the lower end of the tumour. The specimens were from a male child, aged 18 days. Labour was instrumental. He was the seventh child, and the mother had had no miscarriages.

A case of *Cerebral Ataxia and Imbecility* was also shown by the **Chairman**. She was a girl, æt. 2, and only weighed 14 lbs. 14 ozs. She had been deserted by her mother. She was unable to stand, walk, or talk; she could sit up, use her hands, and feed herself with bread or biscuit, but would not use a spoon. There was coarse tremor of the hands, and the knee-jerks were exaggerated. The head was 17½ in. in circumference, she had 12 teeth, and the fontanelle was still unclosed. The mother had had two miscarriages, two still-born children, and had one other child, æt. 3.

Dr. H. T. **Thompson** thought it a case of imperfect development of the brain in which the convolutions were small.

The **Chairman**, in reply, thought that the condition was due to either meningeal hæmorrhage or encephalitis, or else that it was one of backward development, the so-called agenesis corticalis. The main incidence of the disease was on the prefrontal convolutions, the motor area being very little affected, but that it was affected was shown by the ataxia in the hands, and perhaps also by the delay in learning to walk. He thought the child would always be more or less backward, though the amount of imbecility was difficult to estimate at present. She would be able to walk as there was no muscular defect, and as she was now bright, her mental condition might become clear.

(1) A case of *Angioma of the Right Auricle and Meatus* was shown by Mr. P. **Macleod Yearsley**.

(2) A specimen from a fatal case of *Labyrinthine Suppuration*, and

(3) A case of *Suppuration of the Right Labyrinth* which recovered under operation.

A case of *Bronchiectasis and Pulmonary Tuberculosis* in a boy, æt. 16, was shown by Dr. T. R. **Whipham**. The former condition having apparently supervened on an attack of pneumonia when the patient was 14 months old. X-rays showed a marked opacity of the left side of the chest and scattered patches on the right. There was no polycythæmia.

Dr. H. T. **Thompson** did not regard it as an ordinary straightforward case of bronchiectasis because of the greater incidence of the disease on one side. The history of the case, and the fact that the heart was displaced towards one side seemed to suggest as a primary lesion pneumonia of the left side which had been followed by some dilatation of the bronchi. There must have been a secondary infection with tubercle as the bacilli of that disease had been found. He thought that the lung was fibroid.

Dr. **Whipham** said that the prognosis was a bad one. The boy had been fairly well. He last year showed a child before the Society with signs on one side of the chest and slight signs also on the other. Post-mortem there was multiple bronchiectasis in one lung, and the other was emphysematous.

A case of *Incomplete Congenital Ophthalmoplegia Externa* was shown by Mr. **Sydney Stephenson**. The boy was 8 years old, well nourished, with adenoid facies. No syphilitic stigmata could be found in the face or teeth. Pupils responded to light and accommodation. There were no corneal opacities and no Hirschberg's vessels; there was incomplete but bilateral ptosis. The movements of both eyes were deficient in all directions. The greatest range was downwards, while the excursions inwards, outwards and upwards were less than 2 mm. in range. There was no evidence of paralysis of the seventh cranial nerve. The knee-jerks were absent, though the ankle-jerks were present.

The **Chairman** asked whether Mr. Stephenson had seen cases occurring after birth affecting either the external muscles only, or only the internal vessels, and, if so, what explanation was offered.

Mr. **Stephenson** said, in reply, that he could not answer the question except by saying that after diphtheria the internal musculature of the eye might suffer, or sometimes, as in cases published by Dr. Parkinson, the external musculature.

(2) A case of *Persistent Capsulo-Pupillary Membrani and Hyaloid Artery with Atypical Development of the Vitreous* was also shown by Mr. **Sydney Stephenson**.

A girl with *Inherited Syphilis* was shown by Dr. **Porter Parkinson**. The case showed the following features: infantilism with want of development of breasts and uterus with absent catamenia, periostitis chiefly of tibiæ and ulnæ, synovitis of knee and elbow-joints, nephritis, and a marked *café-au-lait* complexion.

Dr. **Poynton** said he had attempted in one of his cases to obtain the spirochæte from the fluid drawn off from the joint, but without success. He had recently had a case of Charcot joint in an adult in which several people were able to demonstrate micrococci in the fluid.

Dr. **Carpenter** asked whether Dr. Parkinson could say what the condition of the ovaries was. Infantilism occurred in diseases of the testicle and in testicles which were immature, but he did not think a case had been recorded in which disease of the ovaries had brought about infantilism.

Mr. **Stephenson** asked whether the fundus oculi had been examined, and, if so, what was found? The remains of interstitial keratitis never wholly disappeared, and probably one could always find in people who had suffered from interstitial keratitis at any time of their life very fine vessels in the depths of the corneæ.

Dr. **Parkes Weber** alluded to the enlargement and curving of the tibiæ, and thought that cases such as these led some authorities to consider the osteitis deformans of Paget a syphilitic disease.

Dr. **Porter Parkinson**, in reply, said examination of the fundus of the eyes revealed nothing abnormal, and said he would have the fluid in the knee examined for micro-organisms. The amount of albumin in the urine had not decreased while he was using mercury.

Dr. **Carpenter** said he had given mercury in cases of syphilitic nephritis without curing them, but they were none the worse for the treatment.

A case of *Enlargement of the Upper Jaw* in a boy, æt. 9 years and 10 months, was shown by Mr. **Philip Turner**. He had no pain, but the swelling which had been noticed three months previously was increasing in size; it extended upwards to the margin of the orbit, bulging forwards so as to obliterate the canine and incisive fossæ. The alveolar process was larger than on the right side, and the palate was slightly depressed. There was no exophthalmos, and no obstruction to the passage of air through the left nasal fossæ. Egg-shell crackling could be obtained by pressure on the anterior surface. Six teeth were present on each side of the middle line in the upper jaw. On the right side the first permanent molar was present with two permanent incisors, the two temporary molars and temporary canine. On the left side there were two temporary incisors, the temporary canine, two temporary molars, and the first permanent molar. The second dentition was thus considerably delayed. The skiagram showed the two retained permanent incisors on the left side, the lateral incisors had a well-formed root, but that of the central incisor was short and abrupt, while from it a definite shadow was continued in an upright direction. The existence of the swelling, with egg-shell crackling, suggested the presence of either a growth, probably a sarcoma, or a follicular odontome, frequently known as a dentigerous cyst. The short history suggested the former, but the non-eruption of the incisor teeth, together with the appearance of the central incisors in the skiagram, pointed to the latter as the correct diagnosis.

Mr. **Russell Howard** thought another possibility was myxomatous tumour of the upper jaw.

Mr. **Clogg** said that, in addition to the outer wall of the alveolus being protruded, there was bulging of the inner wall also. That seemed to him to favour its being a neoplasm of a sarcomatous nature, especially as it had grown somewhat rapidly.

Mr. **Lockhart Mummery** suggested that transillumination should be tried before going further.

Mr. **Turner**, in reply, thought there must be something more than retained teeth, as there was definite swelling, and the bone could be felt to give way.

A case of *Multiple Arthritis* in a girl, æt. 10, was also shown by Mr. **Turner**. Six months ago there was painless swelling of the right knee-joint; this was followed by a similar trouble in the left knee-joint, both wrist-joints and the first inter-phalangeal joints of both hands. There had been no constitutional disturbance and no pain in the affected joints. Both knee-joints were markedly distended, and the ends of the bones appeared to be enlarged. Thickened synovial fringes could be rolled under the fingers, and grating could be felt on flexion of the knees. The spleen could not be felt, and there was no general enlargement of the lymphatic glands. No history of any previous disease could be obtained, and there were no signs of congenital syphilis. No local source of septic infection was present.

Mr. **Turner** considered the diagnosis lay between congenital syphilis and osteo-arthritis. He favoured the latter diagnosis.

Dr. **Whipham** thought the case was one of osteo-arthritis in children; they occurred rapidly, painlessly, and without temperature.

A case of *Hæmophilia with Adhesions in the Knee-Joint* was shown by Dr. **Kenneth Kellie**. When three years of age, the boy cut his finger, and the resultant bleeding was difficult to stop. Since then he had suffered from bruises which appeared without any cause, and the right elbow and knee-joint frequently swelled and became painful. The right knee-joint was in a condition of semi-flexion. He brought the case before the Society in order to hear any opinions as to the treatment of the knee.

Mr. **L. Mummery** advised that an anæsthetic should be given, and an attempt made to break down the adhesions, though there was the risk by so doing of re-starting hæmorrhage into the joint.

Dr. **Poynton** thought that if the adhesions were broken down now, there would be no danger of bleeding into the joint, and that the limb could be got into position. Calcium chloride had been in his hands very disappointing.

Dr. **Porter Parkinson** agreed with Dr. Poynton as to calcium chloride. He had used fibrolysin in the case of a boy with a large scar in the neck made by a burn with satisfactory results.

Army Medical Service.

The following have been officially gazetted:—Surgeon-General J. D. Edge, C.B., M.D., is placed on retired pay; Colonel G. D. Bourke, C.B., to be Surgeon-General, vice J. D. Edge C.B., M.D.; Lieut.-Colonel H. W. Murray, M.B., from the Royal Army Medical Corps, to be Colonel, vice G. D. Bourke, C.B.

Royal Army Medical Corps.—Lieut.-Colonel S. F. Lougheed, M.D., C.M.G., retires on retired pay.

Paris, March 15th, 1908.

The Prognosis of Cancer.

Prof. **Reclus** chose, a few days ago, for his clinical lecture the subject of cancer as regards its prognosis, which was published in the *Journal des Practiciens.*

For the last fifteen or twenty years, he said, new treatments have seen the light almost every day, amongst which may be mentioned: Radium-therapy, radiotherapy, currents of high frequency, salts of soda, potash, quinine, and numerous analogous preparations, as well as an infinite number of serums. Strange to say, everyone of these methods appeared at the beginning at least to produce, if not always a cure, at least considerable improvement.

Surgeons of all countries rushed to these vaunted remedies, but less than a decade sufficed to undeceive the most sanguine.

At first it seems difficult to explain how men of science could have allowed themselves to be enticed by these deceptive discoveries, and to publish some ephemeral successes. But it must not be forgotten that those affected with cancer are patients treated without much conviction, and frequently abandoned to morphia. Suddenly a saviour appears and communicates his confidence; hope revives with the desire to live, sleep returns, appetite and strength increases, and both patient and surgeon are carried away by enthusiasm, and end by proclaiming as incontestible, imaginary cures.

But the true source of our errors lies in our ignorance of the progress and development of cancer. As soon as the histological examination, with or without clinical aid, permits us to diagnose a malignant tumour, the patient is condemned without any possible appeal. We conclude that the same structure will have a similar end, and since the anatomical elements are the same, and grouped in an identical tissue in each of the tumours, the patient suffering from one kind will have the same lot as one suffering from the other. We forget that there exists besides a series of unknown conditions which constitute that which, in our ignorance, we call "malignity," certain neoplasms progress very rapidly, and kill in a few months, while others require years.

Text-books on general pathology teach us that cancer terminates fatally always, and that in a very short time. The first point is but only too true, and one could count on the fingers the authentic cases of cancer cured spontaneously.

But if the termination is always fatal, at least it is not always rapidly so. There are certain cancers which develop very slowly.

Certain cancroids of the skin, for instance, frequently, especially of the jaw, forehead, nose, and those that can also be met on the limbs over old ulcers or cicatrices, persist years and years without affecting the general condition of the patient. The same might be said of certain epitheliomas of the mucous membrane of leucoplasic surface.

A third variety of cancer of slow development is constituted by a curious variety scirrhus.

Prof. Reclus treated an old lady for ten years whose breasts were covered with, so to speak, a coat of mail of rough and hard skin, and who was finally carried off by some pulmonary complication.

Certain visceral causes are not incompatible with prolonged life. Neoplasm of the bladder can remain dormant for years, while cancer of the kidney is not always rapidly fatal. M. Guyon cites a case of a magistrate who would not accept an operation in spite of frequent hematuria, and who lived for nineteen years afterwards.

We have only spoken up to now of cancers left to themselves, but I have no intention of forgetting the prognosis of cancers submitted to operation. If all surgeons are agreed in affirming that the knife is still the best treatment of malignant tumours, many sustain, and, no doubt, with reason, that medical treatment following the operation is capable of preventing relapse, and some propose the employment of certain serums, whilst others have recourse to radio-therapy, either over the open wound or under the skin covering the seat of operation, to obtain immediate cicatrisation.

Here, again, we are confronted with some of the complex nature of cancers; the same paradoxical developments, sometimes rapid, other times slow, and contrary to the usual clinical rules.

What do we know, for instance, of epithelioma of the tongue? Outside surface epithelioma of leucoplasic mucous membrane we declare this cancer to be the worst of all cancers, and Denonvilliers used to say that every ulcerated cancer of the tongue killed within a year. Yet there are cases of cancer of the tongue which do not return after extirpation. Twenty-two years ago M. Reclus removed a cancer from the tongue of a jeweller, and he is still living!

Cancers of the breast are so frequent, and operations so numerous, that statistics bear on hundreds of cases of non-recurrent cancer.

Cancer of the uterus was considered 20 years ago as almost rapidly fatal, and the prolongation of life after extirpation was insignificant. But since then we have altered our sombre prognosis, and numerous gynæcologists publish encouraging statistics, amounting in some cases to 30 per cent.

Cancer of the rectum remains always grave, prolongation of life after operation being the least marked.

If you have followed my ideas, concluded Prof. Reclus, you will have found that I tried to show you that development of cancer before operation is not always progressive, that it may remain dormant for several years, and that after operation a definite cure is obtained in about one-third of the cases.

But as I have already said, we have yet to learn the reasons why two identical structures can, in the same organ, at the same age, in persons of the same sex, have in one case a slow development, or can be cured by operation, and in another assume rapid strides and carry off the patient in spite of the earliest and most complete extirpation. Consequently, in each case our prognosis must be reserved. The fact is we know, up to the present, nothing of the origin and nature of cancer.

Gold in Therapeutics.

Prof. Grassel employs chloride of gold and sodium in chronic rheumatism.

Chloride of gold and sodium, 2 gr.
Water, 10 oz.

A tablespoonful at each meal (2) during 20 days a month.

Dr. Bué injects a solution of 1—90 into tuberculous ganglions, while Prof. Lemoine prescribes bromide of gold in epilepsy.

Bromide of gold, 2 gr.
Water, 8 oz.

One or two teaspoonsful at evening.

Prof. Robin prescribes the same bromide in the treatment of cancer of the stomach and in that of cancer in general.

Bromide of gold, 1 gr.
Water, 10 oz.

A tablespoonful at each meal (2).

GERMANY.

Berlin, March 15th, 1908.

At the Medical Society, Hr. W. Körte spoke on

Resection of the Lung for Bronchiectic Cavities.

He described the differences between bronchiectic cavities and those produced by abscesses and gangrene. In the latter case there was generally one large cavity that could be easily laid open and drained; in bronchiectasis a large tract of lung was the seat of a system of cavities, the extent of which it was difficult to make out thoroughly. Neither was it always easy to differentiate between them and abscess or gangrene cavities. He had performed pneumonotomy for abscess or gangrene 28 times. Of these, 20 recovered; on the other hand, of those who had been operated on for bronchiectasis, only 4 recovered. In the 11 that died, the autopsy showed that recovery could not have been brought about by pneumonotomy.

If anyone would operate in these cases, it was necessary to make a large window in the thorax, for which at least two ribs must be resected. According to whether the pleura was adherent or not, it must be first sutured and the lung then opened. A cylindrical cavity was then reached, into which, as a rule, neighbouring cavities opened on all sides. These cavities were opened gradually one after another, usually at several sittings, in which the separating tissues were cut through and the bleeding vessels ligatured or stitched round. This operation could be performed under either local or general anæsthesia. The individual cavities were tamponaded with iodoform gauze, soaked in Peruvian balsam. If recovery was not brought about in this way, then contraction could be advanced by extensive resection and thoracic plastique. If this was not successful, nothing remained but removal of the whole of the affected part of the lung.

In connection with the remarks he had been making, he showed a boy, æt. 8, who was admitted into hospital in August, 1906, on whom during the course of the year he had performed all the operations described, with the result finally that he was now quite sound. He came with purulent expectoration and an exudation at first serous, but which soon became purulent.

The empyæma was first emptied by resection of ribs, and in a few weeks the boy was discharged improved. He soon returned, however, with offensive sputum. Pneumonotomy was performed in December, and gradually a whole system of cavities was opened; but even after this there was no improvement. In March, 1907, extensive thoraco-plastique was performed, after which the suppuration continued unchanged. In April the whole right lower lobe was divided and adjusted, after which the expectoration ceased, but the suppuration from the lung continued. On May 26th the whole of the right lower lobe was again opened up as far as the hilus, and a portion of the middle lobe resected. After cleansing the wound, the large flaps of the soft parts formed in the thoraco-plastique, which had shrunk in the meantime, were straightened out, and sutured so that the stump of the afferent bronchus was covered. The wound healed without the formation of a bronchial fistula, the boy recovered, and he was now quite well.

The chief dangers of operations on the lungs were hæmorrhage and sudden collapse at the moment of incising the lung. Both the speaker and others had witnessed sudden death at this point, probably through reflex in the vagus, against which we were powerless. The danger of pneumothorax was not so great here if the lung was grasped quickly and drawn out. He had not made use of the Sauerbruch chamber; it could be dispensed with, and from the moment when the lung was opened it was useless.

Hr. Krause reported on a case that had remained well since 1899. It was that of a man, æt. 34, in whom a pulmonary fistula remained in consequence of an operation performed elsewhere; it secreted one litre of pus daily. He resected the ribs from the sixth to the tenth extensively, separated the partition wall between the various cavities without hæmorrhage, and, lastly, resected the whole lower lobe.

For the prevention of pneumothorax he recommended the introduction of a large piece of gauze into the pleural cavity as soon as the lung sank back.

Hr. Baginsky related a case of

Septic Arteritis and Aneurysm

in a child. A child of 7 was admitted into hospital in a state of high fever. Nothing was found beyond a slight murmur at the apex of the heart. Some days later a rigor occurred, and from that time for some weeks there was continuous septic fever. One day a tumour was felt below the umbilicus, but it did not pulsate. A short time afterwards the radial pulse suddenly ceased. Two months later pulsation was felt in the tumour. A diagnosis was now made of aneurysm of the abdominal aorta. Shortly afterwards cerebral symptoms appeared, soon followed by a fatal termination.

No sign of syphilis appeared either in the history or at the autopsy. There was an abdominal aneurysm with infarcts in the kidneys and spleen. The disease in the aorta appeared to have started in the media. Pure cultivations of streptococci were present in the thrombi, filling the vessels, and even in the diseased walls. It was a case of septic arteritis, a very rare affection in children. (The preparations were shown.)

AUSTRIA.

Vienna, March 15th, 1908.

Myxœdema.

At the Gesellschaft, Moszkowicz exhibited a six-year child who suffered from myxœdema when an infant through thyreoaplasia. When 3 months old he inserted a piece of thyroid gland 3 or 4 cubic centimetres in size, which had been taken from a patient that had been operated on for goître in the tibia. After this implantation the child rapidly improved in general appearance and psychic movements, the cranium having increased 2 centimetres, = .79 in. This improvement he assigned to the absorption of the gland, and as the improvement has continued, it is fair to assume that the function has been supplanted by the insertion of the gland portion.

His reason for selecting the medullary substance of the tibia was owing to the frequency of metastasis that occurs here in adenomatous carcinoma, resembling thyroid, which he surmised had some affinity to the gland. He was not alone in this opinion, as Payr supported this view that the circulation in the marrow of the bone was more favourable to this operation than the spleen.

Eiselsberg said he had selected a position between the fascia and peritoneum, thus following the example of animal experiments which always do well. He thinks the tibia a much better place to implant than the spleen, no matter how much may be urged theoretically in favour of the latter; but the reason given by Moszkowicz for implanting in the tibia is not a rational one, and he would pause to consider the results before giving an authoritative opinion on the subject.

Biedl said he was in favour of the transplantation method of Moszkowicz, because he found in his experiments on animals that the transplanted sections were better nourished, owing to the better blood supply and firmer support than they had in the spleen or peritoneum. It is certainly much better than the subfacial implantation, and more vascular.

Mongol Habitus.

Knöpfelmacher next exhibited an interesting case of erythrodermia desquamativa in a child 3 months old. It had a blue mark, resembling a cross, on the sacrum and ischial surfaces, which was typical of the Mongolian race. In European children this mark is a very rare thing, though sometimes to be met with beside the Mongolian and Malayan races. The prognosis in this case, he thought, was hopeless.

Ankylosis and Contractions.

Jerusalem gave a report of his experiments with the Bier-Klapp apparatus, which is worked as an air-pump by extracting the air and correcting the contraction. He had applied it in 35 cases during the year, 10 of whom were perfectly cured, while the others were more or less improved. Röntgen photographs were produced. His experience led him to the conclusion that the knee and elbow-joints were the hardest to move when ankylosed. The pressure of air in these cases was often so great as to cause paralysis of the limb, which he obviated by bandaging the extremity well before operating, and then firmly fixing the limb in the apparatus before the air is extracted. To guide the operator he has devised an arthrometer to measure the excursion of the joint towards the normal position.

Bum said he preferred the mobilising of the syndesmosis with the hand, as you could better judge of the straining and injury that could be done by such a powerful machine as that shown. He always found these ankyloses yield better by associating Bier's congestive treatment with the stretching which greatly reduces the pain and supplies more nutrition to the stiffened joint. When the adhesions are too strong, it is then necessary to resort to stronger measures, but, as a rule, he could manage with the hand.

Jerusalem said he had as delicate a control with Bier's apparatus as with the hand, as the instrument is fitted with glass fenestra for observing the hyperæmia and pressure exerted on the limb. The force can be more regularly and gradually applied than with the hand.

Genital Malformation.

Lichtenstern exhibited a young man, æt. 25, with a double scrotum, one at each of the annulus inguinalis externus overhanging a hypoplastic penis. The seminal cords issued from the inguinal canals, with a curve towards the symphysis, and suddenly turned outwards to enter the scrota, under which lay a penis 5 to 6 centimetres, or 1.9 to 2.3 in., and directed outwards according to the patient's own story.

Perforation of Nasal Septum.

Goldreich showed a six-months child with hereditary syphilis and perforation of the nasal septum, which is a rare condition in a child so young. It did not appear to be the result of a single gumma, but rather an inflammatory hyperplastic process in the mucosa, which subsequently acted on the perichondrium and cartilage.

HUNGARY.

Budapest, March 15th, 1908.

At the last meeting of the Society of Physicians, Dr. Rosenberg reported on some

Sequelæ Resulting from the Use of Adrenalin.

The patient, a young woman in good physical condition, presented what appeared to be symptoms of an accessory nasal sinusitis. A small swab saturated with suprarenal extract was applied to the swollen inferior turbinate. It brought on an unpleasant disturbance of smell, and within a few hours was followed by a diffuse urticaria extending over the trunk and arms. This disappeared after a short time, but about a week later, when the treatment was repeated, the same trouble reappeared. Swabs saturated with water or cocaine failed to produce the same effect. Dr. Rosenberg believes that this urticaria was caused either by absorption of the drug or was a reflex disturbance brought about by an irritation of the olfactory nerve, the patient complaining of an unpleasant sensation of smell at the time when the adrenalin was applied.

Dr. Kryte read a paper on

The Pathological Anatomy of Epilepsy.

In a case where epilepsy had proved fatal, he found the cortex of the brain the seat of a number of cavernous angiomata, the largest of which were surrounded by calcified connective tissue. They were probably congenital, since the epileptic seizures began in earliest youth. Their relation to epilepsy can hardly be explained by variations in intracerebral blood pressure, since experimental venous stasis, even in epileptics, never brings about an attack, and since compression of the carotids in animals is never followed by convulsions. It is more probable that they irritate the cortex by their constant growth. Angiomata of the brain are rather rare, but have been found in several previously reported cases of epilepsy.

Dr. Hollos read a paper on

The Influence of the Alcoholism of Parents on their Children.

It is a well-recognised factor in pathology that the habitual parental inebriety has a pernicious influence on the offspring, and statistics seem to show that this cause is vastly more operative when, of the two parents, the mother is the drunkard. This, indeed, is only what one would anticipate, seeing that for nine months the fœtus remains exposed to the perilous influence of the alcohol taken persistently. Sobriety on the part of the father has but little effect so far as the health and vitality of the child is concerned, and, in presence of maternal drunkenness, may at most be discarded, although, no doubt, the result of the two bad strains would intensify the consequent mischief. The influence of chronic parental inebriety in this connection bears mainly on the higher department of the nervous system, producing more or less marked intellectual inferiority and a functional incapacity on the part of what may be described generally as the moral functions of the brain. For instance, the children of drunken mothers have but an imperfect conception of the moral obligation of honesty, truth, etc., in spite of careful training, which, by the way, they do not usually get. Their emotions and passions cannot be brought under adequate control; consequently, they furnish a large contingent to the criminal and to the so-called irresponsible classes. Looked at from this point of view, it becomes obvious that criminal tendencies are of the nature of a constitutional disease, to be dealt with preventively and therapeutically.

The Presence of Koplik's Spot in Measles.

Dr. Roth has looked for the spots on the buccal mucous membrane, first described by Koplik, as preceding by some days the general eruption of measles, and has found them in 22 cases. In 1 case they preceded the eruption by six hours, in 11 cases by one day, in 5 by two days, in 3 by 1½ days, and in 2 by four days. The spots were generally situated on the mucous membrane of the cheeks opposite the molar teeth, but occasionally on the lips, beginning as slightly raised, bluish-white, circular, sharply defined points, in size less than a pin's head, and surrounded by a narrow red areola. In a few days they generally increase slightly, and become more prominent, and the areola enlarges and becomes more irregular in outline. Their number varied between 6 and 20, and the time during which they persisted from two to six days. They were not marked just before, or at the time of the general eruption. They were not present in 14 cases. Since they were never seen in other conditions not accompanied by fever, they are of the greatest importance for the early diagnosis of measles. Roth claims that the buccal eruption in measles was first mentioned by Gerhardt, and that their importance was recognised by Filutow in 1895, a year before their independent discovery by Koplik.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Extra-Mural Teaching in Glasgow.—Since Mr. Andrew Carnegie provided a fund for the payment of students' fees, the prosperity of some of the Extra-Mural Schools of Medicine in Glasgow has decreased. St. Mungo's College, especially, which is the teaching school in connection with the Glasgow Royal Infirmary, appears to have suffered greatly. And, as it is desirable that the Royal Infirmary be in close contact with a medical school, a deputation consisting of some of the governors of the Royal Infirmary and of St. Mungo's College approached the Glasgow University Court last Thursday, for the purpose of laying the claims of both of those institutions before the University authorities, with the desire that the University may see their way to take advantage of the rich clinical material in the Royal Infirmary for the clinical instruction of the students. It is an admitted fact, that the classes in the Western Infirmary are congested, and this congestion might be relieved by utilising the wards of the Royal Infirmary. Thereafter, a committee, consisting of Principal McAllister, Sir Hector Cameron, and others was appointed to look into the matter and report to the Council.

Vacant Professorial Chairs.—The chair of the Practice of Medicine in the University has not yet been filled up, and the profession are keenly awaiting the news of the appointment. We understand Dr. Gibson, of Edinburgh, has retired from the contest, so that there is reason to believe a Glasgow man may be appointed.

The chair of Medical Jurisprudence in Anderson's College has been recently advertised. Dr. Carstairs Douglas recently taught there both forensic medicine and public health. He desires to confine his attention to public health, and an attempt is being made to have a teacher for Forensic Medicine pure and simple.

The Ruchill Hospital Inquiry.—The Commissioners' report on Ruchill Fever Hospital was the subject of a long debate in Glasgow Town Council on Thursday last. After a fruitless discussion, the whole matter has been referred back to the Hospitals' Committee. One gentleman proposed an amendment that the dismissed doctors be reinstated, but he was induced to withdraw his amendment. The redoubtable Mr. Andrew Scott Gibson wished to probe the whole matter to the bottom, but we must wait on the Committee's next report to the Council.

Medical Justices of the Peace.—Among names lately added to the Commission of the Peace for the County of Aberdeen upon the recommendation of the Lord Lieutenant, the following members of the medical profession occur:—Dr. Robert Bruce, Cults; Dr. John Findlay, Lonmay; Dr. Edward Oliphant, Buckburn; Sir James Reid, Bart., Ellon; Dr. Alex. Trail, Fraserburgh; Dr. E. R. Turner, Kintore.

County of Fife Medical Officership.—Dr. Naismith's place has been filled by the election of Dr. T. F. Dewar, Medical Officer for the County of Forfar. Dr. Dewar is an Aberdeen graduate; he is a medical officer to the Fife Imperial Yeomanry, and served with distinction during the late campaign in South Africa.

Administration of Falkirk Fever Hospital.—The Commissioners, who some time ago held a public inquiry into the affairs of this hospital, have now issued their conclusions and recommendations. In homologating there the Local Government Board express their satisfaction with the efficiency of the hospital as now reorganised. The Commissioners found that prior to May, 1907, the administration was unsatisfactory in respect of the failure to provide the nursing asked by the Medical Officer, the insufficient checking of the use of alcohol, the laxness and inefficiency of the matron, and the preservation of discipline and admission of visitors. They recommend that the Medical Officer should be the responsible head, and responsible only to a committee of the Town Council; that visiting should be restricted to the members of the committee. The charges brought by Mr. Miskimmin, beyond the above, have not been substantiated, and there is no evidence bearing out the statements made concerning one of the city officials and a medical man in the town.

BELFAST.

The Serum Treatment of Cerebro-Spinal Meningitis.—At a meeting of the Public Health Committee held last week, Dr. Gardner Robb reported the results obtained up to date by the use of Flexner's serum. Since September 1st last year, all cases of cerebrospinal meningitis admitted to Purdysburn fever hospital have been treated with this serum. The total number of cases is now over 70. In the first 50 of these which have been treated to a conclusion, 13 died and 37 recovered, giving a case mortality of 26 per cent. Before using the serum the number of cases in hospital was 275, and the death-rate in these was 72 per cent. So far as Dr. Robb could judge, he thought there was no improvement in the type of the disease.

The Irish University Question.—A debate on the Irish University question was held last week at the Presbyterian Theological College in Belfast, and was specially interesting as showing the views of the rising generation of the Presbyterian clergy. The opener of the debate advocated the scheme generally looked upon as Mr. Birrell's, a new University controlled by the Roman Catholic authorities, but open to all, in Dublin, and a new Northern University in Belfast, while Dublin University should be left untouched. The leader of the opposition advocated the formation of one National University for all Ireland. No vote was taken, but it was evident that there was a considerable body of opinion in favour of an Ulster University, and a growing faith in its possibility. There was also a noteworthy disposition to recognise the fact that the Roman Catholic Church's objection to mixed education must be allowed, and University affairs arranged accordingly. This is a decided advance on the attitude generally adopted in the Presbyterian Church a year or two ago.

Nature Study.—The Lion and Jackal.—At the meeting of the Ulster Medical Society, held on Thursday last, the evening opened with a short paper by Mr. R. J. Johnstone on "The Lion and the Jackal: A Nature Study." In the form of a thinly-veiled allegory he dealt with the burning question of the relations between the consultant and general practitioner, and displayed an amount of wit, wisdom and common sense that delighted his audience. He divided the genus Leo into two species, Leo sectator and Leo scrutator, and described the habits of each, and the manner in which the jackals helped them in the capture of their prey. The fat old lions, who never attended the meetings of the jungle folk, and the hungry young lions who did most of the roaring at the meetings, were in turn described, and the question of hospital abuse was discussed under the guise of an account of the sanctuaries into which the natural prey of the lion was admitted when too thin and mangy to afford a decent meal, though, as it was remarked, the jackals often thought they might have been allowed another bite before the lions passed the prey into the sanctuary!

LETTERS TO THE EDITOR.

WORKMEN'S COMPENSATION ACTS.

To the Editor of The Medical Press and Circular.

Sir,—I notice in your Notes and Comments you raise the question "Where a workman should attend for examination?" Under the Workmen's Compensation Acts (Sec. 60 and 61 Vict., cap. 37, Schedule I., Section 11) a workman must attend at the consulting room of the medical practitioner selected by the employer, unless in the opinion of his own medical attendant he is unable to travel.

I am, Sir, yours truly,
Robert Saundby.

140b, Great Charles Street, Birmingham.
March 12th, 1908.

[We are obliged to Dr. Saundby for his letter, but may we remind him that the Workmen's Compensation Act, 1906, 6 Edw. 7, consolidated the previous Law on the subject, as well as amended it. The obligation does not appear in the new Act nor in any of its Schedules. At the moment of going to press we are not able to state if it occurs in any of the rules under the Act, but our memory is that it does not.—Ed.]

THE STUDY OF TWINS AND "DOUBLES."

To the Editor of The Medical Press and Circular.

Sir,—May I trouble you to insert a further letter of inquiry on a point I raised a few months ago in your columns in reference to diseases of twins?

Many of your readers were obliging enough to reply to my inquiries, and I have now a considerable quantity of evidence on this subject, though I should be very glad of additional material.

A further question I would wish to have medical experience upon is that of similarity of diseases in persons not brothers nor sisters, and yet greatly resembling each other.

From time to time popular magazines have published photographic reproductions of these resemblances, and instances of odd mistakes are now and again commented on in daily newspapers and elsewhere. The popular saying that "every person has his double" records the general recognition of this fact.

The evidence which I now possess makes it probable that twins suffer similarly from disease, and that constitution is a much more important factor than has lately been assumed, the older medical men being largely justified in their insistence upon this.

Before, however, giving facts to support such a conclusion, I am anxious to obtain an independent source of study to compare with my twin researches, and the possibility of the availability of "doubles" has been brought into my mind by a case in my own experience, which was as follows:—

A colleague of mine and myself both mistook a new patient we had not previously seen for an old one suffering from diabetes, so alike were they in appearance; and at our request she brought up a sample of urine to be examined, and it was diabetic. The woman herself had no suspicion at the time of this disease, nor had she any noticeable symptoms, and, but for the chance likeness to the other patient, the disorder might very possibly have been overlooked.

If any other medical men have similar experiences I should be glad if they would kindly communicate with the writer at the address appended below, or through your hospitable columns.

I am, Sir, yours truly,
J. Lionel Tayler.

8, Adys Lawn, St. Paul's Avenue,
Willesden Green, N.W.

CHRISTIAN SCIENCE.

To the Editor of The Medical Press and Circular.

Sir,—On unquestionable authority, I learn that Mr. Dixon's letters in your pages have attracted attention widely, and have done much to discredit his teaching; and I have been informed of at least one case in which they have prevented a patient afflicted with a disease easily curable by surgery from putting his trust in miracle-mongers, and have induced him to undergo the simple operation certain at once to give relief to his sufferings and put an end to an otherwise fatal malady. If you could only induce Mr. Dixon to continue, and could bring his writings before those of the public able to appraise their value, a great deal might be done to dispel illusions which are undoubtedly giving rise to much suffering and misery. Nothing could be more harmful to Mr. Dixon than his unfounded charge that he is abused by those who expose his fallacies—a charge which he repeats to-day. If you will allow me, I will recapitulate some of my chief statements, and with this I shall be glad to end my contributions to the debate.

I pointed out, first, that the conception of the Deity put forth by Christian Science is necessarily blasphemous in the estimation of every enlightened religion, in that it degrades Divine Providence to the level of an African fetish—a household god which bestows its favours on those alone who know how to propitiate it by the prayers and ceremonies which it loves. Although the knowledge of the merest tyro is not needed to expose the sophistries of Mr. Dixon's theology, it has not been necessary for my purpose to examine into it at length. It has sufficed to point out that out of his theology arises the claim to cure all diseases by miracle. This claim is supported by a newly-invented tissue of transcendental pseudo-metaphysics, a grotesque travesty of legitimate philosophical speculations on the ultimate nature of matter and force. To deal with these utterances seriously is impossible—it is more futile than beating the air; they are fit only for ridicule. In so far as they bear upon the cure of disease they could be listened to only by those entirely ignorant of physiology—the structure and functions of the body in health—and of pathology—the changes which take place in the organism during disease. Whatever be the ultimate nature of matter and force, we cannot by prayer without human agency provide food and convey it into the stomach of a starving man, however devout he be. It would be miraculous; but not more miraculous than the expulsion by the same means of a group of hydatids from the liver, a mass of tapeworm from the intestines, or a colony of itch insects from the dermal tissues. Mr. Dixon seems to know little about such comparatively simple maladies, and less about "consumption, cancer and epilepsy," which, he says, are being "destroyed" daily by Christian Science He looks upon these diseases as distinct entities, to be exorcised and driven out of the body by the methods of mediæval thaumaturgy. By consumption he no doubt means pulmonary tuberculosis. Does he pretend that the cavities caused by the destruction of lung substance can be repaired and filled with new tissue by means of prayer and the pious emotion of the patient?

Then, again, many distinct varieties of malignant growth are classed as cancer; the phenomena presented during the invasion of different organs and tissues are extremely complex, so that no one with a rudimentary knowledge of the subject can fail to realise the miracle which "destruction" of these products by Christian Science would imply. Then, for another illustration, epilepsy presents several totally distinct varieties. If any one kind is purely psychic, perhaps Christian Science may influence it; but it is inconceivable that epileptic fits due to a gumma in the brain, or to the pressure of a depressed fracture, with perhaps a spiculum of bone penetrating the cerebral substance, should be curable by such methods—it would be a miracle. Imagine the misery that may result if patients, relying upon Christian Science in such cases as the last, refuse anti-syphilitic treatment or the surgical operation which so often provide the means of relief and cure. Then, as a last example, we may consider the vast range of diseases due to degeneration. To restore the tissues of a kidney in advanced chronic nephritis, or of a spinal cord in advanced sclerosis, to restore these obliterated tissues to functional activity would surely constitute a miracle hardly less stupendous than to raise to life a putrefying corpse. If Christian Science can do the one, it can surely do the other. Lastly, when Mr. Dixon speaks of the rapid spread of Christian Science, he forgets Joe Smith the Mormon Prophet, Dowie of Zion City, and the whole army of smaller and bigger inspired preachers of the same sort, whose progress for a time was much more wonderful than that of which the new cult can boast. The former bubbles have been pricked, and have collapsed; *magna est veritas et prævalebit.*

I am, Sir, yours truly,
Henry Sewill.

March 11th, 1908.

[Correspondence on this subject must now cease.—Ed.]

VACCINATION AND THE MEDICAL PROFESSION.

To the Editor of The Medical Press and Circular.

Sir,—The question raised by Mr. Swan in your issue of the 4th inst. really has no bearing on the matter under discussion. We are concerned with facts, not theories, and explanations can be dispensed with in view of the unquestionable fact that vaccination *does* protect against small-pox, as Mr. Swan concedes in his second paragraph. I can no more explain why it does so than why quinine arrests malaria, mercury syphilis, and so on.

As a matter of fact, vaccination does in some measure protect against itself in that a large proportion of re-vaccinations at an early date prove negative, and, when successful, the resulting serum is comparatively inert—but all this is beside the mark.

The duration of the protection afforded by vaccination no doubt varies in different individuals, just as does the immunity created by an attack of typhoid or scarlet fever to these diseases respectively; but the evidence at our disposal justifies the belief that it is much longer than the period so confidently stated by your correspondent.

I am, Sir, yours truly,
Alfred S. Gubb, M.D.

Algiers, March 12th, 1908.

OBITUARY.

HALLIDAY DOUGAS, M.D., ED., F.R.C.P.

The death occurred on the 10th inst., at his residence, Park Crescent, Edinburgh, of Dr. Andrew Halliday Douglas, Senior Fellow on the roll of the Royal College of Physicians, Edinburgh, as a practitioner. A son of Mr. William Douglas, W.S., Edinburgh, he was born in 1819, and was thus in his eighty-ninth year. He was educated at the High School of Edinburgh. In 1835 he entered the University of Edinburgh, and graduated in medicine in 1840. Three years later he became a Fellow of the Royal College of Physicians, and in the same year, 1843, at the age of 24, he was appointed ordinary physician to the Edinburgh Royal Infirmary. During the tenure of his office in the infirmary, and for some years subsequently, he had a considerable practice as a consultant, and among other posts filled by him was that of Physician to the Chalmers Hospital and Medical Officer to the General Post Office. He held the latter appointment from its inception for a period of about 40 years, and resigned it in October, 1897. For many years Dr. Douglas was Treasurer of the Royal College of Physicians, and in 1870 held the office of President of the College. Dr. Douglas was specially interested in the pathology and treatment of heart disease, and wrote one or two monographs on that subject. He also made a special study of relapsing fever, which was epidemic in Edinburgh in 1843. In 1890 Dr. Douglas retired from active work, and since that time resided partly in the country. His eldest son, Dr. Kenneth M. Douglas, succeeded him in practice in Edinburgh. His second surviving son is Mr. Charles M. Douglas, of Auchlochan, formerly M.P. for North-West Lanarkshire. His second son, the Rev. Professor Halliday Douglas, of Knox College, Toronto, predeceased him in 1902.

THOMAS DEAN, M.D.St.And., M.R.C.S.

We regret to learn that Burnley has lost one of its most familiar figures by the death of Dr. Thomas Dean, who died at his residence on March 11th, after a brief illness. He had been in failing health for some months past, but a week last Monday he was attending to his duties as Medical Inspector of Factories. The deceased gentleman was one of the oldest medical men in East Lancashire, and he was certainly the oldest in the Burnley district. Born at Slaithwaite, Yorkshire, in 1833, he came to Burnley over half a century ago. For over 30 years he acted as Medical Officer for the borough, retiring some few years ago, and for over 20 years he had been the Certifying Surgeon to the Factories. In years gone by the Liberal cause found in him a zealous worker, and he was a Vice-President of the Burnley Liberal Association. He took a great interest in the Burnley Literary and Scientific Society, and he has lectured before the society on the "Place Names of Burnley," on which subject he was the recognised authority. He was a genial and most highly respected gentleman.

EDWARD ROBERT BICKERSTETH, F.R.C.S.Eng. and Ed.

It is with much regret we record the death of Mr. Edward Robert Bickersteth, which took place on March 7th at his Liverpool residence, at the ripe age of eighty. The family to which Mr. Bickersteth belonged was well known for many generations in South Lancashire. His grandfather, a medical gentleman, had four sons. Of these, one was the Rev. Edward Bickersteth, vicar of Walton, Herts, whose son became Bishop of Exeter. Another, who went to the Bar, became the famous Lord Langdale, Master of the Rolls; a third, the Rev. John Bickersteth, vicar of Sepcott, Leeds, was father of the late Dean of Lichfield, and of the late Bishop of Ripon. A son of the Bishop of Exeter, just named, became Bishop of Japan. His fourth son, Mr. Robert Bickersteth, father of Mr. E. R. Bickersteth, was surgeon, and afterwards consulting surgeon of the Liverpool Royal Infirmary. Mr. E. R. Bickersteth's medical studies, commencing in the Liverpool School of Medicine in 1845, were afterwards pursued in Edinburgh, London, Dublin, and Paris. After obtaining his diploma as member of the Royal College of Surgeons, England, he returned to Edinburgh, and he had the honour of being elected by Professor Syme as his house surgeon. In 1852 he began general practice in Liverpool, according to the almost invariable provincial custom of that time; but his predilection for surgery was so strong that in 1857, finding no surgical appointment vacant, he established a private hospital, which attracted considerable attention from the public and the profession, and led to his appointment, at the age of twenty-eight, as surgeon to the Royal Infirmary. For many years also he conducted a course of lectures on systematic surgery in connection with the Liverpool School of Medicine. Although the responsibilities of a large consulting practice, extending over a very wide district, had curtailed the time at his own private disposal, he found opportunity during his earlier career, extending to the early seventies, to contribute upwards of twenty papers recording his experiences. From that time onwards his services were so much in demand that his opportunities for adding to these enrichments were practically nil. The Liverpool Royal Infirmary may be said to have enjoyed the services of the Bickersteths, father and son, for almost a century, Mr. Robert Bickersteth having served it as operating surgeon from 1811 to 1853, and Mr. E. R. Bickersteth from 1856 to 1888. At the close of his career as surgeon to the institution named, the subject of this memoir was appointed consulting surgeon, a position he held till his death. A remarkable indefatigable worker while on duty, he annually enjoyed a summer holiday, which he generally spent in yachting, and to that was largely attributable the excellent health he so long enjoyed.

WILLIAM CLARKSON, L.R.C.P.ED., L.F.P.S.GLAS.

WE regret to record the death of Dr. W. Clarkson, who was buried at Morpeth on March 10th, and who, in addition to having a large private practice, had held many public medical appointments, and was an ex-Mayor of the town. He was 78 years of age, and obtained his first qualification, the L.F.P.S. of Glasgow, as long ago as 1856. The funeral was attended by the Mayor and members of the Town Council, in addition to representatives of numerous other private bodies.

REVIEWS OF BOOKS.

HYPNOTISM AND SUGGESTION.

IT is more than seven years since (August 1st, 1900) we reviewed the fourth edition of Dr. Lloyd Tuckey's book on "Treatment by Hypnotism and Suggestion." In the time that has since elapsed there has been curiously little added to our knowledge of the subject, but that little has not escaped Dr. Tuckey's notice, and consequently the fifth edition (*a*) of his book, recently published, will be found to contain the most recent information. In commenting on the previous edition, we said that "hypnotism has established its right of therapeutic tenure." Of this there is, of course, no doubt, but, at the same time, it is not to the credit of the medical profession that the exercise of hypnotism as a therapeutic agency has been left so much to the quack and the enthusiast. While the medical use of hypnotism and suggestion has grown but little during the past half-dozen years, the various sects of faith-healers and Christian Scientists whose methods depend on suggestion have flourished greatly.

In the present volume Dr. Tuckey claims for suggestive treatment its proper place, not as an exclusive method, but as an important weapon in the physician's armamentarium. He makes clear, by reference to actual cases in his own practice, and in the practice of others, the classes of disease which are likely to be benefited by this method of treatment. In particular he shows that various drug-habits, and other evil habits, may be cured by hypnotic suggestion when all other treatment has proved ineffective. At the same time he is laudably frank in admitting his failures, and he writes in the cautious spirit of a man of experience as well as of a man of science.

His directions as to the methods he himself finds most useful are clear and precise, while he does not attempt to tie individual physicians within a definite set of rules. Individual cases will require individual treatment, and the physician must use his discretion as to the methods he will employ.

Dr. Tuckey writes in pleasant, chatty narrative style, and his book is one which a reader will find convenient to take up at any moment. His knowledge of his subject is thorough, and his own views are constantly supported by references to the literature as well as to the records of his own extensive practice.

It is unnecessary to recommend a book already in its fifth edition.

PRECIOUS STONES FOR CURATIVE WEAR. (*a*)

FROM time immemorial gems and precious stones have exercised a fascination for men and women which cannot be adequately explained by their intrinsic value or even by their beauty. The book before us purports to offer as an explanation for this fact that such precious stones when worn as jewellery can, and do, exercise a direct physical influence over the life and health of the lucky possessor. Such teaching was, of course, almost universally accepted in the Middle Ages, and it would seem that the discovery of the therapeutic action of radio-active substances in recent years is tending to cause its readoption. The great advances of physical sciences has in no way killed the superstitious beliefs of the majority of the people, and even the most slender basis of physical science is gladly welcomed by them as a justification for the practices which result from such beliefs. With such a subject our author has ample material for a most interesting book, and we can only regret that he has not made better use of it. Where he confines himself to the description of the gems or the history of their uses in medicine in the past he is interesting, but the numerous repetitions and the long extracts from the novels of Dickens and other authors make the extraction of the interesting paragraphs not a little tedious. Much, however, we suppose must be forgiven to a medical author who believes that the wearing of a diamond ring is a preventive "against a disposition to acid, flatulent indigestion," and that the suspension of a disc of copper against the skin of the abdomen will prevent infection by the cholera vibrio.

CARDIAC AFFECTIONS. (*b*)

AMONG the new volumes constituting the series of "Oxford Medical Manuals," Dr. Poynton's work is one of the best. It is an excellent example of concise yet comprehensive presentation of a peculiarly difficult and almost unlimited subject. By judicious grouping, clear exposition, and a real knowledge of the needs of the young practitioner, the author has been enabled to gather into this pocket manual a serviceable description of the more important forms of cardiac lesion, with indications as to the best means for their clinical investigation and effective treatment. As would be expected from such an investigator as Dr. Poynton, special attention is devoted to what are considered the "rheumatic" affections of the heart; but throughout there is a fair and broad-minded presentation of points, and personal views and predilections are not unduly urged. The work is primarily intended for the inexperienced practitioner, and for such it will be invaluable, but it contains much which will be of suggestive value even to the cardiac "specialist." The former will welcome the numerous prescriptions and notes on diet, Schott movements and preparation of Nauheim baths, and the latter will be particularly interested in the well-executed series of illustrations dealing with pathological conditions. Dr. Poynton has accomplished a difficult task with conspicuous success.

AT the joint half-yearly conference of representatives of societies and institutions engaged in social service held in the Onward Buildings, Manchester, Principal J. W. Graham in the chair, a resolution was passed unanimously trusting "that the Notification of Births Act will shortly be adopted in Manchester; subject to such changes in administration as may be agreed on," and suggesting that the notice might go to the Registrar, the Registrar communicating frequently with the Medical Officer of Health.

FORTY new cases of bubonic plague have occurred at Antofagasta during the last few days.

(a) "Treatment by Hypnotism and Suggestion, or Psycho-Therapeutics." By C. Lloyd Tuckey, M.D.Aberd.; Membre Fondateur de la Société d'Hypnologie; President of the Medical Society for the Study of Therapeutic Suggestions, &c. Fifth Edition, revised and enlarged, with an introductory chapter by Sir Francis R. Cruise, M.D., D.L., K.S.G., Honorary Physician to the King in Ireland. Pp. xxviii and 418. London: Bailliere, Tindall and Cox. 1907.

(*a*) "Precious Stones for Curative Wear: and other Remedial Uses; likewise the Nobler Metals." By W. T. Fernie, M.D. 8vo. Pp. xviii. and 486. Bristol: John Wright and Co. 1907.

(*b*) "Heart Disease and Thoracic Aneurysm." By F. J. Poynton, M.D., F.R.C.P., Assistant Physician to University College Hospital. Pp. 310, with xvii plates and 20 figures. London: Henry Frowde and Hodder and Stoughton. 1907. Price 5s. net.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT PATHOLOGICAL LITERATURE.

Adrenalytic and Thymolytic Sera.—Ritchie has endeavoured to produce specific antisera from the adrenal and thymus glands, working principally with ducks and guinea-pigs (*Journal of Pathology*, January, 1908, p. 140), and has partially succeeded. He summarises his results as follows:—(1) The serum obtained from ducks which have been treated with guinea-pigs' adrenals contains an adrenaphilic immune body, which in the presence of guinea-pigs' complement becomes fixed to guinea-pigs' adrenals. (2) The serum is not strictly specific, but there is no evidence of it being hæmolytic. (3) The serum, although adrenaphilic, was not adrenalytic. (4) The adrenaphilic immune body was thermostabile at 51° C., but not at 57° C. With the thymus gland Ritchie was enabled to obtain a leucolytic serum, of which he gives the following account:—(1) The serum obtained from ducks which had been treated with the thymus gland of guinea-pigs contained a leucophilic immune body. (2) In the presence of this immune body, guinea-pigs' complement became fixed to guinea-pigs' thymus, lymphatic gland, bone-marrow and spleen. (3) The serum was not hæmolytic. (4) The structural changes in the thymus of the guinea-pig following injection of the serum were due to its leucolytic action, and are not specific.

M.

Leucocytosis in Diphtheria.—Dean has carried out some interesting investigations on the leucocytosis of diphtheria, and the modifications observed in the blood after the injection of antitoxin. He has worked both with patients suffering from diphtheria, and also experimentally with rabbits (*Journal of Pathology*, January, 1908, p. 154). He gives the following main conclusions:—(1) After the experimental injection of diphtheria toxin there is a great increase in the total number of leucocytes; this increase is due to the appearance in the blood of enormous numbers of polynuclear cells. (2) After the injection of diphtheria toxin, degenerative changes can be demonstrated in both the white and the red cells. In the latter polychromatophilia is well shown. The eosinophile cells usually completely disappear. No myelocytes are seen. (3) The changes following experimental injection of toxin are similar to those seen in cases of diphtheria occurring in the human subject. (4) A dose of antitoxin, which, when given simultaneously with the toxin, completely protects the animal under observation, prevents the appearance of a leucocytosis. Similarly, when a sufficient dose of antitoxin is given shortly after the injection of the toxin, the number of leucocytes rapidly falls to normal. (5) When a considerable interval is allowed to elapse between the injection of toxin and the injection of antitoxin, no reduction in the leucocytes occurs. (6) In two clinical cases the interval between the onset of the disease and the employment of antitoxin was relatively short, and in these cases a considerable reduction in the leucocytosis appeared to follow the use of antitoxin. (7) No reduction was observed in four other cases in which a relatively longer time had elapsed between the onset of symptoms and the use of antitoxin. (8) A marked reduction in the leucocytosis occurring within the first 24 hours after the injection of antitoxin probably indicates a good prognosis. (9) A sufficient dose of antitoxin completely protects the blood cells from degenerative change.

M.

New Growths of the Testicle.—Nicholson presents an elaborate study of new growths of the testis, based on an examination of 65 cases (*Guy's Hosp. Reports*, Vol. LXI., p. 249). His conclusions are as follows:—(1) The only form of carcinoma met with was spheroidal-celled. This was in almost every case encephaloid in character, and was both alveolar and non-alveolar. It is frequently mistaken for sarcoma, and may be met with at an early age. It is clinically malignant, and is the second most common variety of tumour met with. (2) The sarcomata met with are usually round-celled. They are more malignant than the cancers, and are met with at an earlier age. They are occasionally bilateral, and appear to disseminate by the blood-vessels, as distinguished from carcinomata, which spread by the lymphatics. (3) Endotheliomata arise from the endothelium of the blood-vessels or lymphatics. They occur most often in young adults, and usually run a benign course. They may, however, produce metastatic growths in lymph glands. (4) Embryomata are the commonest form of new growth in the testis. They contain structures from the three blastodermic layers of the embryo. Although not necessarily malignant, they may produce metastasis of all the tissues of the primary growth, or one tissue may become actively malignant, in which case the deposits will be formed from that tissue alone. (5) Some embryomata contain trophoblast derived from the epiblast of the primary growth. In these cases the trophoblast assumes malignant characters and forms secondary growths. The trophoblast may assume a form resembling carcinoma, sarcoma, or endothelioma.

M.

Typhoid Carriers.—The term "typhoid carrier" has been applied during the past few years to people who, having once suffered from typhoid fever, retain the typhoid bacilli in their bodies after their return to health, and may, therefore, act as distributing agents of the infection. This condition may last for several years. A. and J. C. G. Ledingham report (*British Medical Journal*, January 4th, 1908) an investigation into the cause of typhoid in an asylum in Scotland, in the course of which they discovered three "typhoid carriers." Ever since 1893 the asylum in question, a small one, with a population of about 150, had been subject to outbreaks of typhoid fever. Thirty-one cases had occurred, 24 of the patients being females. The water and milk supplies were shown to be pure, and the drainage system excellent. Examination of the blood and fæces of all the female patients, some 90 in number, was made. It was discovered that three not only gave a positive Widal reaction, but exhibited large numbers of typhoid bacilli in the stools. The typhoid bacilli had grown almost to the exclusion of other germs, and were more plentiful than *b. coli*. One of the patients had certainly not had typhoid fever since 1896, another had it in 1895, and the third in 1904. Dean publishes (*British Medical Journal*, Maroh 7th, 1908) a remarkable case of a "typhoid carrier," where infection apparently persisted for 29 years. The patient, a medical man, had, at that distant period, suffered from typhoid fever. Ever since, though as a rule his health was good, he had been subject to occasional attacks of biliary colic, sometimes accompanied by jaundice. The Widal test with his blood was doubtful, but typhoid bacilli were present in the fæces in enormous numbers, being more plentiful even than *b. coli*. The importance of such cases from the public health point of view is great, as "typhoid carriers," especially those employed in certain occupations, may disseminate infection far and wide. It is supposed that in the "typhoid carrier" the germs are present and multiply in the gall-bladder, making their way into the intestine with the bile.

R.

Experimental Bone Formation.—The formation of bone in abnormal situations has long been a familiar phenomenon in certain pathological processes. It is only recently, however, that bone has been produced as the result of experiment. Harvey publishes (*Journal of Medical Research*, October, 1907) a description of certain experiments which demonstrate that the process can be carried on without difficulty. He exposed the aortas of rabbits to the action of a strong irritant—silver nitrate or copper sulphate—and in five out of ten experiments bone was produced in the middle coat of the vessel. In three others bone-like tissue, but not calcified, was found. The bone formation took place in the tissue previously necrosed, and was a sequel of extreme calcareous degeneration. In some of the cases not only bone, but bone-marrow, was found. Harvey believes that the process is one of ossification of previously formed connective tissue. R.

The Giant Cell of Tubercle.—There are two current theories as to the histogenesis of the giant cell so frequently found in tubercular lesions: (1) Origin from a single cell by multiplication of nuclei and enlargement of protoplasm; (2) formation by fusion of several cells. Laura Forster (*Journal of Pathology and Bacteriology*, October, 1907) puts forward a new theory. She holds that the so-called "giant cell" is not a cell at all, and has no function as a cell. It arises, she believes, from the coalescence of the cytoplasm of several epithelioid cells, the margins of which have merged and disappeared. As reasons for this view, she points out that the typical shape of the giant cell is really the result of shrinkage, and that with careful preparation the cell appears merely as a protoplasmic mass, filling the space between the epithelioid cells. Its form is moulded by the groin space. When considerable shrinkage has taken place the typical processes are seen, which, according to the author and others, are connections with the reticulum of the part. She believes she has observed a reticulum present in some giant cells. Mitotes figures were not observtd in the giant cells, nor was any evidence found of increase in the number of nuclei. The number of nuclei seemed to correspond with what would be found if a like space were occupied by epithelioid cells. She concludes, therefore, that the giant cell of chronic tuberculosis is a retrogressive metamorphosis, and one, if not the only, stage towards the process of caseation. R.

Phagocytic Action of the Alveolar Cells of the Lung.—Briscoe publishes (*Journal of Pathology and Bacteriology*, October, 1907) an account of a series of experiments undertaken to discover what cells undertake phagocytic duties in the lungs. His experiments were performed by introduction of foreign particles through a tube inserted into the trachea and carried down to the lung, the animal being killed a definite time after the inoculation. In different experiments, pigeons' blood corpuscles, staphylococci, and other organisms were employed, and the tests varied by the presence or absence of opsonins and minimum sera. The following are among the conclusions arrived at: (1) The mononucleal cells, whether containing pigmtnt granules or not, which are present in the alveoli, when of sufficient size, are powerful phagocytes. (2) Their phagocytic action depends on the presence of an opsonin. (3) With a mild injection, by the help of on opsonin and without the intervention of leucocytes, the alveola cells can free the lungs of the organisms. (4) If the injection is more virulent, but not fatal, the polymorphs give active assistance. (5) Phagocytosis by the alveolar cells is more rapid when the injected bodies have been treated with minimum serum than when untreated organisms are injected with a previously immunised animal. (6) Phagocytosis is more rapid when the animal injected has been previously immunised than when a normal animal is employed. (7) During the first hour and a half nearly all the phagocytosis is performed by the alveolar cells. (8) The bronchioles, not being lined with phagocytic cells or mucous glands, are at a disadvantage as compared with the alveoli during the early part of an infection spreading down the trachea. R.

Morbid Anatomy and Histology of Myelocythæmia.—Gulland and Goodall report (*Journal of Pathology and Bacteriology*, January, 1908) the results of their examination of seven cases of myelocythæmia. The following are the principal findings, classified under the various organs:—*Liver.*—The portal spaces and hepatic capillaries were invaded by leucocytes, myelocytes predominating. Hæmoblasts were numerous in three cases. Large phagocytes, ingesting red and white cells, were found. Pigment was present in every case. *Spleen.*—The Malpighian corpuscles were small. The pulp was packed with leucocytes; nucleated red cells were frequent; giant-cells were numerous in two cases; phagocytes injecting red cells were found. Pigment was present in every case. *Kidneys.*—Catarrhal changes were present in four cases; leucocytic infiltration was frequent; pigment was found in the epithelial cells in two cases. *Bone Marrow.*—In every case the bone marrow was myelocytic. *Blood.*—The total counts of leucocytes varied between 200,000 and 500,000. The differential percentages varied greatly, not only in the different cases, but in the same case at different times. Thus, in different cases, the polymorphs varied from 10 to 77 per cent., and the myelocytes from 2 to 65 per cent. In one case the polymorphs were found to vary from 7 to 31 per cent., and the myelocytes from 44 to 68 per cent. Nucleated red cells, and especially myaloblasts, were numerous. R.

MEDICAL NEWS IN BRIEF

Royal College of Surgeons of England.

At a meeting of the Council, held last Thursday, Mr. Henry Morris, President, in the chair, the Secretary reported the deaths of Mr. Reginald Harrison, Vice-President, and Sir Alfred Cooper, Vice-President. Votes of condolence were unanimously passed expressing the deep regret of the Council at the death of their distinguished colleagues, and their sincere sympathy with Mrs. Harrison, Lady Agnes Cooper, and their families in the loss which they have sustained.

Mr. David Ranken, of Durham University, and Mr. B. A. Lloyd, of Birmingham University, having passed the required examinations and conformed to the by-laws, were admitted members of the college. Mr. W. A. Maggs, dental surgeon to Guy's Hospital, was re-elected a member of the Board of Examiners in Dental Surgery, and Mr. Rickman J. Godlee was elected the representative of the college upon the council of University College, Bristol in the vacancy occasioned by the resignation of Mr. Thomas Bryant.

A letter was received from the University of Liverpool asking the Council to accept two summer sessions and the second winter's attendance at general hospital practice for the L.D.S.Eng., instead of two winter sessions as required by the present regulations. The letter was referred to the Board of Examiners in Dental Surgery to consider and report thereon.

The Admission of Women as Members.—The President stated that he had fixed July 1st as the date for closing the poll of Fellows and Members on the subject of admitting women to the diplomas of the College. With regard to the question the following notice is to be circulated to the Fellows and Members: "The Council, although they have decided that it is desirable to admit women to examination to the diploma of member, and although they have power to act upon this opinion, are anxious, in accordance with a resolution passed at a meeting of the Council on May 9th, 1907, to obtain the views of Fellows and Members on the matter. In regard to the corporate position of women, if the diplomas of the College be granted to them, the council have taken legal opinion, and are advised that while under the Medical Act of 1876, women can be admitted as members or as Fellows, no woman so admitted would thereby be entitled to take any part in the government, management, or proceedings of the college. (a) In your opinion, is it desirable that women should be admitted by examination as members of the College? (b) In your opinion, is it desirable that women, after admission to the Membership, should be admitted by examination as Fellows of the College?"

Dublin Sanitary Association.

The annual meeting of the Dublin Sanitary Association was held last week in the Theatre of Leinster House, Major D. C. Courtney in the chair. The Secretary (Dr. P. C. Kirkpatrick) read the annual report, which stated that there were 131 members on the books of the Association, being 3 more than last year. For some years past the chief work which had occupied the attention of the Council was to endeavour to put some check on the high rate of infant mortality that obtains in all large cities. In that respect Dublin is more favourably situated than many of the large manufacturing towns in England, but still the waste of infant life, which to a large extent is the result of preventible causes is one of the most serious blots on the sanitary administration of the city. They earnestly appealed for funds to push forward the work successfully. The Council was impressed with the necessity of the strictest control being exercised over the milk supply. The report went on to observe that since the State had adopted the principle of compulsory school attendance it was only right that it should protect children from disabilities arising from such attendance. Such protection could only be secured by systematic and efficient medical supervision. On the subject of private slaughter-houses, which formed a serious blot on the sanitary administration of the city, the report stated that since the City Abattoir was opened in 1882, a considerable amount of public money had been spent on it, and that expenditure had been made on the understanding that the Abattoir was to replace the private slaughter-houses. The Council believed that the matter merited the most careful consideration of the city authorities, and that while steps should be taken immediately to put the city in possession of a thoroughly efficient abbattoir, it was almost useless to embark in that expense unless steps were at the same time taken to ensure that when ready it would not only replace some, but all, of the private slaughter houses The report referred to the recent wakening up throughout the country to stay the ravages of tuberculosis.

Consumption in the Army.

The preliminary report of the War Office Committee on the treatment of soldiers invalided for tuberculosis has been issued. The Committee is of opinion that the practicable methods of treatment resolves itself into three alternatives as follows: (1) To continue the present method, viz., to discharge at once from the Army any man who is diagnosed as suffering from tubercle of the lung, to discharge him from hospital as soon as he is fit to travel, and afterwards to disown all responsibility for him; (2) to provide a special central military sanatorium for tuberculous patients, to which all soldiers suffering from the disease should be sent for treatment; and (3) to make use of existing civil sanatoria, in all parts of the country, by reserving in each a number of beds at the expense of the Army funds, and by transferring soldiers who are suspected of having the disease to the available institution nearest to their own homes. The last method (3) is the one recommended by the Committee. Under existing arrangements no provision whatever is made by regulation for soldiers invalided for tubercle. The cost of this proposal cannot be ascertained in detail until the sanatoria have been consulted, but a rough idea of the amount involved can be given. About 200 beds would, it is computed, require to be maintained. The cost of these, at 30s. a week, would be £15,600 per annum. It may therefore be said that the total cost of the scheme will not exceed £20,000.

Male Nurses.

An appeal for £2,000 is made by the Army and Navy Male Nurses' Co-operation, recently founded under the patronage of her Majesty the Queen. Once started, it is hoped that it will be self-supporting. The object in view is to afford the public the opportunity of engaging well-trained male nurses and sick attendants of assured good character. The men supplied by the Co-operation are retired non-commissioned officers and men of the nursing section of the Royal Army Medical Corps and members of the Sick Berth Staff of the Royal Navy. The funds are needed to defray the initial cost of providing and equipping a suitable office, to be available day and night, of advertisements, and of obtaining a small house, where the men can lodge when waiting to be despatched to their cases. This latter requirement is essential in the interests of the patients served and for securing prompt response to all applications. The public, by supporting the movement, will be giving employment to a deserving class of men, and without such an organisation as the present find it difficult to obtain employment in their profession after leaving the Army or Navy

Scholarships for Students of Midwifery.

We are asked by the Executive Committee of the London County Council to announce that six Scholarships of £25 each to Students in Midwifery will be awarded in July next to candidates who must furnish satisfactory evidence as to character, must be not less than 25, and not more than 40 years of age. Candidates must also be prepared to satisfy the Council as to their need for pecuniary assistance for the purpose of training as midwives, and to enter into a bond with sureties that they intend to practice as midwives for two years among the poor within the area of the Administrative County of London. They must be resident within the area of Council, and will be required to pass a qualifying examination on May 15th in writing from dictation and elementary arithmetic, the standard being substantially equivalent to that set out in the Board of Education Code of Regulations for Public Elementary Schools, 1907. Candidates will be supplied with forms and additional information on application to the Executive Officer, Education Offices, Victoria Embankment, W.C.

King Edward's Hospital Fund.

We are asked to state that hospitals in the County of London, or within nine miles of Charing Cross, desiring to participate in the grants made by this fund for the year 1908 must make application before the 25th inst. to the honorary secretaries, 7 Walbrook, E.C. Applications will also be considered from convalescent homes and sanatoria for consumption which are situated within the above boundaries or which, being situated outside, take a large proportion of patients from London.

It will be seen that the scope of the operations of the fund has been extended by the enlargement of the radius from seven to nine miles from Charing Cross, as well as by the admission to consideration of the claims of consumption sanatoria situated in the country in those cases in which it can be shown that a large number of London patients are treated.

Another X-ray Victim.

Mr. T. J. Oliver, the X-ray operator at Leeds General Infirmary, has had an arm so badly affected by dermatitis that amputation was found to be necessary. Mr. Oliver's health has broken down and the Infirmary Board have granted him a pension of £1 5s. per week.

Trinity College, Dublin.

The following candidates passed the Final Medica Examination—Part I., at Hilary term, 1908:—Phibbsl John L., Frederick A. Anderson, Desmond Drew, Wellesley R. Allen.

Dr. George F. Blacker, F.R.C.P., Physician to University College Hospital and the Great Northern Central Hospital, has been appointed a Director of the Clerical and Medical Life Assurance Society, in the place of Sir William H. Broadbent, M.D., Bart., deceased.

Owing to a serious outbreak of whooping-cough, it has been decided to close the elementary schools in Northenden for a period of three weeks. Already five or six fatal cases have been reported.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

DR. JAMES A. S.—Steel instruments should not be steamed with the object of sterilising them. They should be boiled in water containing an alkali. In practice a heaped-up tablespoonful of washing soda to the gallon of water is used. The soda should never be omitted. It should also be remembered that no soda is contained in the steam from soda and water.

DR. BRILL.—The letter of Dr. Schweiger has been addressed to the gentleman referred to.

MR. GREATREX.—We have made inquiries, and have found that the work is out of print. A new edition, however, is in preparation, and will, we understand, be issued about October next.

DR. C. H.—Our correspondent has undoubtedly been misinformed. The present holder of the title is the grandson of the distinguished surgeon, who died in 1893.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, MARCH 18TH.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m.: Mr. C. F. Rousselet: Exhibition of Mounted Specimens. Right Hon. Lord Avebury: On Seeds, with Special Reference to British Plants.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Mr. M. Greenwood: The Physiological and Pathological Effects which follow Exposure to Compressed Air. (Arris and Gale Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. R. H. J. Swan: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. H. Thursfield: Post-Basal Meningitis.

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Surgical In-patients (Mr. Stabb); Medical Out-patients (Dr. Horder); Gynæcological (Dr. Lockyer); Skin (Dr. Whitfield); Teeth (Mr. Baly); Operations (Mr. Stabb).

THURSDAY, MARCH 19TH.

ROYAL SOCIETY OF MEDICINE (DERMATOLOGICAL SECTION) (20, Hanover Square, W.).—5 p.m.: Clinical Cases will be shown by Dr. J. H. Sequeira and others.

CHILD STUDY SOCIETY, LONDON (Parkes Museum, Margaret Street, W.).—8 p.m.: Dr. F. C. Shrubsall: Anthropometry and Physical Development (illustrated by lantern slides).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. L. Guthrie: Precocious Development.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture-Demonstration:—Mr. H. Evans: Congenital Dislocation of the Hip-Joint.

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—2.30 p.m.: Medical In-patients (Dr. Morison).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Lecture:—Dr. M. Dockrell: On the Treatment of Skin Diseases.

HOSPITAL FOR SICK CHILDREN (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Poynton: Rheumatism in Children under Five Years.

FRIDAY, MARCH 20TH.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, Cavendish Square, W.).—5 p.m.: Dr. F. Langmead, Dr. P. Weber, Dr. C. Chapman, Dr. G. Carpenter, Dr. P. Parkinson, Mr. S. Stephenson, and others: Cases and Specimens.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (20, Hanover Square, W.).—8.30 p.m.: Mr. A. E. Shipley: The Relation of Entozoa to the Mucous Lining of the Alimentary Canal. Dr. W. T. Prout: (1) The Role of Filaria in the Production of Disease; (2) Note on an Unusual Cause of Dysenteric Diarrhœa in the Tropics; (3) exhibit of the Sword of a Sword Fish removed from a man who had been transfixed by it.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m.: Mr. M. Greenwood: The Physiological and Pathological Effects which follow Exposure to Compressed Air. (Arris and Gale Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. R. Lake: Clinique. (Ear.)

GREAT NORTHERN CENTRAL HOSPITAL (Holloway Road, N.).—3.30 p.m.: Lecture:—Dr. A. Morison: On Cardio-pulmonary Murmurs, their Diagnosis and Signification.

Appointments.

BRISCOE, J. CHARLTON, M.D.Lond., Assistant Physician to King's College Hospital.

CROSS, F. G., F.R.C.S.Eng., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Kingston District of the county of Surrey.

EAGER, RICHARD, M.B.Aberd., Senior Assistant Medical Officer at the Devon County Asylum, Exminster.

HUDSON, BERNARD, M.D.Cantab., M.R.C.P.Lond., Assistant Physician to the Royal Hospital for Diseases of the Chest, City Road, E.C.

JEWESBURY, REGINALD C., M.B.Oxon., M.R.C.P.Lond., Assistant Physician to Charing Cross Hospital.

MONTESOLE, M. HERSCHEL, L.R.C.P.Lond., M.R.C.S., Junior House Surgeon at the Western General Dispensary, Marylebone Road, N.W.

RIGGALL, ROBERT MARMADUKE, M.R.C.S., L.R.C.P., Second Assistant Medical Officer at the Devon County Asylum, Exminster.

SILVER, CLIFFORD MARKING, L.D.S.Eng., Dental Surgeon to the Exeter Dental Hospital.

WATKINS, JOHN G., L.R.C.P.Lond., M.R.C.S., District Medical Officer by the Taunton Board of Guardians.

Vacancies.

The Royal National Orthopædic Hospital, 234, Gt. Portland Street, W.—House Surgeon. Salary, £250 per annum. Applications to the Secretary.

Jaffray Branch of the General Hospital, Gravelly Hill, near Birmingham.—Resident Medical and Surgical Officer. Salary, £150 per annum, with board, residence, and washing. Applications to the House Governor, General Hospital, Birmingham.

Borough of Ipswich.—Assistant Medical Officer of Health. Salary, £150 per annum. Applications to Will. Bantoft, Town Clerk, Town Hall, Ipswich.

University of Manchester.—Senior Demonstrator in Physiology. Salary, £150 per annum. Applications to the Registrar.

Urban District of Finchley.—Medical Officer of Health. Salary, £300 per annum. Applications to E. H. Lister, Clerk to the Council, Council Offices. Church End, Finchley.

Devon County Asylum, Exminster.—Third Assistant Medical Officer. Salary, £140 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, Asylum, Exminster.

Kent County Council.—Medical Officer of Health. Salary, £800 per annum, with all travelling expenses. Applications to W. B. Prosser, Clerk of the Kent County Council, Sessions House, Maidstone.

Women's National Health Association (Carlow Branch).—Qualified Nurse. Salary, £70. Applications to Hon. Sec. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer for eight months. Salary, £20, washing allowance £2 10s, with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician for eight months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

Births.

BARENT.—On March 14th, at 65, Rodney Street, Liverpool, the wife of Frank H. Barent, M.D. Lond., F.R.C.S., of a daughter.

CLARK.—On March 13th, at 88, Chamberlayne Wood Road, Kensal-rise, Kathleen, the wife of Reginald Clark, M.R.C.S., L.R.C.P., of a son.

MAXWELL.—On Feb. 3rd, at Yung-chun, Fuhkien Province, China, the wife of J. Preston Maxwell, M.B., F.R.C.S., of a daughter.

MORTON PALMER.—On March 9th, at 13, Orchard Gardens, Teignmouth, S. Devon, the wife of F. W. Morton Palmer, M.A., M.B., B.C.Cantab., of a son.

OXLEY.—On March 10th, at Osborne Road, Buckhurst Hill, Essex, the wife of F. J. Oxley, M.R.C.S., L.R.C.P., of a son.

Marriages.

BRUCE-LOW—BERGEN.—On March 12th, at the Cathedral, at Singapore, Robert Bruce-Low, jun., M.R.C.S., L.R.C.P.Lond., of Kuching, Assistant Government Medical Officer to the State of Sarawak, youngest son of Robert Bruce-Low, Esq., M.D., Helmsley House, 92, Christchurch Road, Tulse Hill, London, to Eva Charlotte Louise, only daughter of Henry Bergen, of Balham.

Deaths.

MAYNARD.—On March 15th, at Erith, Kent, J. Martin Maynard M.R.C.P., M.R.C.S., J.P., aged 72 years.

GOOLDEN.—On March 11th, at 4, Clifton Place, London, W., of heart failure, Richard Edward Goolden, of Horton Grange, Maidenhead, eldest son of the late Richard Henry Goolden, M.D., F.R.C.P.

Pneumonia, Pleurisy, and Sequelae.

The administration of Angier's Emulsion during and after attacks of Pneumonia or Pleurisy is based upon sound, logical and scientific reasons. To combat the exhaustion attendant upon these diseases is the first thought in treatment. What more rational method of doing this than by supporting the patient with nutritious food, and the adminis-tration of a remedy that assures its perfect digestion and assimilation, and its conversion into the nutritional power that is Nature's own weapon against the ravages of infection of any character? Angier's Emulsion has this effect and more. Its sedative irritation-allaying influences upon inflammatory affections of the respiratory organs are simply unique. It relieves the pulmonary distress, the hacking cough, the difficult expectoration of Pneumonia and Pleurisy with a rapidity and completeness that are, at times, surprising. After the battle—when the disease has run its course—and the nervous system, the patient's nutrition and vitality are at the lowest ebb, try the continued use of Angier's Emulsion for a convincing proof of its effects as a tonic, and reconstructive of blood, tissue and vitality.

FREE SAMPLES TO THE MEDICAL PROFESSION.

ANGIER'S EMULSION

THE ANGIER CHEMICAL CO., Ltd., 32 Snow Hill, LONDON, E.C.

SCHERING'S MODERN THERAPEUTICS

EXODIN

Tasteless and Odourless Laxative, in Table form, Mild, but Sure and Safe.

SUBLAMIN

Non-irritant Sulphate of Mercuric Ethylendiamine Preparation for Hand Disinfection.

EMPYROFORM

Dry, almost Odourless Tar Preparation. No Local Irritation or Intoxication. Excellent in treatment of Eczema, Psoriasis, etc.

EUPHTHALMIN

Powerful Mydriatic: Excellent in Acute and Chronic Iritis. Far superior to all other Agents for Ophthalmoscopic Examinations.

BETA EUCAIN LACTATE

Local Anæsthetic par excellence. Soluble up to 20%. Toxic effects reduced to a minimum.

PIPERAZINE **PHENOCOLL** **CHLORALAMID** &c.

FOR SAMPLES AND LITERATURE APPLY TO

London, E.C.

T.H.H.

The "Lancet" on Cocoa.

Of the beverages in common use (Tea, Coffee & Cocoa), Cocoa is the best, because—

1. It is not a mere stimulant; it is also a true food.
2. Its stimulant value is similar to that of beef tea, and its nutritive value bears comparison with that of milk.

Of test cocoas bought in the open market, Van Houten's proved to be the best; because—

1. It is the most finely sub-divided, leaving no sediment in the cup.
2. It is the most soluble and perfectly miscible, consequently the most economical in use.
3. It is the most readily digested in the gastric juices.
4. It contains the maximum proportion of the proximate principles of food.

These facts, **elicited by unbiassed scientific investigation (vide "Lancet," Jan. 7th and Feb. 4th, 1905)** place Van Houten's Cocoa in the front rank of modern dietetic preparations.

It is quickly absorbed in the stomach, leaving no undigested irritant residue, and is therefore pre-eminently suitable for invalids.

VAN HOUTEN'S COCOA.

Active principle of the medulla of the supra-renal gland

I-1000

In 0·5 c.c., 5 c.c. and 10 c.c. containers

Physiologically standardised by accurate scientific methods. Reliable, uniform and stable, and free from irritant properties.

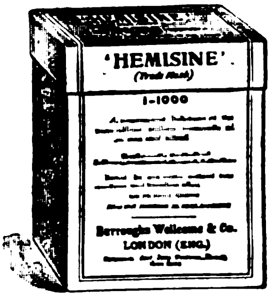
TRADE MARK 'VAPOROLE' BRAND 'HEMISINE'

In hermetically-sealed phials, each containing 0·5 c.c. of 1 in 1000 solution. *Sterile* and suitable for the preparation of convenient amounts of aseptic solution. Especially adapted for injection and local application.

Supplied to the Medical Profession, in boxes containing 1 dozen phials, at 2/6 per box

TRADE 'HEMISINE' MARK

In amber-coloured glass-stoppered bottles containing 5 c.c. or 10 c.c. of 1 in 1000 solution. Specially suitable for internal administration or for local application. Each carton contains a supply of 'Soloid' Sodium Chloride, 0.17 gm., for the preparation of Normal Saline Solution for use in diluting 'Hemisine.'



Reduced facsimile.

Supplied to the Medical Profession as follow: 5 c.c. 1/3; 10 c.c. 2/-

The

'Allenburys' Foods

Special Advantages:

1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.

2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.

3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.

4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.

5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.

6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

MILK FOOD No. 1. From Birth to 3 months.
MILK FOOD No. 2. From 3 to 6 months.
MALTED FOOD No. 3. From 6 months upwards.

A descriptive Pamphlet, giving Analyses, etc., and Samples of the Foods will be sent on request.

ALLEN & HANBURYS LTD.,

37, Lombard Street, London, E.C.

UNITED STATES—Niagara Falls, N.Y.
CANADA—Gerrard Street East, Toronto.
AUSTRALASIA—Bridge Street, Sydney.
SOUTH AFRICA—Castle St., Cape Town.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, MARCH 25, 1908. No. 13.

NOTES AND COMMENTS.

Nauheim in London.

SOME six months or so ago medical men were offended to see in the columns of the *Times* and other papers a series of blatant advertisements of an institute professing to give the "Nauheim Kur" in London, and very properly advised such patients as consulted them on the point to have nothing to do with the concern. It seems that the company, which had undoubtedly sunk a large amount of money in the enterprise, thought it possible to run with the hare and hunt with the hounds, that is to say, they did not fully realise the strength of medical sentiment on the question of patients with serious diseases being in the hands of lay persons for treatment. Disillusionment, however, on that point was brought home in the most practical way by medical opposition, and the refusal of the medical journals to take advertisements from the institute. We have good reason to believe that the proprietors have now repented of the error of their ways, and wish to run their business on ethical lines. They have given up advertising in the lay press, and three months ago engaged two medical men, Dr. Bain and Dr. Hill, to take charge of patients sent to them, and to prescribe and direct treatment in all cases. They assert their willingness for medical practitioners to supervise the treatment of their patients, if so desired, and, whenever possible by the circumstances of the case, they are prepared to refuse treatment to patients unless the family attendant is agreeable, or, at any rate, has had the opportunity of expressing his own views.

On Right Lines.

FROM a personal inspection of the institute, we can say that the arrangements and fitting up of the installations are very good. On the ground floor are baths and cubicles for men, and on the top floor similar appliances for women, whilst the two intermediate floors are occupied by separate gymnasia and exercise rooms for the two sexes. The baths and general system of treatment differ in some minor points from that carried out at Nauheim, but practically the same plan prevails at both, and medical men wishing their patients to undergo the treatment, have, therefore, a favourable opportunity of recommending them to undertake it in London, instead of after the fatiguing journey to Nauheim itself. The benedictions of others than ourselves have, before this, been passed on the new institute, and there are already cases under treatment sent by some of the leading hospital physicians. Its aim seems to us to be much the same as a hydropathic institution, namely, for a private company to conduct the business part, and to provide the regular staff, and for medical men, on their part, to undertake the direction of the treatment, and full responsibility for it. It is fair then to say that the ban previously, and very properly, placed on the institute should now be withdrawn, on the ground that the desire is to cater for a want in a legitimate and ethical way. We think it would certainly conduce to the establishment of confidence, if the proprietors had a board of highly-placed physicians to advise them on matters from time to time.

Indecent Advertisements.

QUITE the most objectionable type of quack advertiser is he who mingles with his ordinary trade, or makes his ordinary trade a cloak for, the purveying of sexual stimulants and similar filth. It is fair to say that there has been a great improvement in the lay Press of late years with regard to advertisements of this type, but there are still several journals which, under one disguise and another, publish announcements whose real character cannot be mistaken. With the extra vigilance of the police as to bills pasted up in urinals and similar delectable places, the gentry who live on this disgusting trade have considerably fewer opportunities of purveying their wares, and consequently fresh avenues for business have to be sought. The most offensive way which these dealers take to dispose of their "goods" is to send the descriptive pamphlets of them to recently-confined ladies, whose names and addresses are taken from the births column of the newspapers. The practice appears to be a very common one, and it is hardly possible to imagine a greater insult than for young mothers to be made the recipients of printed matter of this kind, especially when, as is usually the case, the covering envelopes are marked "Private." The suggestion in such cases is that the wife should conceal the receipt from the husband, and perhaps there is a certain fear of physical violence if the advertisements reached the husband direct.

How to Stop Them.

WE are therefore very glad to see the matter was taken up in the most practical manner by a medical man last week. A firm trading as the Cardinal Manufacturing Company, Wilson Street, Finsbury, having sent some of these indecent advertisements to his wife, who had given birth to a child a few days before, the doctor in question communicated with the police at Scotland Yard, and as a result of his action a summons was taken out under Section 4 of the Post Office Protection Act, 1884, which makes it an offence to send indecent matter through the post. The summons was heard at Bow Street, and it is perhaps hardly necessary to say that the company, which seems to be doing a large business, did not put forward any witnesses. A feeble attempt was made by the solicitor who defended to make out that the advertisements were not indecent because the words used were to be found in the dictionary, and because good-class firms advertised in their catalogues drugs like nux vomica, which have an aphrodisiac effect. This sort of stuff did not go down with the magistrate, who considered the offence proved, and to have been aggravated by the circumstances, and the full fine, £10, together with £5 5s. costs, was imposed. This case should therefore act as a precedent and an incentive. It is quite worth a man's while to give up an hour or two of his time to put a stop to this obnoxious practice, and if the trade of the Cardinal Manufacturing Company, or any other similar indecent firm, were broken up by such proceedings, we fancy it would not be much loss to anyone.

Compulsory Operations. The important question whether a workman drawing compensation under the new Act can be compelled to undergo a reasonably safe operation for the relief of the condition he is suffering from, came up again last week at the City of London Court. The question as regards Scotland was recently settled by a judge reducing the claimant's compensation to a shilling a week till the operation had been performed, but it has yet to be decided definitely in England. In the case under notice the workman had had an injury to the knee which had displaced the internal semilunar cartilage, and the plaintiff rather than undergo an operation for the relief of the condition preferred to continue indefinitely on half wages. Medical evidence on both sides was to the effect that the risk was practically confined to the risk of the anæsthetic, and that the result would almost certainly be a complete cure. Judge Rentoul, before whom the case was tried, held that in face of the evidence the workman, as a reasonable being, ought to submit to the operation. However, having regard to the importance of the point, His Honour would not take the responsibility of saying the man was bound to, or of ordering the stoppage of his compensation, until the matter had been submitted to the Court of Appeal. We think the learned judge's conclusion a sound one, and we hope the matter will now be definitely settled. There is a class of man who prefers to make the most of a disablement of this type till the employers can be induced to part with a lump sum in settlement. Then he undergoes the operation and starts on full wages again.

Hard Cases under the Act. Beneficent in the main as the Act is to the working classes, it operates with cruel injustice in some instances. Last week a case was reported from Manchester of a cycle fitter who has been lame since 1888 as the result of an accident to his knee, but who, owing to his skill and diligence, never had any difficulty in obtaining employment till the Act came into force. His masters at that time directed all their employees to undergo a medical examination on behalf of the insurance company which was to indemnify them, and the doctor's report was to the effect that if any further accident happened to the man the limb might have to be amputated. The insurance company thereupon refused the risk, and the man was compelled to leave his employment, and has not since been able to obtain work because of his defect. Once or twice, indeed, when he has been taken on by firms when they were busy, he has been dismissed when his lameness was noticed. It is pleasing to note that the man says that his warmest sympathisers are the medical men who have examined him; but, grateful as such sympathy may be, it is a poor substitute for board and lodging. We certainly may reckon ourselves among the sympathisers of such patients, but we do not see how their case is to be remedied by legislation or any other means.

LEADING ARTICLES.

THE LECTURE SYSTEM IN MEDICAL EDUCATION.

The art of teaching, like other human institutions, is governed by processes of evolution which will doubtless, sooner or later, lead to the best system attainable under existing conditions. So far as medical education is concerned, the whole field is constantly undergoing such rapid extension and change that frequent revision of methods is especially desirable. One of the old-standing questions that has vexed the minds of teachers for generations past is the desirability or otherwise of compulsory lectures. Long ago, when fewer books were available, it became necessary for the teacher to deliver his message orally. Now it is difficult to realise the experience which induced the further disciplinary step of rendering attendance upon such lectures compulsory. Human nature is much the same all the world over, and among a number of medical students a certain number will always shirk the burden of systematic study wherever possible. But the career of the student has changed of recent years in a manner hardly less remarkable than the revolution which has overtaken many principles of medical and surgical practice. The standards of examination are greatly raised, and it is impossible nowadays for the ignorant and careless student to attain the goal of medical qualification. Under modern conditions, then, it seems clear that some at least of the former arguments in favour of compulsory lectures have disappeared, while in other directions a new order of things has arisen. So far as the lecturer was concerned, it was natural enough that, after the first effort of preparing up his course of systematic lectures, he should be content to deliver them session after session in stereotyped form, bringing them up to date from time to time in the light of fresh discoveries. In some instances the lecturer publishes his lectures in book form, while in the majority of schools where stereotyped lectures of the kind were delivered it is possible to obtain note-books covering the whole of the ground. Under these circumstances the question arises with redoubled force as to whether the student is not wasting his time in attending lectures, the sub- of which can be more readily acquired from other sources. Possibly the true reading of the problem is, that while the diligent student might dispense with lectures readily enough, on the other hand, his less energetic or dull companion might suffer greatly if deprived of the daily modicum of instruction. Then, again, there are positive advantages in the system of oral delivery whereby the individualism of the lecturer is impressed in many ways. Indeed, perhaps the best test of the competency of any given teacher is the power of filling his classrooms. That test is applied in foreign universities where classes are not, as a rule, compulsory. For that matter, it may be taken for granted that some lecturers would secure a good attendance whether obligatory or otherwise. In one famous Scottish university it was the custom of more than one of the professors to call the roll on certain fixed days, but their class-rooms were always full, regardless of the fact that names would or would not be registered on any given occasion. But all lecturers are not competent any more than all medical students are capable and studious. It is not impossible that the system of compulsory lectures has outgrown its original sphere of usefulness. At any rate, there seems to be some indication from various professional quarters that it would be well to revise the situation with regard to a time-honoured method which has proved a potent weapon in the hands of past generations of medical teachers.

CURRENT TOPICS.

The Physiological Age for Smoking.

AT what age can smoking be countenanced by the physiologist and the physician? Like most apparently simple medical questions, that modest-looking query takes a good deal of answering. One thing may be said off-hand without a moment's hesitation, namely, that juvenile smoking is a bad thing from every point of view. Then, again, excessive smoking is injurious at any age, but that is implied in the condition of excess. A great deal depends on the individual himself with regard to the effects of tobacco upon his constitution. If he be vigorous, well-fed, and under good conditions of general environment, he can withstand quantities of tobacco poison that would wreck a weaker vessel. As regards the latter end of life, it is interesting to note how many veterans gradually curtail or altogether discontinue the habit of smoking. That is most likely an unconscious surrender to hidden physiological promptings, which show that the pipe or cigar is no longer smoothly tolerated by the nervous system as in days of yore. Not long ago a speaker at a Northern university conference moved that physiology be included amongst the list of subjects for a degree in Arts. One of his arguments was that divinity students thus educated would become sounder advocates of such social problems as that of temperance. Probably, he added, they would acquire much light on the heinous practice of smoking. The heart of that assembly of learned men was sorely vexed by this frontal attack, and so great was the subsequent confusion that the speaker hurriedly qualified his statement by the assurance that he meant smoking by boys under fourteen. Possibly a further conference of Scottish universities might settle the exact age at which a man might be permitted to begin smoking, and the hardly less important point as to when he should leave off that altogether unnecessary indulgence.

Soothing Syrups for Children.

AMONGST the causes of excessive infantile mortality may be reckoned the various soothing syrups and carminatives sold under various names. In nine cases out of ten they contain some preparation of opium, and in the tenth some deadly drug, such as acetanilide or chloral. The number of deaths of infants due to the use of these nostrums must be enormous, although there is, of course, no means of securing precise information upon the point. While newspapers share in the profits of this nefarious traffic it seems hopeless to anticipate any serious lessening of the evil. For all that, the resources of modern civilisation are by no means exhausted. The police have the power in many instances to institute prosecutions. One way in which they might do good is by prosecuting in all cases where a scheduled poison is contained in the preparation sold, but where the word "poison" is not attached to the label. Many mothers would hesitate before giving a baby an openly declared poison. The other method whereby the police might deal a deadly blow upon the patent medicine trade is by proceeding against those who make obviously impossible promises to cure various maladies. The police, however, are slow to take action in such matters. Indeed, it seems that the higher authorities will have to be carefully educated as to the meaning and the extent of the evil before any efficient action will be taken by the administrative arm of the State. The general education of the public may probably be best attained by the publicity attached to the proceedings of a much-needed Royal Commission upon secret remedies and cures of all kinds.

The King Edward's Fund and Hospital Out-patients.

THE annual meeting of the President and General Council of the King Edward's Hospital Fund was held on Friday last at Marlborough House. The Prince of Wales, in moving the adoption of the report, made an important announcement with regard to the out-patient system as follows:—"Since our Council meeting in December, acting on the advice of the Executive Committee, and in acordance with the powers given under the Act, I have decided to appoint a committee to inquire into the system prevailing in the London voluntary hospitals regarding the admission of out-patients. It is to be hoped that the labour involved in the holding of such an inquiry may perhaps to some extent be lightened by the results of the work of the Royal Commission on Poor Laws." The need of some such investigation will be universally endorsed by general practitioners, upon whose shoulders the brunt of hospital competition falls. If the Fund be judicial enough to lay bare the facts of the case, and sufficiently courageous to enforce an adequate remedy, they will most assuredly earn the gratitude of the medical profession. It seems hardly likely, however, that the King Edward's Fund will ever attain the goal of absolute justice under its present irresponsible constitution. The day of pure autocracy is dead, and no non-representative body with great public duties to perform can hope to retain a hold upon the confidence of the people. One result of this autocratic policy is the destruction of the small hospitals which are being slowly crushed out of existence by the Metropolitan Sunday and King Edward's Funds, regardless of their past or present careers of usefulness, or of the former support which has been diverted to the Funds. With every admiration for the spirit which has animated the creation of so magnificent a charitable agency as the King Edward's Fund, we fear it will never attain the full measure of achievement to which it is entitled until its Council is elected upon a broad representative basis.

Cerebro-Spinal Fever in Dublin.

SOME anxiety has been occasioned in Dublin by the news that there has been recently a marked increase in the number of cases of cerebro-spinal fever in the city. It is just twelve months since the first cases occurred, and though a considerable number were recorded during the summer months, during the winter season the disease dwindled down. The city, however, has never got entirely free from it, and deaths from cerebro-spinal fever have been registered at frequent intervals. It is, therefore, natural that some uneasiness should prevail lest the recent increase in the number of cases should be the first sign of a serious outbreak, such as that from which Belfast suffered last year. Dublin has barely escaped so far, and the danger of an epidemic has not passed. There seems, too, to be a policy of silence on the part of the health authorities, which does not tend to allay uneasiness. They are so much in the habit of calling "Peace" when there is no peace, that when they say "Peace," one at once suspects something wrong. It would appear, however, that up to the present the number of cases of cerebro-spinal fever is not such as should cause undue alarm, and we hope that Dublin may soon be free of the disease.

Proposed Legislation for Dublin.

We cannot pretend to regret that the Dublin (Various Powers) Bill, on which we commented some weeks ago (Medical Press and Circular, February 12, 1908), is dead. Before proceeding further in Parliament it was necessary to hold a plebiscite for or against the Bill, and, by a large majority, the burgesses of the city have scouted it. As we pointed out, the promoters of the Bill, in deference to the opposition of interested parties, notably dairymen and butchers, gutted the Bill of its public health clauses. In spite of this it came before the public with the many-columned blessings of certain medical men, who, apparently, had not noticed the omission of the clauses which might have merited their praise. We do not claim that the burgesses of Dublin rejected the Bill promoted by their elected representatives from any interest in the public health. There is no reason to suppose that the opinion of the public in Dublin is any more instructed than the opinion of those who are primarily responsible for the present disastrous conditions. The Bill was probably rejected purely from motives of economy. It is of interest, nevertheless, and it is of good omen, to find the citizens exercising their power to control the vagaries of the Corporation. It impresses on the members of the latter some sense of their responsibility, and it suggests the possibility of the citizens being awakened to a sense of their own duty, as well as of their power.

The Danger of the Hot-water Bottle.

In certain depressed states of the circulation the hot-water bottle is a valuable aid to the therapeutics of the sick room. That there are various risks attached to the use of this homely appliance should be known to every good nurse. The chief dangers arise when sensibility is impaired in any way or when the circulation is sluggish and the vitality of tissues impaired, as in the case of spinal palsies. In a recent case investigated by a coroner's jury in Manchester death was indirectly due to burns caused by a hot-water bottle. The deceased had suffered from diabetes and locomotor ataxy, and underwent an amputation of one of his legs for gangrene. The nurse noticed some burns on the remaining foot, but failed to call the attention of the medical attendant to them. She dressed the wounds with boracic ointment, and they all healed with the exception of one on the heel. The jury returned a verdict of death from natural causes, and added the extraordinary opinion that "the nurse should have told the doctor of the burns at once, and placed the responsibility upon him." This suggestion of making a scapegoat of the medical attendant for the carelessness and neglect of an obvious duty by a nurse is somewhat curious. We venture to believe there are few modern-trained nurses who would fail to report wounds or inflammations in a patient suffering from locomotor ataxy.

Death under Chloroform.

An inquest held recently in the country revealed a death under somewhat unusual circumstances. A tradesman of the town, having fractured his fibula, an operation was subsequently found necessary, and this was undertaken at the General Hospital. The operation was performed, and the patient appeared to be doing well, when he was left with a sister and a nurse by the house surgeon. A few minutes later the latter was called back hurriedly by the nurse, and found the patient dead. A post-mortem examination showed that there had been vomiting of solid food, some of which had regurgitated into the windpipe and caused suffocation. The jury found that the cause of death was heart failure, and that the chloroform was properly administered. It certainly seems from the foregoing account of the case, which we take from the *Western Daily Press* of March 19th, that the patient should not have been left by the administrator when recovering from anæsthesia. Presumably there was no time to prepare the patient, whose stomach was full at the time of the accident. Under such circumstances the administrator should obviously be more than ever on his guard against the risks of post-anæsthetic vomiting. This case shows the necessity of detailed reports of every fatal case under an anæsthetic. If this death were returned under the heading of chloroform, it would be, of course, fallacious, as vomiting might have caused a similar fatal result in the case of any other drug.

The British Medical Association Referendum.

A correspondent has drawn attention to the apathy of the 20,673 members of the British Medical Association, inasmuch as only 1,978 took the trouble to vote on the highly important matters submitted to them by Referendum. That aspect of the voting is not without its significance, as showing the difficulty of arousing medical men to look after their own affairs. Another aspect of the matter of hardly less significance is the revolt of the Association against the government of the Council. The Council considered the resolution passed by the Special Representative Meeting held in London in May, 1907, did not properly represent the wishes of the Association. The Council put various principles to the Referendum, with the result that the decisions of the representatives have been endorsed by two to one of those who voted in the United Kingdom. Medical men are so accustomed to have their institutions governed by councils that it is refreshing to see a great Association insisting upon having its own say on matters vital to its independence and self-government.

Infantile Mortality.

The excessive death-rate amongst infants has at length awakened the conscience of the world at large, and it is to be hoped that with the progress of scientific medical knowledge this waste of human life may be prevented so far as it is preventible. The International Congress, recently held at Brussels, has re-awakened public attention to the facts of the case. The death-rate per 1,000 in various European countries among children below one year of age is stated to be approximately as follows:—Norway 79, Sweden 93, Denmark 112, England 132, France 137, Belgium 155, Italy 172, Germany 204. In Japan the mortality is 152 per thousand. Startling as these figures are, they become dwarfed by the returns from some parts of Russia. According to the last available Russian statistics, the death-rate among children in the Chernigoff, Kharkoff, and Poltava Governments is 217; in the Smolensk, Tamboff, and Vilna Governments 310; and in the Nijni-Vovogorod, Perm, and Viatka Governments, 440. The only diminution shown is in the frontier provinces. Esthonia and Courland have a death-rate of 163, and Finland of 127. A Reuter's telegram states that the annual mortality in European Russia among children under twelve months reaches the enormous figure of over 1,200,000. There are many factors at work in this deplorable waste of human life, but none of them should be beyond the ultimate understanding of scientific medicine.

Commercial Logic,

Clearly, the proper enforcement of the Dangerous Trades Regulations of the Factory Acts is highly desirable in the interests of the working classes. From an economic point of view it acts as a kind of insurance premium, and in the long run saves the pocket of the ratepayer, who has to support the disabled victims of trade diseases. That there are many offences on the part of employers is doubtless true, but for all that the lot of the labourer is now immensely lightened. In a recent prosecution of the British Rubber Manufacturing Company for breaches of the Factory Act, it was proved by the Home Office Inspector, Dr. Legg, that in one process the worker was exposed to the fumes of naphtha, and in another to those of bisulphide of carbon. The manager of the works said that the work required by the Inspector had not been hitherto carried out, owing to technical difficulties. As a matter of fact, he stated that only two girls were engaged in the work where the fumes were. The fallacy of that line was ruthlessly exposed by the magistrate, who pointed out that two girls had just as much right to be protected as 2,000. This illustration of commercial logic throws an interesting sidelight upon the intellectual methods of employers when put on their defence for injuries caused to workpeople by the neglect of statutory obligations. On similar lines the Government of Hayti might now plead that they had murdered only five citizens without trial, and therefore nothing more need be said about the matter.

PERSONAL.

On Friday last, the 20th inst., the Queen, accompanied by her sister the Dowager Empress of Russia and Princess Victoria, paid an unexpected visit to the Royal Military Hospital at Millbank.

Later the royal party visited the Army Medical College, in the pathological laboratory of which Sir Frederick Treves presented Colonel Bruce, the discoverer of the organism of Malta fever.

It is announced that H.M. the Queen has given permission for the North-Eastern Hospital for Children, Hackney Road, to be known in future as "The Queen's Hospital for Children." A special meeting of the governors of the institution will be held on April 2nd, at 4 p.m., to receive this information formally.

Dr. D. T. Rocyn-Jones has been appointed Medical Officer of Health for Monmouthshire.

Surgeon-General John D. Edge, C.B., of the Army Medical Service, has been placed on the retired list.

Dr. C. Theodore Williams, M.V.O., is to preside at the annual general meeting of the Medical Graduates' College and Polyclinic on Friday next, at 22 Chenies Street, W.C.

Dr. Arthur Mechan has been elected first President of the newly-formed Western Medical Society at Glasgow, and Drs. William Snodgrass and Gibson Graham vice-presidents.

Her Excellency the Countess of Aberdeen opened the Tuberculosis Exhibition at the Guildhall, Londonderry, on Wednesday last, in the presence of a large assembly.

Prof. G. Sims Woodhead inaugurated the Northern Counties' Branch of the Incorporated Institute of Hygiene at the Armstrong College, Newcastle, on Monday evening last.

Principal Donald MacAlister, President of the General Medical Council, has been appointed representative of the University of Glasgow on that body in the stead of the late Sir Thomas McCall Anderson.

Mr. Rickman J. Godlee has been elected representative of the Royal College of Surgeons of England on the Council of University College, Bristol, in the room of Mr. Thomas Bryant, resigned.

We are much pleased to announce that the First Lord of the Treasury has granted a Civil List Pension of £120 to Dr. Hall-Edwards in recognition of his services to medical science and the misfortune his pertinacity has brought upon him.

Sir Henry Swanzy, President of the Royal College of Physicians of Ireland, has been selected as President of the Section of Ophthalmology at the forthcoming annual meeting of the British Medical Associaton, and Dr. James Craig, as Vice-President of the Medical Section.

Dr. R. H. Scanes Spicer, on retiring from the position of Surgeon for Diseases of the Throat to St. Mary's Hospital, which post he has filled with distinction during the last twenty years, has been unanimously elected Honorary Consulting Surgeon for Diseases of the Throat to that institution.

Colonel J. Lane Notter, R.A.M.C., will take the chair at a provincial sessional meeting of the Royal Sanitary Institute at the Town Hall, Hull, on Saturday, April 4th. Dr. Wright Mason will open a discussion on "Diphtheria in Elementary Schools and its Prevention."

Sir Henry Littlejohn last week sent in his resignation of the post of Medical Officer of Health for Edinburgh, after nearly fifty years' service. Sir Henry is in his eightieth year, and all who have had the pleasure of his acquaintance will ungrudgingly hope for him the same vigorous health in his well-deserved retirement that he has possessed for so many years.

Dr. J. F. Dwyer, of Beaufort, was, on March 14th, appointed Principal Medical Officer of the Beaufort district under the Workmen's Doctors Fund Committee, at a salary of £500 a year. There were 55 applicants.

A CLINICAL LECTURE

ON

THE VALUE OF LABORATORY METHODS IN THE DIAGNOSIS OF TYPHOID FEVER.

By PROFESSOR LEON BLUM, M.D.,

Chief of the Laboratory of the Medical Clinique at the Medical School of Strasburg.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

EASY enough to diagnose in typical well-marked cases, it is quite otherwise when we are dealing with typhoid fever in which one, or several, or most of the characteristic signs are wanting. In many of these cases clinical observation alone may leave us in doubt even after the disease has run its complete course. On the one hand, we may mistake for enteric fever a disease which happens to present one or several of its symptoms, and which thus becomes impossible to distinguish therefrom. We are specially liable to be misled by the very signs to which we are accustomed to attach most importance—such, for instance, as a spotty, rose-coloured eruption, the ulcerated typhoid throat, etc. It may be objected that such cases are of their nature exceptional, and, though this may be conceded, they are nevertheless frequent enough to be interesting. On the other hand, the absence of certain symptoms to which we look to suggest typhoid fever may leave us in doubt or lead us astray. It is unnecessary to insist on the possibly grave consequences of error in either direction.

Modern bacteriological research, which has achieved more in respect of typhoid fever than of any other disease, has materially altered the aspect of things. We may indeed ask whether it has not now become possible to establish our diagnosis with certainty by basing it on objective signs free from all suspicion of subjective influences. Then, too, several other accessory methods of investigation have now become part of the routine clinical investigation, which, though less important, have the advantage of being easy of execution.

In future the term typhoid fever ought to be restricted to diseases demonstrated to be due to infection by Eberth's bacillus, cases in which it is absent being eliminated. In this way we may ultimately succeed in differentiating the numerous diseases commonly described *en bloc* as cases of typhoid fever, though due to different micro-organisms. The question arises whether traditional clinical methods will have to abdicate before these measures, or whether the latter should only be subservient and accessory to clinical diagnosis.

Daily practice provides an immediate reply to this question. Our conclusions are based on the observation of cases of typhoid fever treated at the Strasburg Medical Clinique, the para-typhoid cases having been intentionally put aside, although most of our conclusions apply as well to these as to typhoid fever proper. I propose to discuss procedures which have either enabled us to confirm the diagnosis or else to reject it, so that I shall not deal with the methods *per se*, but only with their diagnostic and practical value.

The bacteriological methods employed by us comprise the search for bacilli in the organism or the excreta of the patient, and the specific reactions that make their appearance in the organism under the influence of typhoid infection—agglutination and the bactericidal power of the serum. To these measures we may add the diazo-reaction and the leucocyte count.

Of all the clinical and bacteriological methods, the most important is unquestionably the search for the bacillus in the blood. Its presence is an irrefutable proof of the nature of the infection, whatever course the disease may run. This has never once failed us, and we know of no fact in opposition thereto.

In view of the absolute value attaching to the discovery of the bacillus in the blood, the examination must be conducted under conditions so strict that every possible source of error shall have been discarded. Our conclusions, therefore, are based exclusively on blood withdrawn under antiseptic precautions from a vein, and collected in duly sterilised recipients. The search for the bacillus is merely a matter of bacteriological technique. We know for certain that the bacillus is always, or almost always, present at the onset of the infection. The proportion varies according to the procedure employed from 80 to 100 per cent. The procedure adopted by us has been that of Kayser-Conradi, which is based on the property possessed by bile of favouring almost exclusively the multiplication of the typhoid bacillus. It entails very small quantities of culture medium, 5 c.c., which is inoculated with 2 or 3 c.c. of blood, so that it can easily be carried or sent by post.

The results obtained have been scheduled according to the gravity of the infection and the period at which the examination was made. Of 36 typhoid patients examined during the first week, hæmoculture was practised in 32. The bacillus was present in every instance of grave infection, in three-quarters of the medium cases, and in half of the mild cases. At a later period blood inoculation gave a positive result in 81 per cent. of the grave cases, while in the average and mild cases a negative result became more and more frequent the later the examination after the onset of the disease. This diminution was specially marked in respect of the mild cases in which, after the second week, the bacillus could only be discovered in about 6 per cent., and at a still later period it was uniformly negative.

The proportion of positive results obtained by us, especially during the first week, differs somewhat from that obtained by others, but this is not the fault of the method, but is to be explained by the fact that our statistics comprise a larger number of cases than all the others put together, so far, and this particularly in respect of average and mild cases, and it is precisely in these cases that the results have most influence on the statistics. In slight cases of the disease, which run a very rapid course, sero-diagnosis alone will enable us to recognise their nature.

It may be stated, therefore, that the chances of our finding the bacillus are greater the more pronounced the gravity of the case and the nearer to the onset the examination is made. Still, even under the most favourable conditions, it will not invariably be found when the examinations bear on a sufficiently large number of patients and extends to all forms of the disease.

Sero-diagnosis is one of the best-known bacteriological methods of research. It is much simpler than blood cultures, it only requires a few drops of blood, and can be carried out in a short time away from any laboratory. It possesses considerable diagnostic importance, enough in most instances for all practical purposes. Still, it is not absolute, and, as with every other symptom, its results must be accepted with reserve.

From a numerical point of view, our figures show that the result was negative in 50 per cent. of the cases during the first week, so that at this stage it is obviously inferior to hæmoculture in respect of grave and average cases, while in slight cases, on the contrary, we are more likely to recognise the disease by sero-diagnosis. At later stages the two procedures are of about equal value in respect of grave cases, while in average and slight cases agglutination has much the advantage of the other method.

In addition to being absent in half the cases at the onset, agglutination may fail in some instances for a long time, even until convalescence. We have witnessed a certain number of such cases, but we have never found bacilli in the blood in cases where the sero-reaction proved negative at all stages of the disease.

This is, indeed, a specific reaction, but its specificalness is not absolute. The agglutinating power does not depend upon only the particular organism, but extends to others of the same family. For instance, the serum of a typhoid patient may agglutinate not only the typhoid bacillus, but also its neighbour, the para-typhoid bacillus, and *vice versâ*. This lack of specificalness is of little practical importance, since both diseases are infectious, and the treatment of both is purely symptomatic.

But there is another aspect of the agglutination phenomenon which deserves attention—viz., that although agglutination indicates typhoid infection, it does not justify the conclusion that the subject is actually under its empire, for, as we know, this may persist for months, and even years, after an attack. I will relate two instances which show the importance of this fact.

A young man was seized with abdominal pain, without any special localisation. He walked to hospital, where he related that he had had no previous illness. On examination, the belly was rather more swollen on the right than the left side, with some muscular resistance, but not enough to prevent free palpation of the iliac fossa. Temperature, 99.5° F.; pulse, 100; leucocytes, 11,000, with pronounced polynucleosis; diazo-reaction negative. The temperature went up next day to 104° F.; belly wall soft; leucocytes, 13,300. In the evening some blood was taken for examination. Next morning the general state was decidedly unsatisfactory, with marked gurgling in the right iliac fossa, but no tumefaction in that situation. It was decided to operate, and we found a gangrenous appendix; yet sero-diagnosis had given a frankly positive reaction at 1—100. At the operation there were no traces of typhoid lesions, nor was the bacillus found in the stools. This patient's mother had been under our care in the previous year with appendicitis, and the diagnosis between it and typhoid remained uncertain for some time. She was 53 years of age, and had had typhoid fever when 18, followed seven years later by hepatic colic with jaundice. For twelve days before admission she had suffered from great pain in the right side of the abdomen, with liquid stools and vomiting. There was marked thickening in the right iliac fossa, with muscular resistance and tenderness. We diagnosed appendicitis; the temperature was about 103° F.; no diazo-reaction, but the urine contained a trace of albumin; sero-diagnosis gave a positive result, 1—50 macroscopically, and 1—100 microscopically. The temperature chart of the subsequent course very closely resembled that of typhoid fever. Throughout, the leucocytosis remained between 15,000 and 19,000, with marked polynucleosis. The bacteriological examination of the blood, fæcal matter, and urine, gave negative results. It remained a moot question whether the case was one of appendicitis in a former typhoid patient, or of typhoid fever with appendicitis.

These two cases suffice to exemplify the hesitation with which the results of sero-diagnosis must be accepted in doubtful cases.

We may formulate the following conclusions with regard to sero-diagnosis. The agglutination test, though the one to be preferred in practice, must always be accepted with caution. A negative result does not eliminate the possibility of its being a case of typhoid infection, especially when made early in the case, when the proportion of negative results is one in two. If we get a positive reaction, we are not justified in affirming forthwith the existence of actual typhoid infection. Doubtless it is a symptom of great value, but it requires to be scrutinised, like every other symptom, and it may thus serve to complete or diminish the sheaf of evidence which in the aggregate establishes a diagnosis. It is especially in doubtful, irregular cases that caution is required.

The research of the bacillus in the fæces has comparatively little diagnostic value, compared with blood culture and sero-diagnosis. Apart from the difficulties inherent to the search, the presence of so many other bacilli is very apt to lead to confusion. Nevertheless, we had recourse to repeated examination of the fæces and urine whenever the blood cultures proved negative in presence of clinical symptoms clearly pointing to typhoid infection. In three cases the discovery of the bacillus in the fæces settled the diagnosis, which was confirmed by the subsequent course. On the other hand, in doubtful cases running an irregular course, the presence of typhoid bacilli in the fæces would not constitute a decisive argument, and might even lead us astray.

In spite of repeated examinations for the bacillus in the blood and excrement, and the sero-diagnosis, there were several cases in which clinical observation led us to conclude in favour of typhoid fever. These were six in all. In four the absence of post-mortem examination or other certain indication left the diagnosis open. The bactericidal power was, unfortunately, not resorted to except in two instances, in which it confirmed the clinical diagnosis of typhoid. In these patients all the other methods of investigation proved negative, though carried out repeatedly at different stages of the disease. The bactericidal power of the serum appears, therefore, to be of great importance in cases of this kind, but in others the difficulty and the tediousness of the method render it impracticable in general practice.

Ehrlich's diazo-reaction did not appear to be of much assistance in our observations, and this for two reasons:—In mild and medium cases, especially in the former, in which it might have proved useful, it often failed, so that we are unable to endorse the view that the absence on repeated occasions of the diazo-reaction in the course of a febrile disease negatives the presumption of typhoid fever. Conversely its existence in other diseases than typhoid, such as tuberculosis, deprives it of any value as a means of differential diagnosis.

Although its absence in a grave infection does not plead in favour of typhoid fever, its existence only amounts to a sign which may prove useful along with others; but it requires to be confirmed by more conclusive symptoms. It is rather as an indication suggestive of a possible diagnosis that it alone possesses any value.

We attach much more importance to the leucocyte count and to the leucocytic formula. Typhoid fever belongs to the group of infective diseases which are accompanied by a reduction in the number of leucocytes. Yet during the first few days leucopenia is far from constant. Of 100 cases selected at hazard, Dr. Arnheim found 59 in which the leucocytes were below 5,000, 35 with a normal proportion, and 6 with an increase of over 9,000. Here, again, the same rule applies—the absence of leucopenia does not enable us to discard the possibility of typhoid, since it may be due to several causes. Early in the disease there may be polynuclear hyperleucocytosis, which is often present at this stage. In other instances some complication may explain the absence of any diminution of leucocytes, either in consequence of some pre-existing malady such as tuberculosis, or some secondary infection. Nevertheless, if we discard these two causes, there remains a certain proportion of unquestionably typhoid cases in which there is marked increase of leucocytes without any discoverable complication to explain the fact.

The diminution of leucocytes only possesses importance in doubtful or irregular cases, in which we have to decide the question for or against typhoid infection. Its absence in no wise justifies us in rejecting that contingency.

Then, too, we must remember that the leucocytes are diminished in other conditions, such as septicæmia and granulia, which are easily mistaken for typhoid. The initial polynucleosis is followed by progressive diminution of the number of polynuclear leucocytes, which may fall below that of the mononuclears. A reduction of leucocytes with mononucleosis constitutes the typical hæmatological sign of typhoid fever, and, judging from our experience, is a sign of very great importance.

Other febrile maladies, it is true, present a very similar leucocytic formula—measles, Malta fever, and possibly non-typhoid septicæmia, complicated with grave or pernicious anæmia. We have also met with it in two instances of coli-bacillosis. Still, it is, as a rule, fairly easy to distinguish these cases from typhoid by the other methods at our disposal.

The leucocytic formula has also proved of considerable assistance in cases where, hæmoculture having failed, we had to decide between relapse of typhoid fever or tuberculosis following typhoid.

Conclusions.—Hæmoculture is the procedure of election, the only one which, in the present state of our knowledge, can be regarded as absolutely conclusive of typhoid infection. At the onset it is, moreover, the one that gives the largest proportion of positive results.

Sero-reaction in doubtful cases always calls for careful examination, and is a sign of great value, but is not absolutely decisive. The same remark applies to the discovery of the bacillus in the fæces.

The diazo-reaction appears to be useful only in so far that its presence may suggest the possibility of typhoid fever.

The leucocyte count, in presence of a reduction in the total number, affords a valuable sign in favour of typhoid fever. Associated with mononucleosis, it may have a decisive value, and is of great assistance in differentiating relapses of typhoid fever from secondary complications.

The failure of these methods, or of one, or several, or even of all, does not enable us to discard for good all possibility of typhoid infection, even when they are practised at various stages.

Lastly, when careful clinical observation pleads in favour of typhoid fever, the negative results of laboratory methods are not *per se* a reason for discarding the diagnosis of typhoid. In cases of this kind, which are assuredly very rare, the examination of the bactericidal power of the serum will sometimes enable us to confirm the accuracy of the clinical diagnosis.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Edred M. Corner, M.Ch. Cantab, F.R.C S. Eng., Surgeon to Out-Patients, St. Thomas' Hospital, and to the Hospital for Sick Children. Subject: "Sub-Acute Infective Epiphysitis, with Illustrative Cases." A Post-Graduate Lecture delivered at the Hospital for Sick Children.*

ORIGINAL PAPERS.

THE RELATION OF PATHOLOGY TO MECHANICS AND CHEMISTRY.

By W. R. MACDERMOTT, M.B., T.C.D.,

Medical Officer, Poyntzpass District.

M. POINCARE, a mathematician and statesman, in his book, "Science and Hypothesis," tells us that the ephemeral nature of scientific theories takes by surprise the man of the world. However potent their hold on mind may be for a time, he sees them given up one after another; he sees ruin piled on ruin; he predicts that the theories in fashion to-day will vanish to-morrow, and he concludes that they are vanities. He calls this the bankruptcy of science.

Is medical science bankrupt because its theories answer this description? No, because it keeps and has to keep to experiment; all its theories begin in empiricism, and can never become, like geometry, abstract systems of thought. The practice of venesection grew into a theory, but the theory was never dissociated from the practice; the results of the latter always remained to modify and invalidate whatever theory was framed to justify the practice. Thus medical science is never anything but inductive; both present and new facts ever accumulating do not allow it to stop, except momentarily, and rest on deduction. The theories which M. Poincaré criticises did and do allow long pauses in which, in absence of new facts and inference from them, they almost necessarily become purely abstract and deductive. But the constant reference of our science to the old and new facts in its field, although it saves it as a whole, does not save its theories from the usual fate; the reference, indeed, makes their life a short one. It would be even shorter if the science had a foundation all its own, if there was a science of life as such. We have had theories of life in medicine, and we all know how useless and unsatisfactory they proved; the only thing that can be said is, that not having any theory of life of any value, we can have no real medical science of life. Neither have we as a matter of fact; all our theories have been built up on chemical and mechanical theories which in themselves are as remote from life as astronomy. Our theories are in reality only variants of the theories M. Poincaré discusses. But so far from the latter being ephemeral the pure abstract form they early assumed in many cases give them permanent and unquestioned influence. They entered the sphere of medical science as masters; our facts had to be conformed to them and our theories have a scope and validity not their own.

In any case the position is an illogical one. There can be no science of life as long as the science of inorganic existence is put in its place, as long as the vital case is reduced to the non-vital and subject to its conditions. But there is a science of life, as such medical science, in a true sense if the facts of life reject this reduction. My object here is to show that they do reject it, and ever increasingly as medicine adhering to its ancient inductive basis holds fast to these facts in a perceptual sense, and never abandons them for the concepts of scientific theories which M. Poincaré truly states as ephemeral sooner or later.

As a matter of present experience there is no science of life for medical men just because, under the influence of these ephemeral theories, they allow themselves to drift away from their own proper facts, to misunderstand and even ignore them altogether. My position I conceive is a practical one, as an attempt to emancipate medical science from theories in the first place foreign to it, in the next vague ever changing and ephemeral in themselves.

The following statements express, sufficiently well, at least, for a short paper, the subordination of medical science to these theories, foreign to it and necessarily forbidding it independent status as a science of life.

"The metabolism of living substance upon which all life depends is conditioned by the existence of certain very labile compounds, which stand next to the proteids, and on account of their significance in life are best called biogens." Again, "The simple expression for the problem of all physiology" (and therefore of all pathology) "is—*The life process consists in the metabolism of proteids.*" (a)

In his text-book "On the Cell," O. Hertwig gives Pluger's definition—

"The vital force is the intra-molecular heat. The highly unstable molecules of albumin which are built up in the cell substance, and which become decomposed through a splitting up of the molecules—carbon-dioxide and nitrogenous bodies being chiefly formed—becoming continually regenerated and re-arranged." (b)

The theories of Metchnikoff as modified by himself, of Ehrlich and others, of immunity and assimilation, all rest on a more or less clear conception of chemical metabolism as given in these passages. I need not dwell on the commanding place these theories occupy in modern medicine. It would suit my purpose admirably to take the theory of chemical metabolism, and in general modern chemical theory as safe ground to go on, but as an honest reasoner, I cannot do so. I can only take it by hypothesis as sound. We have the right, however, to demand precision from chemical physiologists and pathologists, and that is enough. A mechanical and a chemical operation has a spontaneous form of its own in disposing matter, which in the general cosmical case is not free, but subject to fortuitous circumstances. Potassium and oxygen interact when free to do so, and the operation is a chemical spontaneity, but when the metal is sealed in a tube the chemical operation is prevented by what is not such an operation. If light acts on a silver salt in a tube a chemical operation ensues, but if the actinic rays are intercepted by non-chemical means, no change occurs. An endless series of examples might be given showing that, even in the inorganic field, mechanical and chemical spontaneity is not free, that, indeed, in the general case it occurs under conditions of constraint varying in degree up to total hindrance.

(a) "General Physiology." Max Vernon. Translated by F. S. Lee. Macmillan. P. 136. Italics in text.

(b) "The Cell." Dr. O. Hertwig. Translated by H. J. Campbell M.D. London. P. 127.

The position that life is dependent on chemical metabolism or that any free chemical operation goes on in the proteids giving either them or derivatives from them, is a singular error, as such precluding the existence of any science of life. The contradictory of the position would be that the constraint on mechanical and chemical spontaneity, which in the general field may be said to be fortuitous is not fortuitous, but specifically determined in the vital field. The grossness of the error made is seen in the actual fact that the products of vital operation are products neither of mechanical and chemical spontaneity nor of the inhibition or hindrance of such spontaneity, but of controlled constraint on both, products exhibiting permission, sufferance, inhibition, hindrance, within certain limits, on every form of physical activity. The human body and every cell component in it considered as cases in such activity are instances of this; no form of the activity either spontaneous or inhibited apart from concurrent control, always in evidence as long as life can be predicated, gives the cases.

One of the theories which is introduced into medical science or the science of life, is that of rigid determinism. But the theory is a foreign one to our science entering it only to destroy it. We are not concerned with any general principle of the kind, but with an imperfect induction giving us a group of facts under particular forms of determination, and our business is with the facts and their particular determinations, avoiding hasty generalisations. In the vital field, and particularly in pathology, our immediate concern, we should not allow chemical metabolism, which, as usually expressed in the text-books, means chemical spontaneity, to run away with us. In pure chemistry, particularly in its modern development, stereochemistry, the chemical spontaneity itself is supposed to be subject to mechanical interference or inhibition and inert or inactive molecules to interpose themselves in the way of molecules relatively active in respect of one another. What is called "steric hindrance" is supposed to occur when a foreign atom intrudes itself into a molecular group, and either drives out a native atom or is driven out by it. "The case is parallel to that of a person trying to force his way into a crowded room." (c) The relation of two active molecules to each other being the fact of chemical spontaneity, the fact of the inter-position of inert material between them preventing their inter-action is another fact of altogether different nature.

Both facts are represented in the proteids and all forms of living substance, the chemical spontaneity and its inhibition, and along with them as the specific vital fact their control and regulation. But the more important physical or non-vital fact is not the spontaneity but its inhibition, since when vital control ceases the proteid tends to take a form representing the spontaneity alone.

It would be far more consonant with our perceptual facts to say that the somatic proteids express not chemical metabolism or chemical inter-action, but inhibition of such inter-action. It is an error to state as chemical compounds what are really products contradicting the defined nature of such compounds. The chemical formula for the hæmoglobin of horses' blood is $C_{712}\ H_{1130}\ N_{214}\ O_{245}\ Fe\ S_2$ (Zinoffsky), but anything—the horse itself—could be put under a similar formula. If in the hæmoglobin the molecules of iron are partitioned off from those of oxygen and sulphur the body would not be a chemical compound, and its instability would not be a case in chemical equilibrium. Living, the body must be an energid, a store of energy; if it was a true chemical compound it would be a sink not a source of energy, and it becomes that and a chemical compound as it comes to express death or necrobiotic form. Energy, in equivalent material terms, means a definite mass actuated by particle velocity constrained by a boundary or something serving functionally as a boundary. A bottle with a pound weight of water in it, as a boundary, prevents the pound of water taking a configuration which it otherwise would as subject to the general environment, and the measure of the hindrance is what is called energy. A cortical nerve cell as a vessel constraining contents is an energid in exactly the same sense whatever other factors may intervene. In this simple concrete case energy is stored, not by allowing, but by disallowing an opposed mechanical spontaneity. In the same way life commands the energy of chemical affinity, not by allowing, but by inhibiting it; what it wants is energy to dispose after its own fashion, use any way biological necessity dictates. The vital unit is not the creature of or determined by anabolism and katabolism any more than a man is alive because he eats, drinks, and moves things about. Anabolism and katabolism in the vital field are not physical correlatives, but determined independently of one another by a specific vital operation, which is an antecedent determinant. The amount of oxygen burnt in a man's lungs in one hour is not the same as the amount in another hour, and the disposition of the oxygen is governed, not as a chemically spontaneous operation, but by varying biological necessity. To answer such necessity the antecedent potentiality in life transforms, as far as can be seen, every kind of energy, chemical into mechanical, *vice versa*, and so on. This has to be admitted, and we are not altogether in the dark as to the means whereby such transformations are effected. In every steam engine the energy of chemical and physical spontaneity must be constrained and inhibited by a boundary system in order to get transformation into the mechanical form. But analysis of the ashes in the furnace would not tell us what the transformation was or how effected; in the general case it could only express the resultants of chemical spontaneity. In physiology and pathology it may do more, but only when the products are taken under the condition of indicating transformation as the result of hindrance of chemical and physical spontaneity.

In biology, the general form of medical science, chemical metabolism, the intra-molecular heat, biogens and so on, have conventional place in text-books—that is all. The biologist, like the medical man, is so rigidly bound down to concrete perceptual facts, that physical and chemical theories only confuse and distract him as far as he allows them to do so. He keeps thus to the antecedent fact in life, to the germ and its environment in the egg-cell, and therefore to the general form of micro-organic existence, the legitimate extension of the subject. He has as a perceptual fact the unicellular organism and its differentiation into soma and vital unit or units. As he proceeds, instead of approaching the theory of chemical construction, he has to recede from it. He has to describe seeds capable of development into multi-cellular organisms as non-metabolic in respect of their environment, and content himself with a hypothesis of intra-molecular metabolism, whatever that may mean. The experiments of Koch and others seem conclusive of the fact that they are not, as long as living, in metabolic relation with the external environment, and it is evident that what restrains or hinders the relation is life; the vital hindrance removed, they interact with the environment and decay. The fact here is not the death of the vital unit itself; that may or may not be the case; all we can affirm is cessation of a specific influence over its somatic environment. But that influence primarily exerts itself on the mechanical structure of the soma; if that is broken down, the influence no longer restrains chemical spontaneity in it. The influence, however, is only functional in the id or vital unit; the existence of that form does not depend on its exerting energy, on its environment, or being energised by it. Of peculiar significance in pathology is the observation that the non-sporing typhoid bacillus, the bacilli coli communis, and staphylococcus pyogenes aureus retain their vitality when immersed for six months in liquid air at a temperature of − 190° C., and would probably at the absolute zero temperature. It would, indeed, be hasty to say that the organisms were frozen, or even that they exerted no energy to accommodate the medium to their condition of existence. In both the inorganic and organic field energy seems to be inversely as magnitude; an atom as an energid is far more powerful than a molecular group; a flea is a far more powerful animal than an elephant; and the muscular energy of a leech or worm far greater than that of a man. The typhoid bacillus in liquid air, even if not able to raise the temperature of a minute couche of air about it, may have the power of maintaining its own temperature; it would only be in higher degree the case of a man keeping at 98.5° in a medium at 40°. The essential point is that the micro-organism is immensely more powerful as an energid than the metazoan and than the soma the metazoan builds about itself. But, as is evident, this store of energy is a fact of its proper constitution; the demand for energy in the typhoid bacillus is a maximum in liquid air, while the energy of chemical association is, if not abolished, reduced to a minimum. The energy of the typhoid bacillus and its congeners under the condition must be directed to maintain their mechanical configuration, and that energy cannot be derived from chemical metabolism or kinesis, which, as far as we can see, does not exist at all.

(c) "Stereo-Chemistry." A. W. Stewart, D.Sc. Longmans. 1907. P. 314.

A fortiori, the conclusion would be stronger for the vital unit that its specific state is adiabatic—that is to say, allowing flow of energy neither into nor from it. That, of course, would be a case at limit, the general case being that there is varying efflux and influx always leaving a fixed quantity adiabatic. That, in material terms, would be an expression for the conservation of mass as the condition of conservation of energy. The drift of biological theory, as long as it keeps to its own facts, is irresistibly in this direction. The theory, leaving chemical and mechanical metabolism behind, goes back to a vital corpuscle or mass having specific determination of state which is intrinsic, and, as far as specific, incapable of change within the ascertained or probable limits of organic existence. What these limits in terms of space and time are we do not know, but do know that they have been very hastily assumed. Von Helmholtz and Lord Kelvin supposed that life may have come to our planet in a meteorite. If, however, the typhoid bacilli can live in a fluid at or near the absolute zero of temperature, and that an order of the organisms are anærobic, it may be that they exist in vacant space and in typical form as adiabatic energids. In liquid air the typhoid bacillus attains relative immortality, and it is possible that the typical state for the rudimentary micro-organism is changeless for an unchanging environment.

That micro-organic existence is not contradicted by the conditions of vacant space, that a vacuum at the absolute zero of temperature does not necessarily destroy every form of life, is, of course, an inference from a few facts; but, even so, it keeps biology to its own province by excluding the agents in chemical metabolism. The case, however, becomes an immediate one for human physiology and pathology if the typical form of the micro-organism is adiabatic, or in the ultimate case that of a self-contained energid. It is often useful to express for the sake of clearness the limit of a state or action, even though it may be given only under the form of approximation in our range of observation. In that range, however, adiabatism, as in the seed, resting spore, and the egg, is as much in evidence as any fact of metabolism, and is the primary vital fact, as metabolism, however defined, is not. But then the latter is the base of current theories which require the former to be ignored. The case illustrates the intrusion of physical theories into the vital field to obscure it by their own incompetence and partial character. The adiabatism of the egg is as plain a thing as that of a tin of preserved salmon or beef, and it is equally plain that it is obtained through life inhibiting chemical spontaneity. It is plain, again, that the typhoid bacillus, and, inferentially, the id or primary vital infinitesimal, exists not only in the human body, but in a much wider range of circumstance in passive or adiabatic form. The metabolic theory, to be logical, must express that as a particular adaptation to environment. The adaptation of the egg to environment, however, is response to chemical spontaneity giving the case of death or necrobiosis. The response of the vital energid to death is anabolism, but then anabolism is not a case of chemical inter-action, but dynamic continuity of inhibition of such inter-action visible in the whole range of the operation which goes on in the living egg and in the farther ontogenetical development. Darwin, Weismann, Hertwig, Roux and all biologists, as long as they keep to their own region of fact, whatever name they give the vital unit, describe it as a perceptual mass under a boundary, and its growth effected by extension and duplication of boundaries giving form as the result. "Die Form erscheint so in mancher Hinsicht als eine Function der Wacksthum der organischen Substanz." (*a*) The fact begins with the bending in of the blastosphere to form its duplicated cup, and ends with the vast area of boundary and boundary strain which the human brain presents, to take one organ alone. But all this only means the inhibition of mechanical spontaneity, and the storing of energy by occluding particles of mass under boundaries. This again necessarily implies breach of chemical spontaneity; bodies which, if free, would inter-act chemically are partitioned off from one another, and so are under constraint which is equivalent to stating as energids what are not such whenever chemical combination occurs.

That, in every case, is a fact and evidence of death, of life ceasing to exert its adiabatic power of retaining energy measured by mass under constraint to be disposed of according to biological necessity. The concurrence of life and death in organic substance will not confuse us when we grasp the fact that life, even in the dynamic case, is always adiabatic. The limiting case is given by the id or by the typhoid bacillus in liquid air. It is sufficient for the bacillus to retain under the condition such a measure of energy as shall preserve its mechanical configuration and therefore its life; it, or its soma, dies if it is triturated in the medium. In the medium it does not undergo fission, and neither is altered by it nor alters it. That, we will assume, is its normal or typical state, and farther that it may retain that state in very different environments, even in the human body. Transferred however to media acting specifically on it; so-called nutrient media, it has to meet the case of death or dissolution of its soma. In some cases, as when it enters the human blood stream it may be supposed to die, its soma being dissolved. On a nutrient medium, however, it does not die all out; its soma keeps on dying, reacting to the chemical spontaneity represented by the medium or its action; but the bacillus reacts by dividing and sub-dividing, since by so doing it preserves adiabatic energy and thereby its mechanical configuration. If the mass is halved, the energy being only in part a function of mass, is not halved; the continuous sub-division of the mass as it proceeds increases the adiabatic fund of energy on the principle that the energy is relatively greater for the smaller mass.

I say this merely to indicate that we are far from a general theory of micro-organic existence, so far, indeed, that it seems to me that no attempt is made to collate the known facts on which it might rest. The theory of chemical metabolism is, however, a positive obstacle in the way of any such theory, and our pathology is now almost entirely reduced to questions in chemical metabolism which hang very ill together. Logicians tell us that a half truth is to be met by denial *in toto*, and I will conclude by saying that the typhoid and tubercle bacilli—two very different types—are both typically non-pathogenic, that they exist in the human system as non-pathogenic, and that the study of them from that point of view would be one of great utility.

LORD HAVERSHAM, formerly Sir Arthur Hayter, is to be Chairman of the Joint Committee of both Houses of Parliament for considering the Government Poisons and Pharmacy Bill.

DIVERTICULA OF THE ILEUM RESULTING FROM TUBERCULOSIS AND ACCESSORY PANCREAS. (a)

By ALEXIS THOMSON, M.D., F.R.C.S.,
Assistant Surgeon, Royal Infirmary, Edinburgh, &c.

Diverticula may be met with almost throughout the whole length of the alimentary canal, though they are much more common in some regions than others. They are relatively frequent in the gullet, pharynx, ileum, and sigmoid flexure, rare in the stomach and duodenum, and have not been reported as occurring in the cæcum and ascending colon. Formerly they were divided into true and false diverticula, but since cases of acquired diverticula had been reported in which all the coats of the intestine, etc., had taken part, the distinction formerly drawn between the two forms was invalid. Pharyngeal pouches are not very uncommon about the region of the tonsil; these generally arise from some abnormality of development of the second branchial cleft. Next come pouches at the junction of the pharynx and œsophagus, where for anatomical reasons the wall is relatively weak. Pouching is also liable to occur at the level of the bifurcation of the trachea. Diverticulum of the stomach is rare; so also is that of the duodeunm. Sometimes, however they arise in this situation in the neighbourhood of Vater's ampulla; where there are remains of the fœtal pouches which go to form the liver and pancreas. In the jejunum diverticula are rare; in the appendix they arise chiefly in connection with previous appendicitis, with destruction of the muscular coats and weakening of the wall of the viscus. In the descending colon and sigmoid small diverticula not infrequently are met with, these being due to defects in the muscular coat. Acquired diverticula are in general caused by anything which impair the integrity of the muscular coat, or from traction from without. As regards the features of two cases of diverticulum recently met with, it may be said generally that any diverticulum of the ileum is apt to be put down as a Meckel's diverticulum; but probably, if all were carefully examined microscopically, this would turn out to be an error. In the cases in question tubercle was the cause of one, and an accessory pancreas of the other. The first case was that of a woman operated on on account of recurrent attacks of abdominal pain. On opening the abdomen, the appendix was found healthy, but there was a small diverticulum of the ileum, with an adhesion at its apex. The diverticulum was removed, and proved on microscopic examination to owe its existence to weakening of the wall of the bowel at that point from tuberculous deposits. The second case was that of a young man suffering from acute abdominal symptoms—peritonitis—with some features suggestive of acute pancreatitis. On opening the abdomen a diverticulum of the ileum and acute peritonitis were present. The diverticulum was removed, and the patient made a good recovery. In both these cases the operation completely relieved the symptoms. Microscopic preparations of the two diverticula showed, in the first case, well-marked tuberculosis, which had caused weakening of the bowel. In the second case there was an accessory pancreas in the wall of the intestine and outside the muscular coat, but under the peritoneal covering there was a second and larger mass of pancreatic tissue separated from the first by some of the longitudinal muscular fibres. Accessory pancreas is not a very rare lesion; aberrant portions of gland might be found in several parts of the alimentary canal, usually imbedded among the muscular fibres, and often possessed a duct opening into the lumen of the stomach or intestine. The microscopic features of this case are probably unique. The mass of pancreatic tissue lying about the muscular fibres is practically normal in appearance, and had, no doubt, a duct opening into the ileum. The second mass of pancreas, which formed the apex of the diverticulum, is totally different. There is, in the first place, a great increase in the stroma. Then the ducts are much more numerous than in the normal organ, giving much the appearance of a columnar epithelioma. The cells of the acini can here and there be seen undergoing transformation into ducts. In some cases islands of normal pancreatic cells are present, and close to these are masses of cells taking on an unmistakable malignant action. The case is a good example of Cohnheim's theory of the origin of cancer from an embryonic remnant.

OBSERVATION ON THE USE OF
INOCULATIONS OF BACTERIAL SUSPENSION. (a)

By L. C. PEEL RITCHIE, M.D., F.R.C.S. Edin.

Immunity is of two kinds—anti-microbial and anti-toxic, and only the former is considered here. For the production of anti-microbial immunity, injections of suspensions of dead bacilli are employed. Minute doses of poisonous bacteria cause a protective reaction out of all proportion to what is actually required, and the protective substances are therefore available for guarding against future infections of the same nature. Such inoculations are beneficial in the case of an existing disease, because Nature tends to control infectious processes by localising them, and we can produce and increase by inoculation the quality of specific anti-bacterial substance in the circulation. The plasma after inoculation is able to assist the leucocytes, for in cases of abscess, one finds that as a consequence of the inoculation the cells contain more bacteria than before. In chronic infections, such as tubercle, inoculation has little direct effect on bacteria; but, by keeping the blood rich in protective substances, extension of the disease from the local lesion is rendered unlikely. In inoculation treatment it is desirable to increase the circulation of the immunising plasma through the diseased area, as by artificially-induced hyperæmia. From being largely empirical, inoculation has been put on a more exact basis by Wright's researches. After a therapeutic dose of a bacterial suspension, there is in a healthy person a rise in the index. In an infected person this positive phase is preceded by a negative phase, or fall. It is less generally known that both in health and disease there is a very marked rise, reaching its maximum within six hours after inoculation. In giving inoculations of tuberculin, it is not sufficient to avoid the negative phase, but it is advisable to delay giving each successive injection until the effect of the preceding one has passed off. If this be done, the treatment may be continued for months or years without the occurrence of a prolonged negative stage. The author adopts the method of weighing the bacteria used for suspensions, and finds that, while the ordinary dose of staphylococci weighs 1-10 mgr., a dose of 1-1,000 mgr. is quite as satisfactory. The general idea that it is better to prepare the vaccine from the patient's own streptococci, etc., is not borne out by the author's experience; infections respond equally well to the use of a stock suspension. In chronic infections doses of 1-1,000 mgr. should be given at intervals of two, then three, then four weeks, continuing at that rate for six months. The short interval between the first two or three inoculations is to overcome the negative phase due to the obscure feature of immunisation known as hypersusceptibility. In acute conditions doses of 1-4,000 to 1-2,000 mgr. are repeated every eight or ten days. In children under fourteen these doses are halved, and in infants divided by ten. In treating tuberculosis, fever, in the absence of a mixed infection, must be allowed to subside; if a mixed infection be present, the secondarily infecting organism must also be inoculated. Early glands do well; those which are caseating require a long treatment. If infecting joints are got early, they may recover with no loss of mobility. Skin lesions are intractable unless appropriate local measures are conjoined with inoculation of tuberculin. Cases of multiple tubercular infection are especially suitable for treatment, on account of the risk of extension entailed by operation. Staphylococcal inoculation is beneficial in cases of boil, abscess and acne. Contrary to the usual opinion, Dr. Ritchie thought that streptococcal infections were particularly amenable to inoculations with a stock vaccine. The prophylactic use of staphylo- and streptococcal inoculations prior to operation had also been found extremely succesful.

CLINICAL RECORDS.

CASE OF PREGNANCY COMPLICATED WITH LARGE RETROPERITONEAL AND SUBLIGAMENTOUS FIBROMYOMA.

By JOHN H. DAUBER, M.B.Oxon., M.R.C.P.Lond.,
Gynæcologist, Hospital for Women, Soho.

Mrs. C., æt. 31, married three months, was brought to me on December 11th last year by one of her medical advisers. The last catamenial period occurred on September 16th, previously to which she had always been regular, and the flow normal. No abdominal swelling was noticed until the spring of last year. Since then it had rapidly increased, especially latterly.

The patient complained of being so large a size, and as she considered she was only three months pregnant, she feared there was something wrong. She had already consulted two other medical men, who considered she was probably pregnant, but that the pregnancy was abnormal, being complicated by a large tumour which would prevent her going to full term, and that an operation was necessary; so that it was only left to me to confirm or otherwise the diagnosis already made and the treatment suggested. The patient was a small, slightly-made woman; bright and alert, not ill at all. Upon examination it was found that the abdomen was occupied by a large irregular solid tumour rising almost to the ensiform cartilage. It lay mostly to the left of the middle line. Its right border was clearly defined about two inches to the right of the umbilicus. No fœtal movements were detected, no fœtal heart sounds heard, no rhythmical contractions felt, but over the whole of the tumour a loud hæmic bruit was heard. The breasts were enlarged and tender; the areola of pregnancy was marked, but no secretion was obtained. Per vaginam, a hard round mass was felt coming down into the pelvis to within two inches of the vaginal outlet and continuous with the abdominal tumour. It was quite fixed. It pushed the vagina—which was narrowed and greatly elongated—to the right, so that the examining digit passed it with difficulty The right vaginal fornix, together with the cervix, was drawn up completely out of reach. The uterus could not be made out as distinct from the tumour. Where it lay, or to what extent it was involved in the tumour, could not be ascertained.

The condition seemed to be a three months' pregnancy, complicated by a large fibroid. It was quite evident that pregnancy could not go on to full term, as the pelvis was entirely blocked, and the abdomen occupied already by a tumour as large as a uterus nine months pregnant. I agreed with the previous diagnosis, and advised early operation.

Eight days later, on December 20th, in a nursing home, with Dr. Mansell-Moullin, who kindly assisted me, and Mr. Ogle, who gave the anæsthetic, I operated. Dr. Card, the patient's doctor, and another medical man, were also present. A median incision was made from above the pubes to half-way between the umbilicus and the ensiform cartilage. A large irregular solid tumour was exposed, lying to the left and extending from deep in the pelvis to under the arch of the diaphragm. It was fixed and retroperitoneal throughout. Somewhat behind, and overlapped by the tumour, in the right iliac fossa, lay the pregnant uterus adherent to the tumour by its cervix, which was greatly lengthened. The intestines were adherent over the upper part of the tumour by many adhesions. It took some little time to clamp, tie off, and free them. In peeling off a piece of gut, the capsule of the tumour was torn, and as it was obvious that it would shell out of its bed, the rent was enlarged, a hand passed in, and enucleation rapidly proceeded with. In a few seconds it was free, with the exception of its pedicle, which, the size of a small wrist, had a firm attachment to the neck of the uterus. The hæmorrhage from the bed of the tumour was very great. It would be no exaggeration to describe it as appalling except that nothing appals an operator; so profuse was it that we feared the patient would die then and there on the table. Large swabs, gauze packing, forceps, were rapidly applied, the base of the tumour and neck of the uterus grasped, and the aorta compressed, with the result that the hæmorrhage was controlled to some extent. The base of the tumour was then cut through, as it would not shell out, and with it the left uterine artery, which had been previously seized with forceps. An attempt was now made to finish off the operation and save the uterus, but, in spite of underpinning, ligature of many vessels, deep sutures into the cervix, etc., it was found impossible to control the hæmorrhage sufficiently rapidly. There was little time for further deliberation; immediate action was imperative. So, with much regret, I amputated the uterus supravaginally. The cervix had been so lengthened, cut into, and weakened by the removal of the tumour, that the body of the uterus previous to amputation hung much like a cherry on a stalk. The removal of the uterus enabled one to deal successfully with the hæmorrhage.

The uterus was sacrificed for these two reasons:—(1) The difficulty of controlling the hæmorrhage, which had already been excessive; and (2) because to leave the uterus with its elongated and damaged cervix seemed to be adding a risk of the utmost gravity to a case already sufficiently serious. I may say that Dr. Mansell-Moullin fully concurred in this view.

It now merely remained to cut away the superfluous peritoneum which had covered the tumour, and to sew the cut edges together; but upon removing the gauze plugging from the cavity, a great burst of hæmorrhage again occurred. Many large vessels had yet to be tied, and at one time it appeared that gauze plugging would have to be left in. This eventually proved to be unnecessary. The abdominal wound was closed in three layers of continuous sutures. I used "Triolet" catgut throughout the operation.

For the first few days the patient suffered considerably from shock, and any further complication, such as miscarriage or uterine hæmorrhage, would, in my opinion, have been most undesirable, to say the least of it. For the rest, the recovery was uninterrupted and complete. The stitches were removed on the eighth day, and the patient was sitting up in bed towards the end of the second week

Cases of pregnancy complicated by fibroid tumour are always interesting, because there is a double issue at stake, and it was a great regret to me that I was unable to save the uterus in this case. The fact that the tumour was beneath the left broad ligament, and had then burrowed up behind the peritoneum as far as the left kidney created the difficulty. Rapidity of growth and extreme vascularity one expects to find together. Pregnancy was a further stimulus in both these directions, for it is often possible to enucleate large broad ligament fibroids almost bloodlessly.

---

(1) Note of a case read before the Royal Society of Medicine, March 12th, 1908.

Although there appears to be a consensus of opinion in the Section that fibro-myomata of the uterus complicating pregnancy should not be submitted to operation except for the most cogent reasons, in this case there was no alternative for the reasons stated. Although the case did remarkably well, it was not entirely satisfactory in that I did not succeed in saving the uterus.

OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Mitral Stenosis.

By Leonard Williams, M.D., M.R.C.P.,

Assistant Physician to the Hospital; Physician to the French Hospital in London.

This woman, æt. 32, presents a very good object lesson. We are frequently told that we ought not to pronounce a heart to be in a satisfactory condition until we have examined it with the patient lying down, as well as standing up. That is a piece of advice which the exigencies of busy work, either in the out-patient room or in general practice causes us too often to neglect. But its value is admirably illustrated by this patient.

She came to us some time ago complaining of bronchitis, which was accompanied by a quite unusual degree of breathlessness Before I examined her I expected to find the lungs emphysematous, and the bronchitis depending thereon. When I did examine her, however, I found the lungs practically free from emphysema, but there was ample evidence of a "bronchitis" at both bases behind. The cardiac condition seemed ambiguous; there was an enlarged right ventricle and an accentuated sound at the pulmonary base, which seemed at first sight to support the suggestion of emphysema. But the emphysema being absent, we had to look for some other cause. Whilst she was standing, that other cause did not reveal itself, but on laying her down she developed a fairly typical presystolic murmur at the apex. Indeed, when I first heard it, so pronounced was it, that I thought I must have missed it in the upright posture from sheer carelessness, but on standing her up again, the murmur once more disappeared. This condition still persists, and any of you can satisfy himself of the fact that in the recumbent posture she has a quite unmistakable presystolic murmur, whereas in the upright posture the characteristic sounds of mitral stenosis altogether disappear.

Now I need hardly remind you that the presystolic, or crescendo murmur as it is sometimes called, is by no means necessary to establish a diagnosis of constriction at the mitral valve. It is indeed only when that constriction has progressed to a certain point that the murmur developes. The first auscultatory phenomenon which announces the presence of a constriction at this point is the double second sound heard in the neighbourhood of the apex. Various explanations are offered as to the meaning of this double second sound. The one which I personally favour is that offered originally by Potain, which is as follows:—The ventricle contracts producing the first sound; the semilunar valves close, causing the second sound. Immediately after the second sound, the auricle contracts, and in contracting forces the blood through the mitral valve. If this valve is stiffened, as in the case of commencing mitral stenosis it invariably is the forcing of the blood from auricle to ventricle through the stiffened valve will give rise to an added sound. The French called it "le claquement de l'ouverture de la mitrale." That is the first step in the evolution of the sound of mitral stenosis. The next step is the typical rough crescendo presystolic murmur which the late Sir William Gairdner used always to call the "auricular systolic murmur," which is present in this woman's case. The third stage, which precedes death for a variable time, is presented by a single sound exceedingly loud and sharp, which is to be heard all over the cardiac area. The murmurs have been suppressed, and the second sound, though it may still be audible at the pulmonary cartilage, is inaudible elsewhere. That these auscultatory phenomena pass through these various stages should help to remind us of a fact which is too often forgotten, and which from the point of view of prognosis is of paramount importance, namely, that mitral stenosis is essentially a progressive disease.

Rheumatic endocarditis occurring, say, at about fifteen years of age, and causing a constriction at the mitral valve, may, under favourable circumstances, give rise to no symptoms for about fifteen years, that is, until the patient has reached thirty. At about this age, however, certain difficulties are sure to arise. The most common, of course, is bronchitis, but long before the bronchitis becomes at all troublesome the patient will have noticed an increasing amount of dyspnœa on unusual exertion. Another not altogether uncommon manifestation of mitral stenosis, even in its earlier stages, is hæmoptysis. A former President of the Royal College of Physicians was fond of asking candidates for the membership the followng question: "A red-headed woman, æt. 30, suddenly has a violent hæmoptysis, what is the matter with her?" A large majority of the candidates would reply, "Tubercle," but that was not the right answer. The right answer was "Mitral stenosis." It is said to be a fact that red-haired people are more subject to rheumatism than those of dark complexion. Whether or not this be the case it is undoubtedly a fact that at the age of thirty, people who have been the subject of mitral stenosis for many years frequently experience their first unmistakable evidences of cardiac embarrassment. For we must remember that, as the French put it, "une lesion d'orifice n'est pas une maladie de cœur." As long as the orificial lesion is adequately compensated, a person cannot truthfully be said to be suffering from disease of the heart; though he has, no doubt, a mechanical disability which renders him more likely to suffer from cardiac disturbance than those whose orifices are perfectly sound. But so long as the compensation is adequately maintained, such a person requires no treatment other than that which is prophylactic, that is to say, he must be advised to put as little strain upon his cardiac vascular system as possible, and to pay particular attention to the ordinary rules of healthy living.

The danger signals, then, in mitral stenosis are to be found primarily in the lungs: breathlessness, bronchitis, hæmoptysis. But there is another organ which should be investigated, and which is capable of giving us a great deal of useful information long before the danger signals in the lungs become obtrusive. This organ is the liver. The liver may be regarded as the overflow reservoir of the right ventricle. When the right ventricle is pumping against an undue amount of obstruction, it will refuse to admit more blood into its cavity than it can conveniently deal with, and the superfluous blood is returned to the reservoir beneath the right costal arch. This being so, it is evident that the enlargement, especially the tender enlargement of the liver in cases of mitral stenosis, is a warning which, if properly heeded, may save all the troubles and anxieties of a period of broken compensation. The way to deal with a position of that kind, or, indeed, with a mitral stenosis in any of its stages, where it is producing symptoms, is to relieve the pressure on the right heart by venesection and purgatives. Venesection is unfortunately a therapeutic measure of which a great number of people are unduly afraid, and where one comes across such a patient, as one not infrequently does, a very good substitute may be found in the application of leeches. Many people who will not hear of venesection still submit cheerfully to the application of any number of leeches. A practical point in connection with the application of leeches is always to place them over some bony substance. The object of this is to facilitate the checking of the hæmorrhage when the leeches are removed. A little pressure, especially when combined with cold will always ensure this, if there is a hard substance underneath; whereas, if they are applied over the more or less flaccid abdominal organs, the bleeding will often give rise to unnecessary alarm on the part of the patient, and decide him to refuse to submit to the application of leeches on some other occasion, where the necessity for them may be even more urgent.

With regard to purgatives, one of the best is the old-fashioned, and unduly despised, sulphate of magnesium. Dessertspoonful doses of a saturated solution of this salt in water, twice or even three times a day, will produce a very active catharsis, which, after bleeding, is one of the surest methods of relieving the hepatic congestion of mitral stenosis.

Digitalis is, of course, the best heart tonic to use in these cases, but it is useless to exhibit the drug until the hepatic congestion has been adequately dealt with by one or other of the above means.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

DOUBLE INGUINAL HERNIA.—OPERATION THROUGH A SINGLE INCISION.—**MR. ARTHUR EDMUNDS** operated on a man, æt. 22, with a small inguinal hernia on the right side, and a bubonocele on the left. The patient was in excellent health, and apart from the herniæ, exhibited nothing abnormal. The incisions for inguinal hernia, Mr. Edmunds said, are of two varieties: in the first the incision is made along the line of the canal over the upper part of the sac, and is kept as far as possible away from the scrotum; in the second a flap, usually with its concavity downwards, is reflected, so as to expose the area of the abdominal wall in the region of the rings. The object of such a flap is to carry the line of the incision in the superficial structures away from the deep stitches, so that if the wound becomes infected after the operation owing to a soiled or displaced dressing, there is a reasonable prospect of the muscles stitches remaining intact. A flap incision, while possessing this undoubtedly great advantage, necessitates more division of the skin than the straight method, and in those cases in which the operation is performed on both sides, it will be found that there is only a bridge of skin about an inch wide between the two incisions. In the present case an incision similar to the one which finds favour with many surgeons for operations on the pelvis was made: it commenced over or just internal to the internal abdominal ring on the right side, and extended in a curve following the line of cleavage of the skin of the abdominal wall until it reached the corresponding point on the opposite side. The line of incision thus made lay almost parallel to Poupart's ligament on each side, and crossed the middle line about an inch above the upper border of the symphysis pubis. The incision was deepened until the deep fascia was exposed, when it was found that most excellent access could be obtained to inguinal rings on both sides. By retracting the incisions first to one side and then to the other, ample room was obtained for the performance of the operation. This was carried out on both sides in the usual manner, and the wound was closed with a continuous suture. Mr. Edmunds remarked that it was evident that this type of incision was a perfectly efficient method over the more orthodox procedure. The incision lay in the line of the cleavage of the skin, and consequently has less tendency to stretch, and heals slightly more rapidly. In consequence of this the scar left by the operation is much less noticeable, indeed, it lies almost completely within the area of the pubic hairs, so that subsequently it would be difficult to find it without a very searching examination. These points were, of course, unimportant, although it must be admitted they would appeal to some types of patients; the main advantage of the incision consisted in the free exposure of the upper part of the sac on its inner aspect, that is to say, where it lies against the symphysis pubis. The disadvantage of the incision is, without doubt, that in the event of sepsis occurring there would be a greater likelihood of serious trouble; there is, however, no special liability to sepsis, as the wound lies well away from the perinæum, and there should be no difficulty in keeping it aseptic.

TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, MARCH 12TH, 1908.

The President, Dr. **HERBERT SPENCER**, in the Chair.

DR. **WALTER SWAYNE** read a short communication on

MYOMECTOMY DURING PREGNANCY,

and described two cases operated on by him. CASE I.—A primipara, æt. 40, pregnant five months, had a solid, rapidly increasing painful tumour growing from the fundus uteri. After laparotomy, a pedunculated fibroid the size of an adult head was removed from the fundus. The flattened pedicle was transfixed, and the peritoneum sewn over it. A smaller fibroid, which was sessile, and situated behind and below the first, was also enucleated. Recovery was uninterrupted. Pregnancy had not been interrupted two months later, after which the patient was lost sight of. CASE II.—Multipara, æt. 35; pregnant 4½ months, with abdominal pain and a bilobed tumour rising out of the pelvis, the left lobe hard, the right soft and elastic. Laparotomy showed a fibroid growing from the right cornu of the pregnant uterus, which had undergone axial rotation, so that the fibroid lay on the left. The rotation was untwisted with some difficulty, and the fibroid was then enucleated. Pregnancy was interrupted a month after the patient left the hospital. Dr. Swayne pointed out that fibroids of the pregnant uterus require operation if causing pain, pressure symptoms, axial rotation of the uterus, or symptoms of twisted pedicle. Rapid increase with pain may point to degeneration. Pregnancy is not necessarily interrupted. Accurate apposition of the gap in the uterine wall is of great importance.

Dr. J. H. **DAUBER** communicated a case of pregnancy complicated by a large and fixed

RETROPERITONEAL FIBROMYOMA,

which completely blocked the pelvis, besides filling the abdomen. (This case is fully reported in another column, under the heading of "Clinical Records.")

In the discussion on these communications, the **PRESIDENT** (Dr. Herbert Spencer) said that, while not criticising the three cases reported, in which the operations were done for definite and serious indications, he felt bound to express his strong opinion that operations in the case of fibroids complicating pregnancy were rarely called for, and that myomectomy, which was occasionally urgently demanded in the case of very large, or impacted, or rotated tumours, was in relation to the frequent occurrence of this complication of pregnancy, very rarely required, and, as the cases exhibited that night showed, was attended by considerable risk. When practicable, the operation should be postponed till the child was viable.

Dr. F. H. **CHAMPNEYS** entirely endorsed the remarks made by the President. He had himself had a long experience of pregnancies complicated by fibroids. It was true that in exceptional cases he had been compelled to adopt serious measures, such as Cæsarean section, but he had frequently been consulted in cases in which the presence of a fibroid had caused alarm to the medical practitioner, but, without any interference, the patients had borne, not one child, but a series, with perfect ease and safety. In his experience the cases requiring serious interference were extremely rare.

Dr. G. E. **Herman** agreed with the last speaker that the mortality of myomectomy in pregnancy, as quoted in the statistics mentioned by Dr. Swayne, was much too high. He narrated a case where he had enucleated a fibroid from a pregnant uterus, and the woman was delivered six months later of a full-term child.

Dr. **Amand Routh** agreed with Dr. Swayne's statement that fibroids complicating pregnancy should not be interfered with unless producing urgent symptoms. Unfortunately, Dr. Swayne had quoted statistics, somewhat obsolete in date, tending to show that fibroids were so serious a complication of pregnancy that operations were frequently justifiable. Dr. Routh thought these statistics quite unreliable. He had collected statistics (*British Medical Journal*, Oct. 3rd, 1903) showing that the maternal mortality of such cases under modern methods was only slightly in excess of the normal, and that the danger to life was not so much due to risks during labour, but to sepsis afterwards, for if the endometrium became infected, a sub-mucous or intra-mural fibroid almost always became infected also. He showed that abortion did not more often occur where fibroids were present, though labour often ensued a few weeks before full time, and urged strongly that no operation should be performed till fœtal viability, unless absolutely essential, so as to save the two lives involved. He had only twice had to perform Cæsarean hysterectomy at or near full term, and never at an earlier date, though he had seen many cases of fibroids blocking the pelvis in the early months. The fibroids in such cases almost invariably underwent flattening and softening (*assouplissement*), and were gradually or suddenly displaced out of the pelvis, sometimes as late as the onset of labour itself, and labour spontaneously occurred without assistance.

Dr. T. W. **Eden** agreed with the previous speakers as to the rarity with which serious complications occurred when women with fibroids became pregnant, and deprecated the view sometimes advanced that pregnant women with fibroids necessarily went in peril of their lives.

Dr. **Arthur Giles** said that speaking in generalities would lead to confusion and inaccuracy. To say that the complication of fibroids and pregnancy was generally unimportant was as much beside the mark as to say that it was generally dangerous. The existence of fundal fibroids might make no difference to pregnancy or labour, but cervical fibroids impacted in the pelvis were in a totally different category. He alluded to a case in which he had removed a fibroid from the left broad ligament in a woman 4½ months pregnant. He experienced great difficulty in stopping the bleeding, and though he succeeded at the time, it recurred later, necessitating the removal of the uterus, as in Dr. Dauber's case.

A short communication was read by Dr. **Russell Andrews** and Dr. **Drummond Maxwell** on

A CASE OF DIFFICULT LABOUR,

with remarks on the frozen sections of the uterus. The patient had been in labour for 2½ days before the resident accoucheur was sent for. He found a very large decomposing child presenting by the vertex. Attempts at craniotomy and cephalotripsy resulted in the whole of the head being pulled off, and traction on the arms pulled both of them off. An attempt at version failed, the foot coming away without any alteration of position being effected. The patient was then sent into the London Hospital. When Dr. Andrews saw her, the uterus was in a state of tonic contraction. He cut through both clavicles, perforated the chest, and removed the heart and lungs, perforated the diaphragm, and removed the liver and intestines. In spite of effecting diminution of the size of the child, no form of traction applied by every conceivable variety of hook and forceps was successful, and attempts at version met with no more success. It was impossible to cut through the fœtal spine. At last, after 1½ hours hard work, realising that he could not deliver per vaginam, he removed the uterus with the child *in situ*, preferring hysterectomy to leaving the patient undelivered with the uterus in a state of tonic contraction. The patient died the next day. The child, who had apparently reached the age of 44 weeks, must have weighed not less than 13 lbs. Frozen sections of the uterus, with fœtus *in situ*, were exhibited. A well-marked ridge, projecting into the cavity of the uterus, was the subject of considerable discussion, it being the opinion of the authors of the paper that this represented the retraction ring. Post-maturity of the fœtus was discussed, and the recorded cases criticised. Sections of the placenta were also shown, but did not throw any light on the etiology and pathology of the condition.

Dr. F. H. **Champneys** said he had felt contraction rings round various parts of the uterus, in some cases round one of the uterine cornua. The experiments of Kleinwäechter showed that spontaneous delivery occurred in some of the most unpromising cases of obstructed labour. In such a case as that under discussion, where the patient was already septic, the choice of treatment was one of great difficulty.

Dr. W. S. A. **Griffith** suggested that the probable cause of the difficulty in delivery was not in the uterus, but in the macerated condition of the fœtus. He wished to emphasise the value of version as a means of delivery after craniotomy if the uterus was not in a state of tonic contraction.

Dr. T. W. **Eden** remarked that the term contraction ring used by the authors was inaccurate; it should be called the retraction ring. He could not accept the view advanced by them as to the formation of this ring that it was the result of moulding on a body groove.

Dr. **Andrews** and Dr. **Maxwell** replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, February 28th, 1908.

Mr. Seton Pringle, F.R.C.S., in the Chair.

SOME CASES OF GALL-STONES.

Mr. **Kennedy**, in his paper on gall-stones, laid stress on the fact that the only treatment of avail is operative. He illustrated by a case the difficulty of diagnosing gall-stones when the symptoms may be altogether gastric in character. He mentioned three cases of obstruction to the common bile-duct, upon which he had successfully operated, one in which the obstruction was caused by a single calculus weighing 50 grains—the obstruction was present for three and a half years; another in which six calculi were removed from the common bile-duct. This patient had had perforation of the gall-bladder and peritonitis about six months previously, for which Mr. Kennedy had also operated. The third case was an old lady who had apparently obstruction to the common bile-duct produced by chronic inflammatory trouble in the pancreas. A few points were mentioned dealing with the differential diagnosis between common duct obstruction produced by calculi and that produced by pancreatitis. Mr. Kennedy also gave a short account of two cases in which he had performed cholecystectomy. In both cases the cystic duct was obstructed by a calculus, and numbers of calculi were present in the gall-bladder.

The **Secretary** said Mr. Kennedy had well-expressed surgical opinion with regard to the presence of gall-stone when he said it was no more safe to leave a gall-stone in the gall-bladder than to leave a suppurating appendix inside the abdomen. That had been impressed on him by several cases which he briefly recounted. He agreed that the condition was one which should be put under the care of a surgeon, not a physician. Recently he had removed gall-bladders more often than formerly, as he had had experience of a recurrence of gall-stones in some gall-bladders which he had opened and drained. If the gall-bladder was found very much thickened and distended, and a stone was found in the cystic duct, he thought these were indications for the removal of the gall-bladder. There was a danger of malignant disease with the thickening, and there would be considerable doubt as to whether such had not already started. If a stone had been lodged in the cystic duct for some time, even if it could be removed at the operation, the probabilities of a stricture forming and resulting in a permanent mucous fistula were very great, and could be obviated by the removal of the gall-bladder at the time of the operation.

Mr. **Kennedy**, in reply, said it was by no means proved that the removal of the gall-bladder would prevent a recurrence of gall-stones.

THE SURGICAL TREATMENT OF EXOPHTHALMIC GOITRE.

Mr. **William Taylor** read the notes of a case of Graves' disease treated by removal of the right lateral lobe and isthmus of the thyroid gland. The case was that of a young girl, æt. 24, who had been suffering from the phenomena characteristic of Graves' disease for six years. Both eyes were very prominent, the heart's action was rapid, and palpitations were very distressing on the slightest exertion; muscular tremors were well marked, and her nervousness was so bad that she could scarcely speak intelligibly. The thyroid gland was enlarged, but the enlargement was much greater on the right side. Medicinal treatment had been tried for the six years she was affected, but without any beneficial effect. Her condition was steadily becoming worse, and she was compelled to give up her business, which was that of a dressmaker. After admission into the Meath Hospital, under Mr. Taylor's care, she was kept quiet in bed for three weeks prior to operation. During that time her pulse varied from 120 to 136 beats per minute. Under chloroform anæsthesia preceded by a hypodermic injection of morphin 1-6th gr., and atropin 1-100th gr., the right lobe and isthmus of the thyroid gland were removed. The operation presented no unusual feature of interest. There was very little blood lost, and the operation was well borne. The pulse during the subsequent 24 hours varied from 120 to 140 per minute, and the temperature rose to 101.4°. On the second day the temperature fell to normal, and the pulse averaged 120 beats to the minute. The drainage tube was removed on the third day, and the sutures on the sixth day. The pulse gradually fell in frequency till the tenth day, when the record was 78 beats to the minute. On that day she left for the convalescent home. On examination 20 months after operation, the patient's condition was in every respect quite satisfactory. Her nervousness had disappeared, there were no muscular tremors, she never got any attacks of palpitation, her pulse averaged 80 to the minute, and her exophthalmos—though still present—was much less marked. The girl expressed herself as quite well in every respect, save for the slight prominence of her eyes, and she was working daily at her business. Mr. Taylor then discussed the treatment of Graves' disease, characterising the treatment by drugs as empirical, while the method of treatment by feeding patients so affected upon the milk of thyroidectomised goats could only be palliative, and in no sense curative. Similarly, treatment by injection of the serum of sheep whose thyroid glands had been removed, as well as the treatment by giving rodogen, could scarcely be considered more than palliative. Operative treatment showed the best results, and when undertaken in an early stage, before the heart became disorganised and degenerated, the mortality attending it was but little in excess of partial thyroidectomy for simple colloid goître. The operation should be that of the removal of an entire lobe and the isthmus. One thus removed the source of the mischief by removing the organ in which the disease has its localisation. The degree of amelioration of the symptoms was in direct proportion to the amount of hypertrophied gland tissue removed or destroyed by the operation. Operation in an early stage can cure the patient, but operation in severe and advanced cases, provided the heart is not too disorganised to render such a procedure extremely hazardous, can only be expected to ameliorate the symptoms. Thus it is essential that the operation of partial thyroidectomy should be advocated and undertaken in an early stage of the disease.

Mr. L. G. **Gunn** also read a note on the SURGICAL TREATMENT OF EXOPHTHALMIC GOITRE, dealing mainly with the pathology of Graves' disease. He thought that the parathyroids were primarily affected; the enlargement of the thyroid followed. The microscopic appearances of the gland in the early stages of the disease are not distinguishable from those of simple goître; in the later stages of the disease the appearance of the exophthalmic goître under the microscope is unmistakable. Mr. Gunn then briefly related three cases of Graves' disease in which partial thyroidectomies had been done. Two of these had been most successful, but the third died from subacute thyroidism ten days after the operation. Mr. Gunn thought that operation, while undoubtedly attended with risk, holds out the best prospect of cure for the patient. The use of cocaine as an anæsthetic was not approved, the author holding that chloroform was no more dangerous for the patient, and far more comfortable for the operator.

Dr. **Stokes** inquired as to the average comparative mortality of the medical and surgical treatment of exophthalmic goître. He also wished to know if the communicators could explain how it was that, in the worst cases, the pathological changes were those of atrophy, the gland apparently removed itself, and yet those were the cases which died He asked also if any pathological changes had been found in the parathyroids?

Dr. **Kirkpatrick** said he did not think physicians would raise much objection to patients suffering from exophthalmic goître being taken from under their care, provided the surgeon could give better results. But he did not think that surgeons had yet got a method of treatment which was any more satisfactory than the medical. In order to prove curative, operation would have to be undertaken before serious symptoms had arisen; and, in order to be able to recommend patients to submit to operation at an early stage, the operation must be a comparatively safe one, and one from which good results could be promised. At present, however, the mortality of the operation was considerable, and permanent cure was not by any means established. Before they could come to any conclusion on the disease, something more would have to be known of its pathology and causation. The question of anæsthesia was of great importance. He believed that the mortality under general anæsthesia would be found to be greater than under local anæsthesia. Although it was not possible to get complete freedom from pain by any local anæsthetic, he thought they could get a working anæsthesia which would, on the whole, give a better result than a general anæsthesia. Of all forms of anæsthetic, chloroform was the most dangerous in such cases. He did not believe it was correct teaching that there was much less congestion and cyanosis, as well as bleeding, with chloroform than with ether. If the ether anæsthesia was satisfactory, and was not too deep, it would, to his mind, be very much safer than chloroform.

The **Secretary** said that although there was considerable question as to the pathology of exophthalmic goître, there was no question as to the pathological change from which the symptoms arose, viz., an increased production of thyroid extract. The case for the removal of the source had received additional support in the instances brought forward in the papers which had been read, but it was only by comparing results in a large series of cases which were operated on with those in which there was no operation that any conclusion could be arrived at. In ordinary goître he used ether anæsthesia. One of the results of thyroidism was to affect the cardiac muscle, and since chloroform had a very depressing effect on the cardiac muscle he preferred ether.

Mr. **Kennedy** attributed considerable importance to the position of the patient during operation. He believed that many deaths had occurred through interference with the recurrent laryngeal nerve. The danger of thyroidism was greater the more gland was left. To get a good result they had to remove practically the whole of the gland. The central lobe would be quite sufficient for the needs of the patient afterwards. If the surgeon got the case before pathological changes had occurred in other organs, the cure of the disease could be practically assured.

The **Chairman** was inclined to agree that local anæsthesia was the safest, but he would rather use a general anæsthetic in this country. Kocher's patients were bound hand and foot, and were in a much better state of surgical training than could be got in Dublin.

Mr. **Taylor**, in reply, said he was not aware of the comparative mortality of surgical and medical treatment. It was the few cases that got well without apparently any treatment that prevented cases being handed over to the surgeon at an early stage. Recent experience had led him to prefer ether anæsthesia by the open method.

Mr. **Gunn**, in reply, said that fibrous changes had been described in the parathyroids.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held March 11th, 1908.

The President, Dr. James Ritchie, in the Chair.

Mr. George Chiene showed two patients operated on for perforated gastric ulcer, in whom the plan of complete closure of the abdominal wound, without drainage, had been adopted. In both cases primary union had resulted. Such cases showed how great was the power of the peritoneum in dealing with infected material.

Mr. **Alexis Thomson** showed a boy, æt. 16, who was unable to extend his elbow completely. The condition had been in existence for several months; there was no history of accident, and no signs of disease of the elbow-joint were present. Skiagrams showed the limitation of movement was due to a slight displacement inwards of the epiphyses of the olecranon. As the condition was giving rise to no discomfort operation had been declined.

Dr. F. M. **Graham** showed a photograph and skiagram of a case of absence of both forearms.

Mr. **Alexis Thomson** read a paper on "Diverticula of the Ileum," an abstract of which will be found on p. 345 of the present issue.

Mr. **Wallace** and Mr. **Scot Skirving** discussed the paper.

Dr. A. **Walker** read a paper on

THE PROVISION OF SANATORIA FOR THE TREATMENT OF PHTHISIS AMONG THE POORER CLASSES.

His interest in the question was, he said, a very personal one, because in his youth he had been threatened with phthisis, and had been compelled to relinquish a city practice for that reason. He proposed to limit his remarks chiefly to the financial aspect of the question, and to eliminate from discussion such important topics as the dispensary for phthisis, methods of cure, and the question of the segregation of advanced infectious cases. The discovery of the tubercle bacillus and its life history had revolutionised our opinions as to the cause and treatment of the disease. We knew that the bacillus was readily destroyed by air and sunlight, though in its dried state, like other spore-bearing organisms, it was very resistant. Both pathology and vital statistics showed that Nature plays a very important *rôle* in the prevention and cure of phthisis. Post-mortems showed how large was the percentage of persons who had old-healed tubercle, while vital statistics proved that the death-rate was on the decline. Some asserted that Nature alone would operate in controlling the disease, but philanthropic motives, economic considerations, and self-interest alike pointed against this view. Dr. Walker then recounted the history of an attempt he had made to establish a municipal sanatorium at Aberdeen, which had been frustrated through the issue of the Circular of the Local Government Board. He criticised some of the provisions of this circular, and urged that an amending Act was urgently wanted to deal with the special features of phthisis. He urged that the State ought only to control the disease in so far as it is infectious, and is not suited to undertake curative treatment. In the course of his attempt to establish a sanatorium he had made investigations concerning all the sanatoria for the working classes in existence in Great Britain. Apparently, there were only some 10,000 beds in all available, which was very far below the number of persons who were suffering from the disease. The sanatoria derived their incomes from several sources—from charitable funds, from paying patients, from friendly societies, from rating bodies, and also from working men. He had been surprised and pleased to hear that in some institutions a very large part of the funds was drawn from regular small subscriptions of the class for whom the benefits were destined. The average cost per bed was, as a rule, far too high. In some sanatoria it worked out at £300, which was folly. It was absolutely necessary that no superfluous decoration or expense of any kind should be incurred if sanatoria treatment on a large scale were ever to be provided. The same applied to the cost of maintenance, which averaged about 30s. per week. From a comparison with asylums, he was convinced that it ought to be possible to keep the cost per patient per week down to about 16s. As showing that the results of sanatorium treatment were such as to justify economically its adoption, he pointed to the action of the German insurance companies, which found it cheaper to build sanatoria and cure cases of phthisis among workmen than to pay sick wages and death compensation. In conclusion, Dr. Walker showed designs for a model sanatorium, which combined efficiency and economy, and could be built at a cost of £50 per bed.

Dr. **Lawson** and Dr. **Caverhill** discussed Dr. Walker's paper.

Dr. **Peel Ritchie** read a paper on "Observations on the Use of Inoculations of Bacterial Suspensions," an abstract of which will be found on page 345 of present issue.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Meeting held Thursday, March 12th, 1908.

The President, Mr. R. Marcus Gunn, F.R.C.S., in the Chair.

The following cases were shown:—

Mr. E. E. **Henderson**:—An orbital case, for diagnosis.

Mr. G. H. **Goldsmith**:—A case of retinitis.

Mr. **Arnold Lawson**:—A case of (?) albuminuric retinitis in a child, and a case of (?) Parinaud's conjunctivitis.

Mr. A. H. **Thompson**:—Punctiform remains of pupillary membrane, both eyes.

Dr. J. F. **Cunningham**:—Unusual form of choroido-retinitis.

The meeting then resumed the discussion on Mr. Leslie Paton's paper read at the last meeting on

OPTIC NEURITIS IN CEREBRAL TUMOUR.

Mr. **Paton** first modified his paper in respect of some of the percentages, sub-dividing them into more convenient classes. He also stated that since reading the paper he had been through the records of 60 additional cases, which bore out the conclusions he had formed on those already published.

Mr. **Herbert Parsons** said the paper was essentially statistical, and statistics did not lend themselves well to discussion: the only part open to debate was the conclusions which the author had formed on the figures. The records of the cases were of great value, because the ophthalmoscopic appearances were observed by the President. There was a distinct apparent discrepancy between the details in this series and those previously published by others. A recent series by Uhthoff, of Breslau, more nearly coincided with those of Edmunds and Lawford than with Paton's. Mr. Parsons insisted on the importance of not only recording the amount of swelling of the disc, but the stage at which it was observed. He was not in agreement with Mr. Paton's explanation of sub-cortical and pontine tumours in regard to vascularity. He did not regard the star at the macula as a mere result of the violence of the neuritis; there were cases equally violent in which no star was present. The latter he had seen more commonly in children than in adults. He considered that suggestions as to the cause of optic neuritis should be omitted from the discussion, as it did not really arise out of the paper.

Sir **VICTOR HORSLEY**, speaking as a visitor who had not heard the paper, but had an opportunity of looking it through, said the contribution was really founded on records of his own cases, and yet he was diametrically opposed to one of its most important conclusions. He protested against Mr. Paton's conclusion going forth under the ægis of that great Society as the one justified by the records of the Queen Square cases. He, Sir Victor, had taught for years, and had supported it by operative proof, that one was justified in regarding the homolaterality of the lesion as a point of clinical value. Every case must be dealt with on its merits, and he thought the difference of opinion between Mr. Paton and himself was due to the treachery of clinical statistics. He had long taught that it was essential to study the neuritis by the character of the changes in the disc, not the mere swelling. It was necessary to know whether it was an exudate, and indeed the minutest details of it. He had often seen a macular fan entirely disappear after the removal of a cerebral tumour. One point, which was learned from the Queen Square cases 20 years ago, but which did not find a place in the paper, was the question of pressure. Free opening of the dura mater would cause subsidence of the neuritis. The records contained very much information on that point, and he hoped Mr. Paton would be able to include it in his paper.

Sir **WILLIAM GOWERS** sent a communication, supporting some of Sir Victor Horsley's criticisms.

Dr. **BEEVOR** agreed with Sir Victor Horsley's remarks concerning the age of the neuritis. In 50 cases of cerebral tumour of all kinds which he investigated for his Lettsomian lectures last year, the optic neuritis was most severe on the same side as the tumour.

Dr. **FARQUHAR BUZZARD** complained that Sir Victor Horsley had not brought forward figures to support his view on homolaterality, valuable though his opinion was. The number or proportion of cases in which the neuritis occurred on the same side was not great enough to make it diagnostically important. Placing too much stress on the doctrine might lead to serious error.

The **PRESIDENT** thought the truth in the matter lay between the views of Mr. Paton and Sir Victor Horsley, in the way mentioned by Dr. Farquhar Buzzard.

Mr. **PATON** replied, quoting cases from his paper in confirmation of his previous contention.

Dr. **THOMSON HENDERSON** (Nottingham) gave a lantern demonstration on the venous connections of Schlemm's canal. He said the channels of the aqueous outflow were: Schlemm's canal, the suprachoroidal space, the iris. The last was an absorbing surface only because of its crypts. His object was to show the close venous connection beween those three channels. The vascular supply of the ciliary body was derived from the arteriosus iridis major, formed by the two long posterior ciliary arteries, reinforced by the eight anterior ciliary arteries, two from each rectus. The whole of the venous blood was returned *viâ* the venæ vorticosæ, except the small area drained by the anterior ciliary veins. A study of a large number of series of consecutive radial sections brought out the following points. In each mm. of the scleral circumference (42 sections equal 1 mm.) there was never less than one anterior perforating scleral vessel, frequently two, and occasionally three. There was free anastomosis among the vessels. Each perforating vessel sent or received an efferent branch from Schlemm's canal. He had not been able to find a perforating scleral vessel not connected with Schlemm's canal. Therefore, all those vessels were veins, and the so-called circulus arteriosus iridis major was a sinus venosus iridis. Schlemm's canal was nothing more than an offshoot of the iris veins. Before perforating the sclera, the iris veins were in free communication with the ciliary veins and radicals of the venæ vorticosæ. In chronic glaucoma, when adhesions of the iris root had been long enough established, serial sections showed new-formed vessels perforating the pectinate ligament, and connecting directly the iris veins with Schlemm's canal. This bore greatly on glaucoma and its treatment by iridectomy, as the success of the latter depended on the iris being an absorbing surface only by virtue of its crypts. Its effect was that of a large crypt occupying three sides of a square, for in a healthy iris the cut surfaces forming the base and pillars of the coloboma never healed. Cicatrisation was a protective process following as a result of the reaction of the cells of a tissue to irritation or altered condition of life. A successful iridectomy left the tissue cells bathed in aqueous, so that no stimulus was imparted to them to cause the formation of a dense protective layer. The cut iris tissue thus remained unaltered, and so presented a large raw surface, by means of which the aqueous could readily drain away, provided (a very important point) the operation were done before atrophy and damage to the iris structure had proceeded too far.

CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, MARCH 19TH, 1908.

Dr. CHAMPNEYS in the Chair.

THERE were also present Dr. Stanley Atkinson, Mrs. Latter, Miss Paget, Mr. Ward Cousins, Mr. Parker Young and Miss Wilson.

After the minutes of the last meeting had been signed, it was announced from the chair that Mr. Ward Cousins had been re-elected to represent the Royal College of Surgeons, and Mr. Parker Young to represent the Society of Apothecaries. Letters were read from the Under-Secretary of State for the Home Department, informing the Board that the Chief Constables of Counties and Boroughs, and the Commissioners of Police in London had been requested to report convictions of midwives direct to the Board; and from the Clerk of the Council stating that arrangements had been made by the Treasury for the supply and distribution of copies of the Midwives Roll to the coroners of England and Wales.

The following resolution, proposed by Mr. **WARD COUSINS**, and seconded by Dr. **STANLEY ATKINSON**, was passed :—

"That as no arrangement for the payment of fees to medical men summoned to assist certified midwives has been made satisfactory to the medical practitioners and certified midwives of the country, the time has arrived for the Board to reconsider the question, with special reference to the efficient operation of the Midwives Act, 1902."

Some discussion followed, both Mr. **WARD COUSINS** and Mr. **PARKER YOUNG** asserting that the question had not been seriously dealt with either by the Central Midwives Board or the Government; and that the recommendation of the Local Government Board to the Guardians empowering them to pay fees to medical men called in by midwives, "if they thought fit," was not effective or satisfactory. They considered that the Lord President of the Privy Council and the President of the Local Government Board should be asked to receive a deputation of the Central Midwives Board, which would proceed to explain the case to them, making clear the impossibility of the efficient working of the Act under present conditions.

The **CHAIRMAN** thought the Board ought to be grateful to the Local Government Board for its recommendation to the Guardians, which was the first step in the right direction. He maintained that the Central Midwives Board had concerned itself very much in the matter, and made several attempts towards removal of the difficulty.

Dr. **STANLEY ATKINSON** urged that before any steps were taken with regard to a deputation to the Lord President, it should be ascertained either by a question in the House or by the Secretary how far the Boards of Guardians throughout the country had adopted the recommendation of the Local Government Board.

Another suggestion was made by Mr. **WARD COUSINS** to the effect that a scale of payment to medical men called in by midwives should be drawn up by the

Board. It was agreed that the matter be referred to the Standing Committee.

On the motion of Mr. **PARKER YOUNG**, the Board agreed to rescind its resolution of December 19th, 1907, refusing the application of Dr. W. Colquhoun, of Govan Road, Glasgow, for approval as a teacher of pupil midwives, and that his name be added to the list of recognised teachers.

In the report of the Standing Committee, the question of making Plymouth a centre for examinations of the Board was dealt with. At present the number of candidates is insufficient. When not less than 20 can be guaranteed, the Board will re-consider the matter.

A letter was read from the Registrar of the General Medical Council in reference to the communication made to it by the Board with reference to Dr. Stevens, late Master of the Coombe Hospital, Dublin, stating that the Council does not propose to take any steps in the matter.

In reply to a letter from Dr. H. Handford, C.M.O. for Notts, it was agreed that Dr. Handford be informed that the case of a midwife suffering from septic ulcers or kindred complaints appears to fall within the terms of Rules E., 1 and 5, or might be dealt with by the Local Sanitary Authority under the Public Health Acts.

A resolution was passed that the Coombe Hospital, Dublin, be reinstated as an approved training school, and the **CHAIRMAN** remarked that the Board was quite satisfied with the straightforward manner in which the Governors of that hospital had dealt with the matter.

Referring to the proposed scheme for the training and supply of midwives discussed at the last meeting, when the Act shall come into full force, it was resolved to forward a copy of the following to the Privy Council:—

(1) That midwives (who are "a necessity") will be unable to make a living in many localities without extraneous aid.

(2) That such localities are very often exactly those in which their presence is most necessary from the poverty and (in some cases) the sparseness of the population.

(3) That voluntary contributions cannot be relied upon to supply the whole of the necessary financial aid.

(4) That for this purpose a Government grant is a necessity.

(5) That, if such a grant were provided, the Board thinks that a representative Council of competent persons should be appointed to administer the fund thus constituted.

Eight more midwives (*bonâ fides*) were removed from the Roll at their own request. Applications for approval as teachers were granted to A. Cambell, M.B., and Mary E. H. Morris, M.B.

In the Secretary's report of the February examination, a remarkable difference in percentage of failures was commented upon. The percentages were as follows:—London, 15 per cent.; Birmingham, 6 per cent.; Bristol, 13.6 per cent.; Newcastle, 18.4 per cent.; Manchester, 33 per cent. It was agreed that a visit of inspection should be paid to Manchester to inquire into the reason.

The next general meeting will be held on April 9th, and the Board will sit to hear the penal cases on March 26th and 27th.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD MARCH 6TH, 1908.

The President, Mr. RICHARD LAKE, F.R.C.S., in the Chair.

DR. ANDREW WYLIE read a paper on

FOUL BREATH: ITS CAUSES, PATHOLOGY AND TREATMENT.

He said fœtor of the breath is either purely subjective, entirely objective, or both. There are several different kinds of fœtor, such as the putrefactive, the sulphuretted hydrogen, the garlic, the sweetish, and the toxic types. Fœtor is classified according to the different regions responsible for its source: as diseases of the nose and the accessory sinuses, nasal obstruction and growths and naso-pharyngeal diseases, imperfect deglutition and carelessness in oral and dental hygiene, affections of the tongue and gums, caries of the teeth and imperfect dentures, diseases of the follicles of the tonsils, tubercular, syphilitic and malignant diseases of any part of the nose, pharynx or larynx; if cartilage or bone is involved, suppuration of the middle ear, bronchiectasis and abscesses of the lung, foreign bodies in any part of the upper air passages, gastro-intestinal diseases, and in paralytic patients. Fœtid breath is found more or less in spirit and beer drinkers, in smokers, in those who take certain drugs, and in those who follow certain occupations. Bacteria are the cause of the trouble, and the treatment is to find the cause and remove it, or at least reduce the activity of the bacteria.

Mr. W. H. BOWEN read a paper on

PNEUMOCOCCAL OTITIS MEDIA.

He stated his opinion that the pneumococcus was the organism usually causing acute otitis media at any age. The occurrence of otitis during epidemic diseases was not considered. Special attention was called to the onset of otitis media after operation on the nose and nasopharynx, and their etiology carefully considered. The sponging over the face with cold water was strongly condemned, and the importance of avoiding draughts and keeping the patients warm emphasised. The otorrhea of babies up to 18 months old was considered, and the comforter looked upon as the strong etiological factor, so much so that the speaker labelled them "Comforter Otitis Media." They were pneumococcal, and should be treated by cleansing the mouth in addition to local treatment to the ear. The paper finished with a consideration of the signs and symptoms of acute infection of the mastoid antrum and cells, which was practically always due to the pneumococcus.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 22nd, 1908.

TREATMENT OF COXALGIA.

PROF. CALOT, of Berck-sur-Mer, gave a very interesting clinical lecture at one of the Paris hospitals, and reproduced by the *Journal des Praticiens*, of which the following is an extended *resumé*:—

Although I am here to speak to you on the treatment of coxalgia, I must say a few words as regards the diagnosis of the disease, which you will be called on, in your general practice, to treat. Where the affection is well established the diagnosis is easy, but at its *début* it is not always so easy. However, if you bear in mind the following points you will not encounter much trouble:—

(1) Coxalgia should be suspected each time that a patient suffers, without apparent cause, from lameness or pain in the hip or knee.

(2) If examination of the hip reveals pain on pressure over the head of the femur, which is found, as you know, in the inguinal region about one-quarter of an inch from the artery, and a more or less limitation in the movement of abduction, coxo-femoral arthritis may be affirmed.

(3) If there exists, besides, a lengthening of the limb, this arthritis is tuberculous, and constitutes true coxalgia.

Once the diagnosis firmly established, the treatment, both general and local, will be applied.

Of the former it is not necessary to say anything, the malady being tuberculous, the general treatment will be prescribed accordingly.

As to the local treatment it consists in rest in the horizontal position and immobility of the articulation. This immobility is obtained by *continued extension* for private patients who can be closely watched, and a *plaster apparatus* for hospital patients, or those belonging to the poorer classes.

Such is the constant treatment, rest and immobility, of every form of coxalgia.

But complications may appear that require special treatment. They are three in number: *deviation, abscess, fistula.*

If a deviation exists you will correct it, not suddenly, but gently and slowly to avoid danger of general infection. Correction can be obtained by increasing the tension 10 or 20 lb., or by applying the plaster splints every fifteen or twenty days. Chloroform is not necessary.

If an *abscess* appears, it will be tapped, but *never* opened with a bistoury, nor should it be allowed to open spontaneously. Once the abscess is tapped a modifying liquid should be injected.

If the patient comes to you with a fistula, you will dress it antiseptically and no more. Neither resection nor curettage should be permitted.

To resume, the classical treatment of coxalgia amounts as follows:—Make a plaster apparatus, correct a deviation, tap an abscess, dress a fistula.

This treatment is continued until the patient feels no more pain on pressure of the head of the femur. However, if, clinically speaking, the patient is cured, anatomically, he is not, consequently I would advise you to wait four or six months longer before allowing him to get up and walk. At the end of that time he may begin to move about, either alone or by the aid of a celluloid support, in private practice, or one of plaster for hospital patients. This support will be worn as long as the limb has a tendency to deviate.

Such is the whole treatment which, as has been seen, is entirely *medical* from beginning to end.

As to the results, they must be studied as regards the cure of the patient and the nature of the cure itself.

In the first place, the treatment saves the life of the patient, which was, some twenty years ago, so frequently sacrificed, so that Gosselin used to say, "Coxalgic patients generally die." And why did they die then, whereas now they live? Because formerly abscesses were freely opened as well as the tuberculous joint. But to-day intelligent surgeons content themselves, in the treatment of coxalgia, with accepting the *rôle* of the physician.

As to the quality of the cure, it is not sometimes very brilliant where the patient is condemned to limp all his life. As a general rule, coxalgia requires from three to four years to get well—seldom less; in some benign forms one or two years, but frequently more.

I am going to show you now the manner in which patients get well of their coxalgia, for I have invited to come before you about thirty of my old patients living in Paris, whom I treated as I have just explained to you. As you see, there are a certain number, about a fourth, who walk very well, without a limp; about as many more walk well, but with a slight claudication; while the remainder limp considerably.

Are you satisfied with these results? I confess that I am not. It is true that it is thus that coxalgia is cured in general; but I cannot accept with equanimity such an incomplete cure.

It is for this reason that, for several years I have been studying the means of correcting, if possible, this claudication, which, the sombre point in the prognosis of coxalgia, is due to the destruction of the articular extremity. The classical treatment saves the life of the patient, but not the head of his femur. If we want to cure him completely without limping, we must find something better. The cause of the mischief is due to tuberculous fungosities which, first limited to the articulation end by penetrating the bone, soften and dissolve it. The fungus, consequently, must be attacked before it succeeds in destroying the bone, and, provided that the malady is recognised in time, that can be done by the inoffensive and efficacious method of early injection into the articulation of a mixture of olive oil, iodoform, creosote and ether:—

Olive oil, } āā 1½ oz.
Ether, }
Creosote, ½ dr.
Iodoform, 1 dr.

This treatment may be employed within the first few weeks, or even three or four months, after the disease has been clinically confirmed, since as yet the bone is neither destroyed nor softened to any appreciable extent. Placed in contact with the fungosities, the liquid provokes sclerosis of the morbid tissues or dissolves them completely, but from 7 to 10 injections are necessary to arrive at this result. (Here M. Calot presented several children radically cured; neither lameness nor shortening could be detected.)

The technical difficulties of these injections might discourage you at first, as the access to the articulation of the hip is not very easy. However, if you will bear in mind the two landmarks I give you, you will have but little difficulty in penetrating the capsule of the joint. The first is an horizontal line passing through the spines of the pubis; the second the femoral artery as it emerges under Poupart's ligament.

You will employ a Collin's needle, No. 2, or a fine trocar like the one I use, 4 in. in length, and insert it 1¼ in. below the horizontal line, and ¾ in. outside the artery.

In children from nine to twelve years of age the distances would be 1 in. and ½ in. respectively. The instrument should be inserted directly from before backwards, until the bone is felt—that is to say, to a depth of 2 in. At that moment the limb is slightly flexed, abducted, and rotated externally to facilitate the penetration of the liquid. The canula is held in contact with the bone with the left hand, while the trocar is withdrawn, and the syringe containing the solution adapted to the canula. When the injection is terminated, a plug of cotton is placed over the little wound, and the limb is returned very gently to its normal position. The injections are repeated once a week, until nine or ten are given. At the end of this period (two months) compression of the articulation by means of cotton wadding, with continued extension or plaster apparatus, is applied during two or three months. But four or five months more are necessary before the patient can be allowed to get up, and at that moment he is cured.

Consequently, by this method coxalgia can be completely cured within a year, whereas under the old treatment, three or four years were necessary, and even then claudication was the rule.

GERMANY.

Berlin, March 22nd, 1908.

AT the Medical Society Hr. Fleischmann gave an address on the

SERUM DIAGNOSIS OF SYPHILIS.

The essentials of Wassermann's serum diagnosis of syphilis were the following:—The combination of a substance with its anti-body had the property of combining with its complement; by this the blood corpuscles were dissolved, hæmolysis took place, which did not do so when the complement did not enter into combination. This was first done with the liver of children suffering from hereditary syphilis, which showed itself to be peculiarly antigen. Doubts arose as to the specificity of this body, when it appeared that the same reaction took place with extracts of non-syphilitic livers. Endeavours were made to isolate the active principle of the liver, and it was found that an alcoholic extract of liver was suitable for the reaction; from this it was believed that the conclusion might be drawn that lecithin was the essential constituent that formed the basis of the reaction, and as a matter of fact it was shown that an emulsion of lecithin did combine the complements. For practical purposes, however, the organ extracts proved more suitable. The speaker then tried cholesterine, vaseline, glycogen, kaolin, and mastic emulsion, and determined that the three latter did not give any complement formation.

The result of investigations hitherto was that a material was met with in many syphilitics that formed complements in combination with organ extracts and lipoid substances, and did not do so in the normal individual.

The speaker had examined a total of 230 cases, amongst them 38 control cases, the men being healthy, and in these the result was always negative. Amongst the remaining 192 were 160 who were undoubtedly syphilitic, and of these 117 gave positive results;

89 were certainly syphilitic with manifest symptoms, and of these 83 gave positive results, the other 6 were old cases that had been treated several times.

Those who were certainly syphilitic, but without symptoms, were 64, and 33 of these gave a positive reaction. The positive reaction here showed that the cases were still uncured, and that treatment had still to be continued. On the other hand, however, the absence of the reaction was not a proof that recovery had taken place, as experience had shown that the reaction might become positive again even when the symptoms had disappeared.

Five primary sores gave a positive reaction. Of 18 tabetics 16 showed a history of syphilis, and 13 gave a positive reaction; 32 cases in which there was a suspicion of syphilis showed a positive reaction 16 times.

The speaker concluded that further investigations should be made. When a case showed a positive reaction, it was proof that syphilis was still present, but when the result was a negative one no conclusions could be drawn at all.

Hr. Blaschko, in conjunction with J. Citron, had examined 400 cases. All cases undoubtedly non-syphilitic gave a negative reaction. In doubtful cases the result was sometimes positive, and this was evidence that syphilis was present, but no conclusions could be drawn from a negative reaction.

In cases in which the primary sore was still present the reaction was positive in 90 per cent. of the cases; in the first years of the disease so long as symptoms were present, the reaction was present in 98 per cent., but in latent cases in only 80 per cent. In late cases with symptoms it was present in 91 per cent., without symptoms in 57 per cent.

The reaction always occurred before the roseola, if it was absent when there was a primary sore, it might be from abortive treatment. It continued for years, and disappeared to show again when fresh symptoms made their appearance. In the later stages it could not be determined whether the reaction showed any connection with the original severity of the disease or the intensity of the treatment. He had made inquiries as to the statistics of life insurance societies, and had found that one-third of all those contracting the disease died of it in the end; but in this estimation all those diseases were included that were not unconditionally separated from syphilis. Another calculation showed that syphilitics had a mortality of 68 per cent., the majority of them dying from diseases of the system. For practical purposes it did not yet appear that the test was of any practical value; it did not show that the disease was still uncured, and that the patient must not marry.

Hr. Citron showed the reaction of Klausner, of Prague, which depended on the fact that when syphilitic serum was added to distilled water a deposit took place in the course of 15 minutes. This consisted of globulines, which in syphilis as well as in some other infectious diseases, not infrequently increased in the blood.

AUSTRIA.

Vienna, March 22nd, 1908.

Epidermolysis Bullosa Hereditaria.

At the "Gesellschaft für Innere Medizin," Leiner exhibited a boy, æt. 10, with a peculiar dermatose condition which appeared to be hereditary from the family history. Any pressure on the skin produced large vesicles, no matter whether applied to the palms of the hands, the soles of the feet, or any other part of the body. According to the mother's report, these bullæ were observed the first week after birth on the hands and feet. Since that time the child has suffered more or less from the same eruption on different parts of the body. The nails are abnormally bent and frequently changed, particularly the second and third fingers of the left hand, which are very friable and greatly twisted. Therapeutics were of little use in such cases.

Diphtheritic Liver and Spleen.

Popper showed preparations of liver and spleen taken from a boy, æt. 11. Both of these organs were greatly atrophied and hardened. The cirrhosis was not due to either alcohol or syphilis, but presumably due to diphtheria, which the boy had two years ago. During the last year he vomited blood frequently, as well as passing it by the rectum. There was throughout icterus and oppressive anæmia, the red blood corpuscles not rising above 2,000,000. The thoracic organs were normal, but the abdomen contained fluid and was not tender on pressure. The hepatic dulness lay between the fourth and seventh ribs, which indicated atrophy. The lower extremities were greatly swollen. The diagnosis excluded both tuberculosis and syphilis, but could not deny hepatic cirrhosis with atrophy and extreme anæmia.

As the atrophy must be due to cirrhosis, Talma's operation was decided upon, without any relief. This operation was to relieve all cirrhotic troubles, as Talma's theory was that the liver cells are destroyed by the interstitial fibrous tissue cutting off the blood supply. He believed a co-lateral circulation would restore this morbid defect by connecting the circulation with the stomach, or, better, by entangling the peritoneum in a wound of the abdomen along with a section of the liver, with the hope of establishing a co-lateral circulation through the peritoneum. The boy only survived 4½ months after this operation.

The post-mortem revealed a liver 480 grammes in weight, or 17 oz., just about half the weight it should be at this age. The section showed the typical granular interstitial diffuse hepatitis, confirmed by the microscopic examination, and in the spleen a large infarct was present. As stated above, alcohol, syphilis and tubercle were carefully eliminated, which left nothing to rest on but the effect of the severe attack of diphtheria two years previously.

Sterilisers.

These apparatus are now legion, but Weiss is anxious to add another to the number. His has a funnel-shaped neck, into which a fitting of gauze and cotton is placed, which removes all gross material from the milk. The metal bottle holds a litre, and is covered with a kind of hard cork. For cooling it is placed in a mixture of 1 kilo. of ice, 100 grammes of salt and sal ammoniac. This will cool the milk from 7° to zero C. in 40 minutes, where it may remain nine hours without developing a single germ or producing any decomposition.

Neurath asked how we were to know when the vessel was nearly full? Genser wanted to know if the milk would not be frozen when wanted?

Weiss thought the person who bought the milk would know; and, for the freezing, it did no harm to the milk.

Cane Sugar in Urine.

Reuss reported the case of an infant with cane sugar in the urine, which, he said, was an uncommon circumstance, and did not appear in the literature of the subject. The lactose seems to be fermented or absorbed in a split or complete form. The split or decomposed form goes to make grape sugar and galactose in the organism, while the unsplit or complete lactose cannot be digested. The grape sugar may either be oxydised directly or polymerised into glycogen; but the pancreas plays a part in the digestion and assimilation of grape sugar which cannot, with any degree of accuracy, describe what gives rise to his hypothesis on the subject. Be this as it may, galactose and levulose or cane sugar are usually admitted to be turned into glycogen. This molecular transition is usually demonstrated by the glycogen found in the liver, which passes hence by the urinary tract.

Hitherto, lactosuria was not unknown, although undescribed by clinicians in pediatrics, but is usually found in combination with galactosuria, probably caused by gastric disturbance, without any morbid intermediary being present. It seems the milk sugar escapes the splitting process in the bowel probably for want of a ferment, though no proof is forthcoming, or the wall of the intestine may become so injured or changed as to allow the lactose to pass on unchanged. Galactosuria in severe cases will produce intoxication from an alimentary source alone, but the presumption is that there is a degenerative process going on in the liver, when the levulose may be found present also.

Chlorate of Potassium Poisoning.

Weichselbaum showed two preparations from this form of poisoning. One had taken 100 grammes, and died within 36 hours; the other 30 grammes, and died in 10 hours. Though the stomach had been washed out in both cases, a large quantity of the salt was found in the organ after death. The principal changes observed were a large quantity of methæmoglobin in the blood, found in the spleen, liver, kidneys, and marrow of bones. There were also thrombic masses of methæmoglobin found in the aorta, veins and capillaries. The spleen had a rupture in its capsule, the stomach hæmorrhagic infiltration at the pylorus, while ulcers and erosions were strewn over the mucous membrane of the organ.

Schrötter thought the intoxication was due to the anuria produced by the potassium chlorate, which should be carefully used on this account.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE MEDICAL EDUCATION OF WOMEN IN EDINBURGH.—For some years past a movement has been on foot among those who interest themselves in the Edinburgh School of Medicine for Women to obtain for the students further privileges from the University. At present the women are admitted to graduation, but their teaching is almost entirely in the hands of special extra-mural lecturers, and what many desire is to see the University thrown entirely open to women on the same footing as to men. The premises which the Women's Medical School at present occupy have recently been sold, and will soon cease to be available, so that the authorities have to face the rather difficult question of housing their students, and have thereby been provided with an appropriate opportunity of raising the whole question of the relation of women to the University teaching. The Court of the Association for the Medical Education of Women has been in communication with the Carnegie Trustees and with the University Court. The Trustees, it is understood, indicated their willingness to give asisstance, but the cost of providing for separate classes would be greater than the number of students justifies, so that, practically, the question resolves itself into whether or not the University will sanction mixed classes. The University Court declined to meet the Court of the Association and the Carnegie Trustees, on the ground that it was not impossible to continue the work of the School on the present lines. The annual meeting of the Association for the Medical Education of Women, which took place on Friday last, was largely attended, and much interest was taken in the proceedings. Sir Alexander Christison stated that what they now proposed to the University was to make arrangements for (1) the teaching of anatomy to women; (2) the admission of women to the classes for the preliminary scientific subjects; (3) the teaching of physiology; (4) as regards the remaining classes, that the University should admit women where the Professors are appointed under the new ordinances, and where the Professors are unwilling to teach mixed classes, should appoint special lecturers; or (5) while the University admit women to the science classes with anatomy and physiology, the remaining classes should, as in the past, be empowered to arrange with extra-mural lecturers for the teaching of the other professional subjects. It was also stated at the meeting that the Association had proposed an eligible site for the anatomical department to the University, and that Prof. Cunningham had undertaken, if that site were selected, to organise and supervise the teaching of women. At present the women students are allowed the use of the physiological laboratory for certain stated periods before each examination, and it is suggested that a further extension of this system might be tried. The numbers of women who qualify in medicine here are not very great. The following are some of the recent figures:—1900, 23; 1901, 10; 1902, 18; 1903, 18; 1904, 17; 1905, 11; 1906, 26; 1907, 20. The difficulties which the students feel most are, undoubtedly, in connection with the scientific and earlier classes. The disadvantages of a private school in comparison with the University are most keenly felt in the teaching of subjects such as chemistry, anatomy, and physiology, which depends so largely on expensive apparatus and material, and involves large outlay. On the other hand, so far as the final subjects are concerned, and especially as regards clinical teaching, the students have little to complain of. They have exactly the same facilities as the men, though, naturally, their choice of teachers is limited, so that as regards the final year it is doubtful whether they would be as much better off as they imagine, if they were admitted to the "hallowed portals" of the University.

LORD RECTORSHIP OF EDINBURGH UNIVERSITY.—The Right Hon. George Wyndham, P.C., has consented to stand as Unionist candidate, and the Right Hon. Winston Churchill, M.P., as Liberal candidate for the Lord Rectorship.

SIR HENRY LITTLEJOHN'S RESIGNATION.—Sir Henry Littlejohn's resignation has been formally tendered to the City of Edinburgh. Since 1854 he has been Surgeon to the Police, and since 1862 Medical Officer of Health; to few of her citizens, whether officials or private individuals, does Edinburgh owe more than to Sir Henry Littlejohn. Although he is now approaching his 84th birthday, few would imagine, looking to his alertship and bearng, that he was within 20 years of that age. He took his degree of M.D. in 1847, and in 1855 became a lecturer on medical jurisprudence in the Royal College of Surgeons. He continued lecturing to crowded class-rooms there until 1896, when he was elected successor to Sir Douglas Maclagan. This post he resigned in 1906, and was followed by his son, the present Professor—an appointment which was hailed with unanimous approval as the best choice possible. Sir Henry Littlejohn's work in the city has throughout all his term of office been of the greatest value. He was the guiding spirit in pulling down slums and driving open thoroughfares through them, which about the Sixties led to the practical abolition of typhus fever, which had previously been endemic. He introduced the Infectious Diseases Notification Act, and applied it to Edinburgh. The death-rate of the city has fallen from 26 per 1,000 to 14 per 1,000 during his term of office. Sir Henry Littlejohn has enjoyed a great reputation in medico-legal matters, and has figured as a witness in almost every important criminal trial of late years. About a year ago he was presented by his friends in legal and medcal circles with his portrait from the easel of Sir George Reid. It is difficult to think of Sir Henry Littlejohn as ceasing to play a part in the administration of sanitary affairs of Edinburgh, but that he has more than earned the right to rest now none who are acquainted with his strenuous activities will deny. His wide circle of friends unite in wishing him well on the occasion of his withdrawal from work, and very cordially hope that he may long enjoy a well-merited leisure in his retirement.

BELFAST.

HOSPITAL ABUSE.—A conjoint meeting of the Ulster Medical Society and the Ulster Branch of the British Medical Association was held in the Medical Institute, Belfast, on Thursday evening, February 20th, to which all medical practitioners in the district were invited by special circular to consider the question of hospital abuse. On the motion of Dr O'Neill, seconded by Dr. Darling (Lurgan), the chair was taken by Dr. John McCaw, President of the Ulster Medical Society. The discussion was opened by Dr. John Campbell, who dealt first with the causes, and secondly with the remedies, as he believed. The persons mainly responsible he considered to be the Governors of charitable institutions and the working classes who attended them. Three remedies had been suggested and tried:—(1) The patients might be questioned by the medical man who saw them at hospital: this he considered *infra dig.* and objectionable. (2) There might be a special inquiry officer attached to the institution. (3) Patients might be referred back to their own medical man for information. This last he believed to be the best plan of the three, but it necessitated the help of the general practitioner, and without his support it would not work. Mr. Andrew Fullerton, who was the original promoter of the meeting, divided those attending hospitals into four classes as he saw them:—(1) The necessitous poor; (2) the "border-lander"; (3) the unprincipled sponger; (4) the penny-a-week subscriber, who comes as a matter of right. The discussion was continued till a late hour, the following taking part:—Drs. O'Neill, Kevin, A. McConnell, Darling (Lurgan), St. George (Lisburn), Robert Campbell, A. B. Mitchell, Trimble, Killen, Burns, McKisack, Kirkhope, P. O'Connell, Fraser, Walton Browne, J. Simpson, Morrow, R. J. Johnstone, T. Davidson, Gaussen, and the President. Mr. Fullerton replied, and proposed two resolutions, which were passed:—(1) That a circular should be sent to all practitioners in Ulster, asking them to second the efforts of the medical staffs of the hospitals to prevent hospital abuse. (2) That a committee of general practitioners should be appointed to carry this out, to consist of the President, Drs. Elizabeth Bell, Burns, T. Davidson, Fraser, Kevin, Watson and Trimble, the last to act as convener.

BELFAST MATERNITY HOSPITAL.—The 114th annual meeting of this institution was held last week. The report showed that 378 cases had been admitted last year, and 306 children were born. Five deaths occurred among the intern cases, but all five were hopeless when admitted. The extern cases numbered 283, and there were no deaths. Sir Charles Brett, in seconding the adoption of the report, vigorously defended the newly-formed Women's Health Association from a very uncalled-for and injudicious attack made upon it a few days before by the City Coroner, Dr. Graham. The latter, at an inquest on a child, went out of his way to refer to the Association, which has just been founded, under the auspices of H.E. Lady Aberdeen and the Dowager Marchioness of Dufferin and Ava, with a lady doctor and the wife of a leading physician as honorary secretaries. He gave it as his opinion that it was pure hypocrisy for these ladies to try to teach poor mothers to bring up their children, as most knew well enough how to do it, and practical help was what was wanted. Medical men generally will agree with Sir Charles Brett that there is ample room for the Ladies' Health Association to work in Belfast, and that the ladies can be relied on to see that, where practical help is needed, the aid of one of the numerous societies giving such help will be called into the case.

ST. PATRICK'S DAY DINNER.—The annual dinner of past and present Queensmen was held in Queen's College on St. Patrick's Day, the chair being occupied by Professor Letts. Among other speakers, President Hamilton, Professor Symington, and Dr. A. B. Mitchell referred at some length to the University question. As the time of publication of Mr. Birrell's Bill approaches, the interest in it grows greater, and the belief gains ground that there is at least a better chance than on any previous occasion of a settlement being reached. Dissatisfaction with the Royal University is very general, and the number of Ulster men who wander off to Glasgow and Edinburgh in consequence of the unsettled state of Irish University affairs shows no signs of growing less. There is also a strong feeling among those more closely associated with the College that the Belfast school should be free to develop on its own lines, and not be tied to other schools whose environment is different and whose students are of a different character.

LETTERS TO THE EDITOR.

BRITISH MEDICAL ASSOCIATION—THE REFERENDUM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The welfare of the whole profession, if not closely bound up with, is at least very closely connected with, the welfare of the British Medical Association. The Association numbers over 20,000 members; it is the sole organised representative body through which the profession has the power to make its voice heard, its influence felt; it might be made a tremendous force in promotion of progress in every direction. By the behaviour of the members in the matter of the Referendum—the result of which is published to-day—it is, however, made quite evident that the vast majority care literally nothing at all for these objects, and are absolutely indifferent with regard to the constitution and government of the great Association to which they belong. The questions which the Referendum was to decide were vital; they were brought forward with the utmost energy; they were discussed in endless articles and in a voluminous correspondence in the *Journal;* they were forcibly presented before the notice of branches, divisions, and individual members, so that no one could be ignorant of the magnitude of the issues involved; and yet, when the 159 divisions within and without the United Kingdom are called upon to vote, the aggregate attendance of members at the meetings amounts to 1,978. The most astonishing indifference has been displayed in every direction, and especially in divisions where the keenest interest might have been expected. In Aberdeen, with 153 members, not one came forward to vote. In the Cambridge division, out of 140, only 14 attended; in the Liverpool Central, out of 66, only 9; and in the Manchester Central, out of 75, only 4. In the Metropolitan Marylebone division, with 589 members, only 12 voted; whilst in Birmingham, that centre of light and leading, out of 302 in the Central Division, only 20 took the trouble to vote; and these are fair samples of the whole. It is amazing, it is deplorable; it is to me inexplicable. Some few years ago I ventured to express the opinion in your pages that the Association seemed to be at that time in danger of falling into the position of a mere co-operative society for the publication of a cheap medical newspaper, albeit I pointed out that, whilst the *Journal* was being supplied to the members at a low price, it was being produced at an enormous cost, absorbing, as it did, the greater part of the Association's huge income. The almost complete apathy of the members in this matter of the Referendum goes to show that I was not far out in my estimation of the Association's real position. Until that position be fundamentally altered, and until the Association becomes able unquestionably to speak in the united voice of the great majority of members, the political power of the profession will remain at its present negligible quantity, and neither medical law reform nor any measure for improving the status of the profession, will have the remotest chance of success.

I am, Sir, yours truly,
AN OBSCURE PRACTITIONER.

March 21st, 1908.

HOSPITALS FOR THE LOWER MIDDLE CLASS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A line and a half in your present issue opens a question as to the need for the ventilation of which I have long been convinced. I refer to the entire absence of provision for the class known as the "lower middle" in the matter of hospital accommodation and advantages.

This class, heavily burdened with taxation, and with the necessity of considerable and constant effort to maintain appearances, is, of all, the most heavily handicapped in case of a sudden or prolonged drain upon resources in case of severe or urgent sickness by accident or disease.

The methods of the King's Hospital Fund prevent the admission of this class to general hospitals, or, indeed, to any supported by that Fund to any useful extent, though without the contributions of the same class it would find its income greatly diminished. The best medical and surgical skill, and unrivalled nursing, are at the command of the artisan class, and in chronic cases the parish infirmary falls but little short of the same standard, whilst the struggling schoolmaster or clerk or tradesman is practically debarred from both. Thirty years' experience in practice have proved the truth of the above statements in my own knowledge in scores of cases, and whilst I admit that the matter is not free from difficulty, there seems no real reason why some start should not be made in the direction indicated. Such an institution, once the capital expenditure was covered, might be made largely self-supporting, and in the face of the abundant eleemosynary provision for the artisan class, the latter would have no valid ground of complaint if a portion of the funds subscribed for its benefit were permitted to return to its source in the manner suggested.

Personally, I should be extremely willing to assist in starting some scheme on the lines indicated.

I am, Sir, yours truly,
March 18th, 1908. EDWD. C. BOUSFIELD.

OBITUARY.

DAVID RAMSAY MILLER, M.B., C.M.GLASG.

WE regret to announce that Dr. D. R. Miller died on March 12th at the early age of 35. Dr. Miller was the only son of Mr. William Miller, of Glasgow. After taking his degree in medicine and surgery at Glasgow University, he made two voyages to Bombay as a ship's surgeon. He then commenced practice at Scunthorpe, in Lincolnshire, where he remained twelve years. A few months ago he went to reside in Chesterfield Road, Sheffield, but unfortunately his health gave way, following an attack of influenza. He leaves a widow, but no children.

SURGEON-MAJOR BREW.

WE regret to record the death of Surgeon-Major Brew, which occurred at Bray, Co. Wicklow, during the past week. Dr. Brew was for many years the Medical Officer of Health for Bray, and Dispensary Medical Officer for a quarter of a century. He was also Medical Officer to the Royal Irish Constabulary in the district. The crowds of poor who attended his funeral bore an eloquent testimony to the regard in which he was held.

DR. F. W. STAUNTON.

THE many friends of Dr. F. W. Staunton, of Waterford, heard with feelings of deep grief the news of the tragedy which deprived him of his life just five weeks after his marriage. Dr. Staunton, who was a keen follower of hounds, received a severe fall whilst riding in the Waterford Hunt Point-to-Point races on March 12th, and dislocated his thigh. He was conveyed to his home and attended by Dr. Morrissey, of Waterford, but the following day his condition became much worse, and he developed symptoms pointing to acute peritonitis. Mr. Heuston, of Dublin, was brought to see him, and decided to operate, but without avail, and Dr. Staunton died on the 18th inst. Whilst Dr. Staunton was still a student, he, on several occasions, was threatened with peritonitis, the presumed result of injuries received whilst playing football, and on one occasion had to be operated upon for what was then termed perityphlitis. Doubtless, his untimely death was due to a lighting up of his former trouble. Shortly after he became qualified, Dr. Staunton was appointed to Portlaw Dispensary District, and this post he held for several years. He then moved to Waterford, where he practised until his death. He held the posts of Surgeon to the Waterford Infirmary and Medical Officer to Waterford Prison. The deepest sympathy has been expressed with his bride in her bereavement.

WILLIAM WOOD, M.R.C.S., L.S.A.

WE regret to announce the death of Dr. William Wood, of Middleton-on-the-Wolds, which took place on March 13th. Dr. Wood was one of the oldest practitioners in the North of England, having been qualified in 1857. He held many local appointments, and was greatly esteemed for his skill and kindness.

A NORTHERN Counties' branch of the Incorporated Institute of Hygiene was inaugurated at Newcastle-on-Tyne on Monday last by Prof. Sims Woodhead, M.D., F.R.C.P., who was supported by Sir Isambard Owen, Prof. Thos. Oliver, Prof. Geo. Murray, Mr. Geo. Lunn, J.P., Mr. Johnstone Wallace, Dr. Thresh (Chairman of the Council), and others. Sir Geo. Hare Philipson, M.A., M.D., D.C.L., LL.D., F.R.C.P., occupied the chair.

REVIEWS OF BOOKS.

INTERNATIONAL CLINICS. (a)

NUMEROUS interesting clinical and scientific papers are included in the present volume of this popular quarterly. Prof. Calmette contributes a short paper on his now celebrated Ophthalmo-reaction. Dr. Henry now writes on Meltzer's treatment of tetanus by intraspinal injections of magnesium sulphate. The value of fresh blood serum in disease is discussed by Weil, and a useful summary of what may be expected from the X-ray treatment of leukæmia is written by Warthin. Mr. Connell's paper on Pseudo-myxoma of the Peritoneum, secondary to cystic disease of the appendix, is useful and suggestive, and Lumoyez's discussion of the use of thiosinamine and its derivative fibrolysin in otosclerosis is of more than special interest, as it gives fresh proof of the value of this drug in causing absorption of connective tissue. Numerous other papers are included, but space forbids us to mention them in name. It is sufficient to state that material of interest to those engaged in every branch of medical work is provided.

BIOGRAPHY OF THOMAS SKINNER. (b)

THE name of Thomas Skinner is, we have no doubt, familiar to many medical men who have no knowledge of the man further than that he has given his name to an apparatus for the administration of chloroform. This ignorance is no doubt due to the fact that during the last thirty years of his life Skinner deserted the practice of legitimate medicine for what most of us believe to be the errors of homœopathy. Born in 1825 of Scotch parents, Skinner was educated in Edinburgh, and started work in a business house in that city. At twenty-four years of age he deserted the office stool for the study of medicine in the University of Edinburgh and the School of the Royal College of Surgeons of that city. He obtained the Licentiateship of the latter corporation in the year 1853, having obtained the gold medal in Sir James Simpson's class of obstetrics in the University. Skinner then became private assistant to Sir James Simpson, in which position he continued for two years. It was while working at this time in association with Simpson that Skinner described the chloroform mask and drop bottle to which his name has been ever since attached. Leaving Edinburgh in 1859, Skinner started practice in Liverpool, and was appointed Obstetric Physician to the Liverpool Lying-in Hospital. His knowledge and skill as an obstetrician soon gained for him a large practice, but his health broke down under the strain, and he was obliged for some years to travel in search of health. He is stated to have suffered from acid dyspepsia, constipation and sleeplessness. For these symptoms he was treated by a variety of drugs without any benefit, and eventually, in 1873, put himself under the care of Dr. Berridge, a homœopathic practitioner. According to his own statement, he appears to have been cured of all his troubles by a single dose of sulphur prescribed in "the mm potency." As a result of this success, Skinner devoted himself to the study of the works of Hahnemann, and two years later he resigned his medical appointments and started practice afresh as a homœopath. In this practice he attained considerable eminence both in Liverpool and London, to which city he moved in the year 1881.

This much we gather from the biographical sketch before us, and we could wish that our author had devoted more space to the description of Skinner as a man, and less to the explanation of the principles which he adopted in his later life. The work, however, appears to be written for homœopaths, and to them, no doubt, the various opinions which Skinner adopted and combated will be interesting, for he was a leader in their ranks. To us who differ from his views these disputes have little interest, but we cannot withhold our admiration for his honesty and for the ability with which he supported his mistaken views.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Treatment of Tetanus by Intraspinal Injections of Magnesium Sulphate.—This treatment was first suggested by Meltzer, but has hitherto been used in too few cases to allow any conclusions regarding its value to be formed. From the symptomatic point of view, it is undoubtedly satisfactory, relieving the patient from tonic and clonic spasm, and permitting prolonged sleep. When employed on monkeys inoculated with tetanus, it seemed to be of great value, but too large doses caused sensory and motor paralysis, followed by death from general respiratory failure. Henry now reports four clinical cases treated by the method (*International Clinics*, Vol. IV., 17th Series, page 1). In the first case 9 c.c. in all of a 25 per cent. magnesium sulphate solution were injected by lumbar puncture. On the first injection of 3 c.c., relaxation occurred after 15 minutes, and the two subsequent injections were followed by even more rapid relaxation lasting for several hours. This case recovered, but the other three cases proved fatal. Cases II. and III. were samples of hyper-acute tetanus, but Case IV. was mild, and the writer fears that the treatment may have been in part the cause of the fatal result. In this case there was very severe bronchorrhœa following the injections, and after the second and last the patient remained relaxed, dull and stupid, and finally died in coma. M.

Cholecystitis in Typhoid Carriers.—Simon (*Klin. Jahrbuch.*, Bd. XVII., p. 363) describes a case of chronic cholecystitis with pus in the distended gall-bladder, from which there resulted a chronic infection of the intestines with typhoid bacilli. Surgical cure followed an operation, but not a bacteriological cure, and the patient has continued to be a chronic typhoid carrier. Apparently she has been the cause of transmitting the disease to at least two other individuals. M.

The Ophthalmo-Reaction for Typhoid Fever.—Kraus and others have attempted to determine the value of Chantemesse's ophthalmo-reaction for typhoid fever (*Wiener. Klin. Woch.*, 1907, No. 43). Extracts from toxic typhoid cultures, from cultures of the colon bacillus, and from cultures of the paratyphoid bacillus B., produce no reaction, or at most the slightest redness, when introduced into the conjunctivæ of healthy persons. The same extracts cause an inflammatory reaction, for the most part limited to the conjunctiva of the lower eyelid, when introduced into the conjunctival sac of typhoid patients, but also unfortunately react on patients ill from other diseases. The writers conclude that the agglutination test is still the only exact and reliable method for the diagnosis of typhoid fever. M.

Sudden Death in Pleural Effusion due to Change of Position.—Dr. Calvert discusses the mechanical cause of sudden death in cases of pleural effusion from change of position (*Johns Hopkins Hosp. Bulletin*, February, 1908). He points out that the pressure exerted by an effusion upon the veins and the heart is a compound of two factors. The first of these may be called the constant pleural hydrostatic factor, and is the pressure with which fluid has been forced into the pleural cavity. The second is the variable factor, and is the hydrostatic pressure caused by gravity. This factor varies with the height of the column of fluid, and will therefore obviously vary with change of position. When the sum of the two factors is greater than the venous pressure, the veins must collapse, giving rise clinically to dyspnœa and irregular pulse, followed almost immediately by fatal syncope. Even though the syncope causes the resumption of the horizontal position, and consequently a fall in the total pleural pressure, it is seldom that the heart is capable of again beating under the renewed stimulus caused by the inflow of blood. Clinicians should, however, under these circumstances employ prolonged stimulation of the heart, and should turn the patient on the affected side, as experiments on animals have shown that good results may follow such measures. M.

The Persistence of Widal's Reaction after Typhoid Fever.—Louisson and French have investigated the above indicated subject in 135 cases, and have arrived at some valuable conclusions (*Guy's Hosp. Reports*, Vol. LXI., p. 235). They summarise these as follows: (1) In most cases the Widal reaction disappears rapidly after the typhoid fever. (2) In 7.5 per cent. of their cases the test remained positive for varying periods up to eight years. (3) The age of the patient at the time of the typhoid fever does not seem to influence the persistence or otherwise of the reaction. (4) The reaction is apparently more liable to persist in males than in females. (5) The presence of post-typhoidal suppuration increases the likelihood of this persistence. (6) The cause of persistence is not known in most cases, and it is only possible to determine by trial what patients will and what will not give a positive test. M.

Graves' Disease and Its Treatment.—Thomson (*Amer. Journ. of the Med. Sciences*, March, 1908) enters a plea for the non-operative treatment of this disease. He bases his views on the pathology and therapeutics of the disease, on clinical observation rather than on laboratory experiment, and justifies his treatment, and incidentally his pathology, by the results he has obtained in practice. He is satisfied that all the symptoms of the disease are due to a universally acting poison or toxæmia, that the disease is one that cannot be confounded with anything else, even though such characteristic symptoms as the exophthalmos and the goitre are absent, and, further, that this poison "causes no more tissue changes, except, indirectly, on nutrition, than does opium or aconite." Thomson believes that this poison is generated in the alimentary canal, and normally is neutralised in the thyroid gland, and excessive amounts of this poison excite the thyroid to over-action, and "thus often, but not always, lead to its hypertrophy." He explains the fact that the disease has been cured by partial removal of the thyroid by assuming that "due to a physiological affinity the thyroid may accumulate a store of enzime-like toxin brought to it by the circulation which may then act as a nidus for discharging the agent from time to time when the gland is stimulated by fresh supplies of the toxin derived from improper diet." The formation of this toxin in the intestine is associated with, or due to an inability of the organism to assimilate properly proteids, much as diabetes is associated with or due to an inability to assimilate the carbohydrate elements of diet. The treatment based on these views is partly dietetic and partly medicinal. The standard article of diet is milk which has been fermented or peptonised, and butchers' meat is never to be allowed. The patient may also use vegetables, most cereals, and some fruit; strawberries and uncooked apples are forbidden. As regards medicine, 30 grains of phosphate of sodium are to be taken at the beginning of each meal, and a blue pill or other mercurial laxative as a routine twice a week. At bedtime the patient is to take some intestinal antiseptic, such as naphthalene and sodium benzoate, or phenol bismuth and ammonium benzoate. The treatment must be extended over a long period, and Thomson states that if it is continued, good results will be obtained; but too early a return to a meat diet is always attended with a recurrence of the symptoms, often in an increased severity. K.

Specific Immunity and X-Ray Therapeutics.—Chane (*Amer. Journ. of the Med. Sciences*, March, 1908) has investigated the results of X-ray therapeutics in bacterial diseases by the estimation of the opsonic index for the specific bacterium involved. He finds that the opsonic index after X-ray treatment behaves in a manner quite similar to what it does during the treatment by bacterial vaccines. The correctness of these views he has demonstrated in a case of lupus, where the tuberculo-opsonic index was raised by X-ray treatment, and remained high till the patches of lupus had completely healed, after which time it gradually fell, in spite of the continued application of the rays. Chane concludes that X-ray treatment should be of sufficient intensity to set free in the tissues what is an equivalent to an autogenous vaccination, and that the duration of the exposure and the extent of the diseased tissue exposed should be so regulated as to induce either a small negative phase or none at all. The repetition of the exposures should also be regulated by the length of the negative phase. If the bacterium causing the disease is not known, then the treatment is still applicable, but must be regulated by analogy with those cases in which opsonic estimations can be made. K.

Pneumothorax in a Boy Two Years Old.—Huber (*Archives of Pediatrics*, February. 1908) reports the sudden occurrence of this condition in a boy of two years of age. The child, with the exception of an attack of measles and pneumonia during the first year of life, had been perfectly healthy until 14 days prior to his admission to hospital. He was then suddenly attacked with fever and vomiting, but appeared to recover, and was about again for nearly a week. He was then attacked with severe cough, vomiting, some fever, and considerable dyspnœa, but no cyanosis. On admission to hospital the signs of pneumothorax on the left side were quite evident. The child made a very satisfactory recovery without the intervention of any surgical treatment. Repeated examination of the sputum failed to demonstrate any evidence of tubercle bacilli, but the fluid in the thoracic cavity was not bacteriologically examined. K.

Pneumonia.—Thompson (*Amer. Journ. of the Med. Sciences*, January, 1908) relates his experience with an open-air treatment of pneumonia in the Bellevue and Presbyterian Hospitals, New York City. The treatment is carried out by placing the patient on a balcony, or at least at an open window, the air of the ward being more or less excluded by a screen. The balcony floors are of wooden slats, and sometimes it was so cold that the sputum froze in the cups. In alcoholic subjects it was found that much less stimulation was required, and it was often possible to do without it altogether. The open-air treatment is to be regarded as an adjunct to the measures usually employed, and the author concludes:—With this simple but effective armamentarium one may deal satisfactorily with the greatest number of the more serious cases of pneumonia; but it will be found that much of it, simple as it is, may be unnecessary if the patient has continuous access to fresh, free-blowing air. D.

Post-Delirious Alcoholic Stupor.—Stillman (*New York Med. Journ.*, January 25th, 1908) describes the peculiar stupor that sometimes follows alcoholic delirium. Pathologically, œdema of the meninges occurs with surprising regularity in these cases. However, inasmuch as considerable degrees of serous effusion of the meninges are found post-mortem in cases that during life have given no special symptoms, the writer believes that the causation of the œdema had probably better be looked for among the general conditions underlying the stupor. He reports a series of 98 cases, or about 1 per cent. of the total number of cases admitted to the alcoholic wards of the Bellevue Hospital. Approximately 80 per cent. died. Exhaustion was the cause of death in many cases. The constant features, in addition to the stupor, are muscular rigidity, stiff neck and hyperæsthesia. The temperature is very slightly elevated. There may be considerable difficulty in the differential diagnosis from tuberculous meningitis. Treatment consists of forced feeding combined with stimulation. Citrate of caffeine in 5 gr. doses is spoken of highly. D.

The Fibrolysin Treatment of Perigastric Adhesions.—Michael (*Berlin. Klin. Woch.*, December, 1907) reports two cases of severe perigastric adhesions which were much benefited by injections of fibrolysin. The first was a man, æt. 32, in whom severe gastric symptoms developed, due to adhesions about the stomach following a gastric ulcer. He was treated three distinct times for gastric ulcer, and operated on once without relief of symptoms. Great relief resulted from a course of fibrolysin injections, after which the patient was well enough to resume work. The second was a seamstress, æt. 26, who had been through several gastric ulcer "cures" without relief of distressing pain in the region of the stomach after eating. On entrance to hospital, a tumour near the pylorus was palpable. After 18 injections of fibrolysin, this tumour had disappeared, the symptoms were much improved, and the patient was able to resume work. The author used Merck's fibrolysin (thiosinamin sodium salicylate) in doses of 1.15 c.cm., injected into the abdominal wall in the region of the stomach. No untoward symptoms were noted. The article ends with a review of the few reported cases of adhesions in the gastro-intestinal tract treated by fibrolysin. D.

Amyl Nitrite in Tuberculous Hæmoptysis.—Braga (*Gazz. deg. Ospedali, Milan*, December, 1908) has used amyl nitrite 15 times in severe cases of hæmorrhage from tuberculous lungs, and each time has been impressed with the prompt action of the drug and its efficiency in these conditions. The hæmorrhage was arrested as if by magic, blood ceased to accumulate in the bronchial passages, and thus the evil effects of its decomposition were avoided. Five or six drops of amyl nitrite on a wad of cotton were inhaled, and the hæmorrhage ceased at once, and did not recur in the majority. The inhalations were repeated several times afterwards during the day. It proved effectual, even in cases in which no other measure had given relief. He supplemented the nitrite by the slower acting action of an enema of gelatin, to which calcium chloride had been added, with fluid extract of hydrastis internally. Since this technique has been adopted, no patient has succumbed to hæmoptysis, and whenever it appears it is speedily controlled. D.

MEDICAL NEWS IN BRIEF

International Medical Congress—Prize for Ophthalmology.

Prof. Emile Grosz, the Secretary-General, gives notice that the sixteenth International Medical Congress will be held at Buda-Pest from August 29th to September 4th, 1909, under the patronage of His Imperial and Royal Majesty Francis Joseph I. The work of the Congress is divided into 22 divisions, with a special sub-section of orthopædics attached to the section of surgery. The Royal Hungarian Minister of the Interior offers a prize of 1,000 crowns for the best essay on the Ætiology of Trachoma. All works, whether in manuscript or published for the first time in 1907 or 1908, will be eligible for competition provided they are in English, Hungarian, French or German. Essays are to be sent to the Minister of the Interior (Belügyministerium, Buda-Pest, Hungary) before December 31st, 1908. The jury will be appointed by the Minister of the Interior, and the verdict will be announced at the inaugural meeting of the Congress. The subscription to the Congress is 25 crowns (about £1 sterling), the wives and daughters of members paying 12½ crowns. The officials of the English National Committee are a President, Dr. F. W. Pavy, F.R.S., and two Honorary Secretaries, Dr. Clive Rivière and Mr. D'Arcy Power. The address of the Hon. Secretaries is 10A, Chandos Street, Cavendish Square, W.

West London Hospital Conversazione.

THE Duke of Abercorn held a reception at the Post-graduate College, West London Hospital, Hammersmith-road, last Thursday, on the occasion of the annual *conversazione* of the staff. The guests numbered over 200, and included Sir Havelock Charles, Sir Joseph Fayrer, Surgeon-General Charlton, many members of the medical services, and medical practitioners from al parts of the country. Mr. L. A. Bidwell, the Dean of the College, Dr. D. W. C. Hood, C.V.O., physician, Mr. C. B. Keetley, the senior surgeon, Mr. Percy Dunn, and Dr. J. Barry Ball were also present. During the evening the guests were afforded the opportunity of inspecting some valuable and interesting exhibits representing the latest medical and surgical appliances. Dr. G. C. Low exhibited some pathological specimens, microscopic sections, and apparatus from the pathological laboratory, while Dr. David Arthur gave an exhibition of X-rays, high frequency, and ultra-violet light, etc. A musical programme was provided by the London Concert Quartet.

Irish Medical Schools' and Graduates' Association.

ABOUT 200 ladies and gentlemen sat down to the annual festival dinner of this Association on Tuesday, March 17th, under the Presidency of Sir Charles MacDonagh Cuffe, K.C.B., at the Wharncliffe Rooms, Hotel Great Central. Amongst those present were the Right Hon. Sir Edward Carson, K.C., M.P., and Lady Carson, Dr. Windle, F.R.S., Insp.-Gen. W. H. Lloyd, Mr. and Mrs. Watson Cheyne, Messrs. Charles and Canny Ryall, Dr. J. T. Mason (Chairman of Council), Dr. Kenneth Fraser (Vice-Chairman of the Council), Dr. Michael Bulger (Hon. Treasurer), and the Hon. Secretaries (Dr. Wm. Douglas and Mr. G. W. Dawson). After the usual loyal toasts, Dr. Leonard Strong McManus proposed "Our Defenders" in a humorous though slightly pessimistic speech, the response being divided between Inspector-Gen. Lloyd, Col. Moorhead and Major Moyle O'Connor. Dr. H. MacNaughton-Jones next gave "Our Guests" in a patriotic and friendly discourse, in response to which came the speech of the evening from Sir Edward Carson, who so thoroughly held his audience that when he drew near to the end of his remarks and said he had spoken long enough, he was greeted by "No—go on," a very rare episode in after-dinner oratory. In answer to the same toast, Dr. Windle worthily kept up the reputation of the medical profession, not to be left far behind in oratory even by the law. "Ourselves" was proposed by Mr. R. G. Webster, and responded to by the President, who also had to respond to the toast of his own health, proposed by Dr. F. Mouillot. A very enjoyable, breezy evening, although the music, with the exception of Miss Muriel Warwood's violin solos, was hardly up to the mark.

Causes of Sleeping Sickness.

A MEETING of the African Society was held at the Royal United Service Institution last week, when Colonel David Bruce read a paper on "Sleeping Sickness." The chair was taken by Sir West Ridgeway, who recalled to the audience the fact that Colonel Bruce's achievement was the discovery of the germ of Malta fever. His great researches into the tsetse-fly disease were well known, especially in regard to sleeping sickness. Colonel Bruce said that sleeping sickness had been known on the West Coast of Africa ever since those parts were known, but it was looked upon more as a pathological curiosity than as a disease with a great power for evil. It was first discovered in Uganda in 1901, and the most common theory was that it was brought there by Emin Pasha's Soudanese soldiers. The proven facts were that sleeping sickness was caused by a small blood parasite, a trypanosome, something like that which was carried from animal to animal by the tsetse fly, that this fly took the trypanosome from the blood of wild animals and passed it on to horses, and that if trypanosomes were injected into the blood of a monkey it suffered from sleeping sickness. It was shown that in Uganda the distribution of sleeping sickness and the distribution of a particular kind of the tsetse fly were the same, and that the tsetse fly only flourished on that part of the lake shore where forests and deep jungle growths came near. The fly required clear water and forest. It was on the edge of the lake that the natives held their markets with the islanders, and were bitten by the tsetse fly as they lay on the shores. As to preventive measures, Prof. Koch had recently brought forward the theory that the chief food supply of *Glossina Palpolis* was crocodiles' blood. That theory required proof. *Glossina Palpolis* existed in places where crocodiles did not exist, and in the laboratory it fed on any animal food offered. As to cures, there was no single well-authenticated case of cure of the disease in man, and all attempts to render him immune by an anti-toxic serum had failed.

Medical Man sued for Motor Car Collision.

ON March 16th, at the Manchester County Court, a collision between two motor-cars in Stockport Road, Ardwick, on the 25th of October last year, was the cause of a claim of £22 18s. 6d. damages. The plaintiff was Mr. William Myerscough, pork butcher, and the defendant was Dr. Dyas.

The case for the plaintiff was that Mr. Myerscough, driving a small car was passing a horse and lorry, when a large car came at a rapid pace without having given warning. The big car swerved to the left to avoid the horse and lorry, and, seeing that an accident could not be averted, plaintiff swerved to the right. The front wheel on the right hand side of the big car struck the near back wheel of Mr. Myerscough's car, smashed it to pieces, and threw out three of the four occupants, with the result that one of them had not yet recovered from her injuries.

In answer to Mr. Pearson, who represented the defendant, Dr. Dyas described the plaintiff's speed as "terrific," and alleged that his own was only about five miles an hour.

The defendant's chauffeur said his own pace was about five miles an hour, while that of plaintiff was thirty or thirty-five. Other witnesses described plaintiff's speed as about thirty miles.

In giving judgment His Honour said the accident seemed to be one in which certain blame attached to each party, and the verdict would be for defendant without costs.

Phthisis made Notifiable.

AT a meeting of the Lanchester Joint Hospital Board, on March 12th, a letter was read from the Lanchester Guardians, intimating that in future phthisis must be regarded as a notifiable disease, and all patients sent to the Maiden Law Sanatorium must have the cost of their care and maintenance borne by the constituent authorities, in the same way as any other infectious disease. It was decided to forward copies of the letter to the various District Councils in the Union, asking for their opinion on the subject.

Pontypridd Medical Appointment.

PONTYPRIDD Education Committee on Wednesday night selected the following candidates as a short list for the appointment of a medical inspector of school children:—Dr. E. F. Thomas (Cardiff), Dr. L. W. Pole (Edinburgh), and Dr. E. J. Griffiths (Swansea). The position is worth £200 a year, rising to a maximum of £250.

Cardiff Medical Staff.

DR. HARVEY BAIRD, third assistant medical officer at Colney Hatch Asylum, London, was on Monday week appointed senior assistant medical officer of the Cardiff Mental Hospital at a salary of £200 a year, rising to £250. Dr. M. F. Caldwell, Belfast, was appointed junior assistant medical officer at the Cardiff Mental Hospital at a salary of £150, rising to £180.

Society of Apothecaries of London.

THE following candidate, having passed the necessary examinations, has been granted the L.S.A. Diploma of the Society, entitling him to practise Medicine, Surgery, and Midwifery:—A. H. Turner.

WE regret to learn that Mr. Sidney Appleton, senior member of the firm of that name of medical publishers, of Bedford Street, London, died suddenly a few days ago. The deceased will be remembered as publisher of such well-known works as "Osler's Medicine," "Holt's Infancy and Childhood," etc.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Locum Tenens.—You will find advertised in our present issue three vacant appointments at the Hospital for Sick Children, Great Ormond Street, probably the largest children's hospital in Europe. There is a small salary, with board and residence, attached to each post, and, if successful in your application, we think you will get just the knowledge and experience here required.

PLEA FOR A SIMPLER LIFE.

How few a simple life will lead,
Just eating what they only need
  And drinking when they're dry;
While many live to gorge and stuff,
And never think they have enough;
  And so, untimely die.

Ah! yes, it is "the pace that kills,"
In spite of homœopathic pills,
  Or Continental cure!
The rush, the hurry, and the race
For money, pleasure, power, or place;
  Better "live slow and sure."

A. D.

Mancastrian.—Beer is certainly not the only offender. Quite recently Dr. Cazeneuve, of the Faculty of Lyons, called attention to the fact that within recent years wine-growers in France have got into the habit of using arseniate of lead as a radical means of destroying insects and mildew on the vines. The arsenic contained in the mixture destroys the insects, but traces of both arsenic and lead are found in the wine derived from such vineyards. The percentage is something like one-thousandth of a milligramme per litre, but this is probably sufficient in the long-run to poison anyone's stomach. Six months of a regime of highly-arsenicated wine is, according to Dr. Cazeneuve, sufficient to tell on the system, and there is danger of wholesale poisoning.

Meetings of the Societies, Lectures, &c.

Wednesday, March 25th.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. R. Johnson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. E. F. Buzzard: Compression Paraplegia.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, March 26th.

Harveian Society of London (Stafford Rooms, Titchborne Street, W.).—Sir Almroth Wright: Some Points in Connection with Therapeutic Immunisation. (Harveian Lecture.)

Royal College of Physicians (Pall Mall East).—5 p.m.: Sir James Sawyer: Points of Practice in Maladies of the Heart.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. H. S. Clogg: Peri-colic Inflammation.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie)). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Lecture-Demonstration:—Mr. A. de Prenderville: Some Recent Advances in Anæsthetic Technique.

Hospital for Sick Children (Great Ormond Street, W.C.).—4 p.m.: Lecture:—Dr. Thursfield: Leukæmia in Children.

Friday, March 27th.

Royal Society of Medicine (Epidemiological Section) (20, Hanover Square, W.).—8 p.m.: Discussion on the Etiology of Typhoid Fever. Papers by Drs. E. C. Seaton, D. S. Davies, I. Walker Hall, Meredith Richards, J. H. Brincker, and Dr. W. H. Hamer: Relation of Bacillus Typhosus to Typhoid Fever.

Royal Society of Medicine (Electro-Therapeutical Section) (20 Hanover Square, W.).—8.30 p.m.: Papers:—Dr. J. Goodwin Tomkinson: Cauterisation as an Adjunct to Radiotherapy. Dr. A. Howard Pirie: On the Value of the Electrolytic Method of Measuring X-Rays.

Medical Graduates' College and Polyclinic (22 Chenies Street, W. C.).—4 p.m.: Mr. H. Tilley: Clinique. (Ear.)

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Surgical Operations (Mr. Edmunds). Cliniques: Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 p.m.: Medical In-patient (Dr. M. Leslie).

Appointments.

Dewar, T. F., M.D., C.M.Aberd., Medical Officer of Health to the Fife County Council.

Glegg, R. Ashleigh, M.D., B.S.Edin., Medical Officer of Health and Chief Medical Inspector of School Children for the Parts of Lindsey.

McElligott, M. G., F.R.C.S.Irel., D.P.H., Honorary Surgeon to the Wigan Division of the St. John Ambulance Brigade.

McHattie, Thomas J. T., M.B., Ch.B.Edin., Casualty Officer to the Great Northern Central Hospital, London.

Rentzsch, Sigismond H., L.R.C.P.Lond., M.R.C.S., Clinical Assistant to the Birmingham and Midland Hospital for Skin Diseases.

Rowntree, Cecil, M.B., B.S.Lond., F.R.C.S.Eng., Registrar to the Cancer Wards of the Middlesex Hospital.

Stallard, H., L.R.C.P.Lond., M.R.C.S., Honorary Physician and Referee for Newark to the Royal Midland Counties' Homes for Incurables.

Stevens, Andrew Norris, L.R.C.P.Lond., M.R.C.S., D.P.H. Camb., Assistant Medical Officer of Health of the County Borough of Great Yarmouth.

Vacancies.

Borough of Ipswich.—Assistant Medical Officer of Health. Salary, £150 per annum. Applications to Will. Bantoft, Town Clerk, Town Hall, Ipswich.

Canterbury Borough Asylum, Canterbury.—Assistant Medical Officer. Salary, £140 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Kent County Council.—Medical Officer of Health. Salary, £800 per annum, with travelling expenses. Applications to W. B. Prosser, Clerk of the Kent County Council. Sessions House, Maidstone.

Newcastle-upon-Tyne Dispensary.—Resident Medical Officer. Salary, £250 per annum, with furnished residence. Applications to the Honorary Secretary, Joseph Carr, Bank Chambers, 26 Mosley Street, Newcastle-on-Tyne.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer for eight months Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician for eight months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

Births.

Bennett.—On March 21st, at Hillcrest, Northwood, the wife of Norman G. Bennett, M.A., M.B., B.C., L.D.S., of Brook Street London, W., of a son.

Lee.—On March 19th, the wife of William Edward Lee, M.D., F.R.C.S., of 45 Muswell Rise, N., and 36 Finsbury Pavement, London, E.C., of a son.

Marriages.

Cleverton—Thring.—On Feb. 11th, by special licence, at Singapore Cathedral, Thomas Charles Albert Cleverton, Surgeon, Colonial Service, youngest son of F. W. Cleverton, of Saltash, to Una Aileen Powlett, elder daughter of the late Major W. P. Thring, R.A.

Deaths.

Colvin-Smith.—On March 21st, at 5 Cresswell Gardens, South Kensington, Marian, the beloved wife of Surg.-General Sir C. Colvin-Smith, K.C.B., K.H.S., M.D.Aberd., after pneumonia succeeding a long illness, aged 76.

Stilwell.—On March 21st, at Lynwood, Beckenham, Ann Louisa Stilwell, daughter of the late George Stilwell, M.R.C.S., of Epsom, in her 68th year.

BROMURAL (Knoll)

(α — Monobrom — iso — valerianyl — urea).

As regards its action, it occupies a position midway between the hypnotics on one hand and the bromides and valerian preparations on the other. It is a

HARMLESS, POWERFUL NERVE SEDATIVE AND MILD HYPNOTIC,

which causes no by or after-effects, and forms the preliminary for a short, healthy, dreamless sleep, from which the patient awakes fresh and invigorated.

DOSE:— as a sedative, - - - 5 grains several times a day.
as a hypnotic - - - 10 grains before bedtime.

EUSTACE MILES
PROTEID FOOD

THE LANCET, Feb. 8th, 1908, says—

"These foods in general show, according to analysis, a high nutritive value in regard to all classes of material which minister to the needs of the body. The food for infants contains a well-balanced proportion of proteins, fats, carbohydrates, and mineral matter. It is a particularly satisfactory fact that this food showed no deficiency in regard to fat. We have also examined cocoa, biscuits, and soup tablets, which all evidenced a rich proportion of nourishing constituents."

"I like the idea of the Two Irons in Hemaboloids"

was the comment of a physician to whom this preparation was presented, and this peculiarity is worthy of special note.

Each Tablespoonful of Hemaboloids contains an amount of iron equal to that contained in 20 minims (1.33 c. c.) Tr. Ferri Chlor.

1. The larger part of the iron in Hemaboloids exists in organic combination with the necleo-proteids obtained from vegetables rich in iron.
2. This vegetable food-iron is reinforced or "ferrated" with a less resistant organic iron compound, in order to more readily neutralize the sulphur-bearing compounds in the bowel, thus preventing the destruction and permitting the absorption of the food-iron in Hemaboloids, as well as that contributed by the daily food supply.

Dose: One Tablespoonful 3 or 4 times a day. Children in proportion.

Valentine's Meat-Juice

For **Ease of Assimilation, Nutrition** and **Stimulation,** for **Power in Sustaining, Restoring** and **Blood-Building,** when other foods fail, in the treatment of **Gastric** and **Intestinal Troubles, Febrile Conditions** and **Wasting** and **Debilitating Diseases,** Valentine's Meat-Juice is extensively employed by well-known European and American physicians

In Hospital Practice.

A. Reeves Jackson, M. D., *President and Professor of Gynaecology, College of Physicians and Surgeons, Chicago; Surgeon in Chief Woman's Hospital of the State of Illinois, U. S. A.:* "Our hospital is devoted exclusively to the treatment of the Special Diseases of Women, and many of the cases, through long suffering, become anæmic, debilitated, and have feeble digestive powers. These do not so much need drugging as they do a full supply of easily digestible, blood-making food in the smallest bulk. This need Valentine's Meat-Juice admirably supplies, and thus far we have not found a single case in which it was not beneficial and did not agree with the stomach."

Prof. Dr. M. Dufour, *Physician to the Ophthalmic Hospital, Lausanne, Switzerland:* "I have recently found Valentine's Meat-Juice most useful in the case of a child suffering from Appendicitis. I frequently prescribe Valentine's Meat-Juice, and have done so ever since it was used most successfully in the treatment of a member of my own family when he was ill some years ago."

W. S. Tremaine, M. D., *Professor of Surgery, Niagara University; Consulting Surgeon Maternity, Emergency and St. Francis Hospitals, Buffalo, N. Y.:* "I have much pleasure in stating that I have used Valentine's Meat-Juice for more than ten years and can testify to its excellence. I know that I have saved lives with it when every other form of nourishment was rejected. It is a most valuable preparation, and I constantly use it."

"I have used Effervescing **Bromo-Soda** very extensively, and can cheerfully recommend it to my professional brethren. The addition of the grain of Caffein Hydrobromate to the thirty grains of Sodium Bromide I think a most happy idea. I recommend your Bromo-Soda because I have used Sodium Bromide for years, instead of the Potassium Bromide. Sodium Bromide is not a foreign salt in the system is much less depressant, can be used where the heart is extremely weak, and does not impair the integrity of the muscular tissue; does not cause bad breath, neither does it cause acne, nor impair pharyngeal sensibility. It is much more palatable, and has the happy faculty of agreeing with the stomach, where the corresponding Potassium Salt often gives us so much trouble. I find Effervescing Bromo-Soda very valuable in cases superinduced by overwork of a mental kind; in fact, at times, when overworked, I have refreshed myself with a little in water."—J. K. B——, M.D., LL.D.

The
'Allenburys' Foods

Special Advantages:

1—The close conformity in composition of the Milk Foods to human milk; both fat and proteids being in similar relative proportions.

2—The readiness with which the Foods are assimilated; being as easy of digestion as maternal milk.

3—Their adaptability as an adjuvant to breast feeding during the period of weaning; no digestive troubles being likely to occur.

4—Their freedom from all harmful bacteria; being made from fresh milk, modified, evaporated at a low temperature, in vacuo, and preserved in hermetically sealed tins.

5—The ease and exactness with which the Foods can be prepared; the addition of hot water only being necessary.

6—Fresh elements of diet can be easily added to the Foods, and are specifically mentioned on each tin.

A reliable substitute is thus provided for the Mother's Milk, when this is wanting or deficient.

MILK FOOD No. 1. From Birth to 3 months.
MILK FOOD No. 2. From 3 to 6 months.
MALTED FOOD No. 3. From 6 months upwards.

A descriptive Pamphlet, giving Analyses, etc., and Samples of the Foods will be sent on request.

NOTES AND COMMENTS.

Mr. Bernard Shaw and Anæsthetics.

MR. BERNARD SHAW being now in full practice as a genius, finds it necessary to say something *bizarre* on every subject of passing interest, in order that his dutiful followers may know what line to follow, or, at any rate, to give them a fresh opportunity of applauding the freedom of their master's spirit from the toils of a wearisome conventionality. The Medico-Legal Society have lately had under discussion the question of "The Legal Liability of the Anæsthetist," which we should judge to be a technical matter admirably adapted for decision by gentlemen of medical and legal learning, and quite beyond the prowess of persons acquainted with neither subject. Presumably, however, the opinions of certain outsiders were invited, for a letter was sent by Mr. Bernard Shaw, and duly chronicled by an obsequious Press, to the following effect:—"The intelligent layman is no more interested in anæsthesia than in hanging, because he doesn't intend to get operated upon any more than he intends to be hanged. When he does get operated upon what annoys him is the discovery that the beneficent discovery that is to save him all pain not only makes him so abominably sick that he swears to do without it next time, but also spares him nothing but the actual knifing, leaving the pain of the wounds unalleviated—in short, that it makes things much easier for the surgeon than for him."

Fun v. Folly.

BEING, ourselves, so far removed from the plane on which genius operates as to be able to view its gyrations with an impartial eye, we can candidly express the opinion that we never read such an ineffably silly letter, even in the correspondence columns of "Home" magazines for ladies. That it represents the best effort of the discoverer of the nuciform sac is only credible on the supposition that the master having said all the clever things and all the funny things of which he is capable, is reaching a dotage in which he must make up in venom what he lacks in wit. The effusion leaves the point at issue untouched, and Mr. Shaw had a fine opening for a sally if he had kept to it; but the temptation of having a cheap scoff at one of the greatest boons which modern medicine can provide was too strong for a gentleman who delights to sneer at medical science when he gets a chance. It is true that the intelligent layman does not intend to get operated on if he can help it, but it is equally true that the layman—intelligent, inspired, or merely commonplace—who has not been operated on is becoming something of a rarity, and he who has so far escaped knows that the day may not be far distant when, for the relief of pain, for the avoidance of danger, or for the correction of deformity, he may be glad to undergo the "actual knifing," and then the assuaging influence of a general anæsthetic will be unspeakably grateful. We venture to predict that Mr. Shaw, should his misfortune be such as to require an operation in the future, will forget his bravado and silliness and thankfully accept the blessing of anæsthesia.

Feeding Stuffs.

AT the useful Conference on Infant Mortality which has been sitting at Caxton Hall, an effective paper was read by Dr. Eric Pritchard on the regulation and control of food and drugs for infants. The points he dealt with are subject to more popular misunderstanding than almost any others. Patent foods have a place in the dietaries of invalids and children, but it is a subordinate one, and much of the stuff advertised in the lay papers is trash of a bad type. Of soothing syrups and teething powders medical men know the harmfulness, but among mothers, especially the poorer ones, these poisons are considered indispensable adjuncts of infant life. In condemning these atrocities, Dr. Pritchard made a telling hit by showing that by the Fertilisers and Feeding Stuffs Act the purity and innocuousness of foods for cattle are supervised and guaranteed, yet for the human infant no such measure is thought necessary. A similar argument was used by the next speaker at the same meeting, Bailie Anderson, who mentioned that the Government gave legislative protection to the wild birds of the air, the trout of the streams, the cattle of the fields, and even to the soil of the fields. "Surely," said he, "it is not too much to ask that the human infant should have at least equal protection." It is more than a reproach to the civilisation of the country that the breeding of bullocks and pigs should be considered a praiseworthy and gentlemanly occupation, while the improvement and protection of the human race is held to be a hobby of faddists and busybodies. The reason, alas! is not far to seek. The better rearing of children connotes better living conditions for the parents, and better living conditions connote smaller profits to those who cater for them.

Publicity of Analysis.

AMONG the resolutions adopted by the Congress was one to the effect "that all preparations offered or sold as foods or drugs for infants should be certified by a Government analyst as non-injurious, and that each packet shall bear an analysis of its contents, and that provisions, similar to the Fertilisers and Food Stuffs Act, should be applied to drugs and foods sold, or purporting to be, for the use of infants." This resolution has a special interest for us. In its application to the purposes for which it is designed we cordially endorse it, and as introducing the principles of Government control and the displaying of the contents of would-be secret bottles or packages, we give it even more hearty welcome. These principles, we have long maintained, form the basis on which all quack medicine business should be regulated. In the Colonies, where it is proposed to introduce them, the trade is infuriated, and what is even more important from the point of view of political exigencies, the hireling press which battens on the advertisements of these preparations is vehemently on the side of the trade. Both interests know well that when only the truth can be told about medicines and foods, the demand for them will sensibly diminish and their profits will sink in proportion. Now, it is important to remember that the Congress on Infant Mortality, though attended by certain medical men, was not designed for the medical profession primarily, or, indeed, at all, but for all persons interested in the subject, and therefore was in bulk composed by lay people. The recognition by such a body of the evils of the trade in infant foods and drugs, and the need for control, is the most hopeful sign we have seen for years that the agitation against quacks and quack medicines is having effect, and that there are cultured people who recognise that medical men are opposed to this nefarious trade, not because they are afraid of their own interests, but for the protection of the public.

Homard au Pain.

AN amusing prosecution under the Food and Drugs Act took place at Blackpool last week. A Southport firm were summoned for selling potted lobster not of the quality, nature, and substance required. The Deputy Town Clerk who prosecuted, said that two sample tins of the "lobster" had been taken and sent to the borough analyst, who found that the contents consisted of 50 per cent. of foreign fish, coloured red with a coal-tar dye, 7 per cent. of bread, and 0.2 per cent. of boracic acid, together with 25 per cent. of genuine lobster. The defendant was deeply indignant, it seems, at the accusation, that bread had been found in his tins, and he produced some stuff in an envelope which he said had been mistaken for bread, but was really a preservative. This rare and costly preservative eventually turned out to be ground rice. Happily, in this case, beyond the 0.2 per cent. of boracic acid, there does not seem to have been anything deleterious to health in the savoury mixture, though the foreign fish dyed red makes one feel that even the air of Blackpool could hardly make it palatable. Perhaps it was this factor that induced the magistrates to deal leniently with the defendants, for they were only fined £3 and costs, but it is not easy to conceive a plainer and more wilful and more carefully executed fraud than to mix these substances together and sell them as "lobster." Considering the bread, we might almost have forgiven the vendors if they had called their goods "lobster sandwiches."

Medical Referees.

MR. HENDERSON, the Chairman of the Labour Party, elicited an interesting piece of information in a question he put to the Home Secretary last week. He ascertained that for the first six months after the Workmen's Compensation Act came into force only 117 cases had been submitted to medical referees under the Act. As Mr. Gladstone remarked, it is not fair to judge of the working of the system by the results of the first six months, but we think they do show in a more or less concrete form that the system is not one which has found the favour it deserves with the employers and workmen. We have little doubt that were employers only in question they would readily make far more extended use of referees, but as the consent of the workman is necessary for a reference, other than one from the court itself, the out-and-out malingerer knows he has a better chance of getting round an arbitrator than round an experienced medical man. It is obviously more to a dishonest workman's advantage to go to court and put his employer to all the expense involved, on the chance of a settlement being offered, than to submit to the simple process of going to a referee for a decision as to whether he is fit to work. It is a great pity that the Act does not make the question of fitness to resume work, which is purely a medical one, a matter for the referee and for him alone.

LEADING ARTICLES.

THE LEGAL POSITION OF THE ANÆSTHETIST.

THE adjourned meeting of the Medico-Legal Society on March 24th dealt mainly with the legal aspects of the administration of anæsthetics. Perhaps the most important outcome of the discussion is the unanimity with which most of the speakers advocated a reform of the law so that the administration of general anæsthetics should be confined to duly qualified medical practitioners. Dr. F. W. Hewitt, who moved a resolution to that effect, commented on the fact that everyone, whether qualified or unqualified, whether experienced or inexperienced, reputable or disreputable, may now administer an anæsthetic. That position was clearly stated by Mr. R. H. Wellington, Deputy Coroner for Westminster; all that the Medical Acts now provide is that the public shall have the means of finding out whether any given individual is or is not regarded by the General Medical Council as properly qualified to practice medicine and surgery. Any member of the public, therefore, is at liberty to employ any unqualified person at his own risk. On the other hand, the unqualified person administering an anæsthetic is in the position of any other quack, inasmuch as he cannot be punished unless he assumes a title implying that he is a properly qualified medical practitioner. Mr. Wellington went straight to the root of the matter by suggesting that the Privy Council should make it penal for any unqualified man to administer an anæsthetic, whether local or general, and that the County Councils should appoint a Registrar to abstract and report on the masses of waste material which exist in the depositions taken at inquests. Dr. Hewitt's resolution was carried, and will be duly forwarded to the General Medical Council. Its full text is as follows: "That, as the administration of any drug, or drugs, with the object of producing generalised insensibility to pain, during a surgical operation or during childbirth, cannot be safely undertaken without medical knowledge and skill, your petitioners humbly pray that legislation be granted whereby the administration of any drug, or drugs, with either of the aforesaid objects, by any person other than a duly registered medical practitioner, or someone acting immediately under his supervision, direction, and instruction, be made a penal offence." Speaking generally, and with full approval of the principle of this resolution, it is impossible to avoid the reflection that if the administration of an anæsthetic by an unqualified person is to be made an illegal act, then also the discharge of many other important acts and functions appertaining to a duly qualified medical man should also be rendered penal. Dr. Hewitt's second resolution, providing that special instruction in anæsthetics should form an integral part of professional education, was also carried. There are, of course, various points to be considered in reference to these resolutions. The Scotch members of the Society deprecate the Coroner's system of inquiry in favour of their own plan of private investigation by the Procurator Fiscal. It was asserted in so many words by one speaker that publicity lead to deaths under anæsthesia by scaring the public. In answer to that objection, the writer may be referred to Dr. F. J. Waldo's recent article published in The Medical Press and Circular of Wednesday, 18th March, wherein he plainly shows that no Scottish statistics exist that are worthy of the name. Until we have fully detailed and trustworthy returns of all cases in which general anæsthetics are administered, whether non-fatal or fatal, we can form no scientific conclusion as to the ratio of deaths to administrations, either generally or as regards the use of particular drugs. Under the circumstances, therefore, any gentleman who claims better results for one system of inquiry than another into fatal cases is simply acting on vague beliefs and non-scientific assumptions, incapable either of proof or of disproof. One practical point raised was whether the L.D.S., without a full qualification as physician and surgeon, is qualified to give any anæsthetic at all: whether, for instance, he may give ethyl chloride, nitrous oxide, or any other general anæsthetic. That is a detail, however, capable of ready settlement when principles have been formally adopted. For various reasons the subject of anæsthetics and their administration has been permitted to drift into a position of neglect that is not warranted by the facts of the case. It is to be hoped that the present revival of interest in the matter will not be allowed to drop until some solid progress has been made in our scientific knowledge of the whole matter, both in the interests of the public and in those of the medical profession.

CURRENT TOPICS.

Conjunctivitis Neonatorum.

The question asked in the House of Commons last week by Lord Hugh Cecil regarding "Infantile Ophthalmia" draws attention to the habit medical men have of using a term which should be obsolete. In the hoary days of old, "ophthalmia," no doubt, was a passable word; then it was that nothing was known of the etiology of the condition to which it was applied; then it was that the term implied anything and everything in the form of eye disease which was accompanied by a "discharge." Just so was it in the days of our forefathers,, when they thought that an inflammation could be "sympathetic" in origin, and thus they named diseases of the eye "sympathetic ophthalmia"—in this sense, from their own point of view, using the word "ophthalmia" wrongly. A correspondent in a contemporary urged that the term "ophthalmia" should be retained, inasmuch as it had been "sanctioned" by use. But, as it was very properly pointed out in reply, to "sanction" an error by anything was impossible. The point, of course, is that the medical student of the present day is taught in his bacteriological class that certain micro-organisms cause inflammation of the conjunctiva—that is to say, conjunctivitis. But afterwards he proceeds to the eye wards, and there the ophthalmic surgeons talk volubly of "ophthalmia." On inquiry, he is informed that "ophthalmia" means conjunctivitis, and he naturally cannot understand why a term to him of such meaningless import should be employed for one which expresses a definite morbid entity. Again, the medical student of the day hears still in many eye wards of "sympathetic" inflammation, and the natural question which he feels inclined to ask of his teachers is: "What is the pathology of sympathy?" Neither in his bacteriological nor pathological classes has he heard of such a term. Doubtless, it may be pointed out to him that both "ophthalmia" and "sympathetic inflammation" are clinical expressions, but being a man whose knowledge is being based upon the broad standpoint of science, he fails to comprehend how these clinical terms can be retained and justified when scientifically they are both inaccurate and misleading. Quite possibly the next generation of ophthalmic surgeons, realising fully the teaching of pathology and bacteriology in this regard, will discard these obsolete terms. Meanwhile, for official purposes, reports upon "infantile ophthalmia" should only contain the term *conjunctivitis neonatorum*.

The Position of the Medical School of the R.C.S.I.

There is no doubt that the letter which has been sent by the President, Vice-President, and Secretary of the Royal College of Surgeons in Ireland to the Chief Secretary for Ireland, in which the writers point out the effects on the College Medical School of the establishment of a new and endowed medical school almost at its door, is worthy of, and will receive, with few exceptions, the sympathy of the medical profession. The matter may be put thus in a nutshell. The College School is threatened both by direct competition and by the possible lowering of fees which the endowment of a new school will render possible. The life of the College is intimately bound up with the school, and the failure of the one may bring in its train disastrous consequences to the other. The Royal College of Physicians is, further, closely dependent on the prosperity of the College of Surgeons and its school, because so much of its income is received from the fees of students who present themselves for the conjoint examinations. Therefore, it may not incorrectly be said that on the welfare of the School of the Royal College of Surgeons depends the welfare of both Royal Colleges in Ireland. Mr. Birrell has been accredited from time to time with the desire to upset many existing interests and institutions in Ireland, but we cannot but believe that he will recognise the enormous importance of doing what he can to preserve the Irish Colleges. There are duties, appertaining to both Colleges, of importance to both the country at large and to the State, and they cannot be discharged by a non-medical body such as a university. Before the State adopts expedients calculated to impair the usefulness of the Colleges, it should consider well whether in doing so it is not injuring itself also. The suggestions offered by the writers of the College letter are, therefore, worthy of the closest consideration, and in pressing them forward we should be glad to see the Royal College of Physicians associated with its sister College.

Notification of Anthrax and Glanders.

LAST week a question in the House of Commons called attention to two recent interesting cases in the City of London Coroner's Court. The first was one of glanders in a man engaged in shipping horses from the Continent. The second was a sporadic case of intestinal anthrax in a nurse, who is supposed to have acquired the infection through food. The spleen was enlarged, and the bacteriological examination revealed unsuspected anthrax. At both inquiries the medical men in attendance agreed that the diseases in question should be added to the list of diseases compulsorily notifiable to medical officers of health. The question asked of the President of the Local Government Board was whether he would take steps to extend the provisions with regard to compulsory notification of disease to all cases of anthrax in human beings, arising from any cause, and to all cases of glanders in human beings, or of suspected glanders. Dr. Waldo, the Coroner, expressed a strong opinion that glanders should be notifiable, a view that is shared by the London Corporation and by Dr. Collingridge, their medical officer of health.

The Mosquito in Yellow Fever.

THE recent issue of the evidence taken by the Royal Commission on Vivisection for the last three months of 1907 contains a mass of interesting matter. Amongst other points, the usefulness of the practical methods of modern science were admirably illustrated by Professor Osler in the case of yellow fever. In 1900 a Commission was sent to Havannah by the United States Government especially to investigate the cause of that malady. That Commission recognised particularly the relations of the mosquito to the disease. The experiments which they devised were carried out in a United States Army camp in Havannah, and they were amongst the most remarkable that had ever been made. The camp was composed of a certain number of immunes—that is to say, persons who were no longer susceptible to yellow fever in consequence of having had it. In this camp a house was constructed of two compartments, divided from each other by a wire mosquito-proof screen. Into one side of this hut fifteen infected mosquitoes were placed. Men were selected, partly from the Army and partly from civil life, who had expressed and signed their willingness to submit themselves to experiments, and one or two of the medical men also volunteered. Into the compartment with the fifteen mosquitoes a non-immune went in the morning, in the afternoon, and on the following morning and submitted himself to the bite. Within five days he had the disease. At the same time, in the adjacent compartment, which was simply screened from these mosquitoes by a wire netting, for twenty-one consecutive nights two non-immunes slept. They did not get the disease. This series of experiments, Dr. Osler added, had already revolutionised life in those regions. Havannah within the following two years was cleared of yellow fever, the first time in the 300 years of its existence.

The Indian Plague Commission.

THE Indian Government has issued an interesting summary of the work of the Plague Commission, entitled "The Etiology and Epidemiology of Plague." The conclusions are as follows:—1. Pneumonic plague is highly contagious. It is, however, rare (less than three per cent. of all cases), and plays a very small part in the general spread of the disease. 2. Bubonic plague in man is entirely dependent on the disease in the rat. 3. The infection is conveyed from rat to rat and from rat to man solely by means of the rat flea. 4. A case of bubonic plague in man is not in itself infectious. 5. A large majority of plague cases occur singly in houses. When more than one case occurs in a house, the attacks are generally nearly simultaneous. 6. Plague is generally conveyed from place to place by imported rat fleas, which are carried by people on their persons or in the baggage. The human agent not infrequently himself escapes infection. 7. Insanitary conditions have no relation to the occurrence of plague, except in so far as they favour infection by rats. 8. The non-epidemic season is bridged over by acute plague in the rat accompanied by a few cases amongst human beings.

The Bona Fide Midwife.

AT a meeting of the Central Midwives Board last Thursday, charges against thirty midwives were investigated. Dr. Champneys announced at the outset that up to the end of February, 1908, the total number of midwives crossed off the roll for various offences was 118; of these, 115 were enrolled under the *bonâ fide* clause. The evidence produced in the hearing of the present thirty cases contained some interesting information as to the routine work of the "old style" country midwife—the kind that is passing away. Twenty out of the thirty were struck off the roll, one had died since she was cited to appear, and the neglect of the Local Supervising authority to notify this fact cost the Board some £5. The remaining nineteen were censured or cautioned. Most of the charges were concerned with uncleanliness, not using the appliances prescribed by the rules, and neglecting to send for medical aid where it was needed. Three were charged with intemperance, and were struck off. In the course of the evidence, twenty-two cases of puerperal fever were revealed in the practice of these women, some of them being fatal. One midwife, working in Manchester, charged with neglect of two patients, who both developed puerperal fever, proved that she had so many cases at the time that, being unable to find another midwife to relieve her, she could not possibly attend to them all personally. There were several letters from medical men and others, giving ample testimony to her good work and character, and the Board contented itself with passing a vote of censure, the Chairman adding a few words of caution to the midwife on the mistake of undertaking more work than she could perform, and her responsibility to those she took charge of. Eight of the cases came from Staffordshire, where considerable ignorance appears to prevail among the midwives, and the two inspectors of the county, Dr. Alexander and Miss Wooldridge, appeared to give evidence. In one case of a premature infant—one of twins, the other being still-born—both mother and midwife stated that the child would take no food, though they tried it with gruel! The child died seven days after birth, no medical aid having been called in.

The Irish Housing Bill.

It is a matter for congratulation that the Irish Housing Bill, which passed the second reading last week, has received the support of all parties in the House. It is said that the financial clauses of the Bill in their present condition are not quite satisfactory; but this is a matter which may be set right in committee. The principle of the Bill—to do away with the necessity of going to Parliament for sanction of every little slum clearance scheme and making the decision of the Local Government Board final—has been accepted, and if along with this the Treasury can arrange to advance money on easy terms, then a great advance will be made toward the good housing of the people of Ireland. The municipalities have not been unmindful of their duties in this respect, but they have been hampered by their limited borrowing powers, and the expensive necessity of obtaining parliamentary sanction for each individual scheme. In many of the towns of Ireland the provision for housing the poor is very inadequate. Thus in Dublin, of 59,263 tenements, 21,747 are tenements of one room. That is to say, over 20,000 families inhabit one room to each family. The proportion of such tenements in Manchester is 0.04 per cent., in Liverpool 0.22, London 0.57, in Edinburgh 1.80, in Glasgow 4.28, and in Dublin 8.64. We trust that the Bill will speedily pass into law, and that its expeditious working will go far to remedy this sad state of things.

Indecent Literature.

We are glad to see that a Committee of both Houses of Parliament has been appointed to consider and inquire into the law as to lotteries, and "as to indecent literature and pictures and advertisements relating to things indecent and immoral." Our columns have frequently contained protests against the ease with which indecent advertisements are sent through the post, and only last week we had to refer to the particular instance of respectable ladies who have recently given birth to children being insulted by receiving through the post advertisements of the most gross description. It is intolerable that the public mails should be used for such purposes. There should be some stringency exercised also towards the indecent advertisements which crowd the columns of the daily and weekly papers, notably the lower-class sporting and religious prints. The proprietors of these organs will not lightly deprive themselves of the subsidy they receive for the publication of this sort of matter, but they may be made to feel that they cannot any longer play with impunity the part of go-between in this vile traffic. We hope that these, as well as other matters of the kind, may be brought to the notice of the Select Committee.

PERSONAL.

The Prince of Wales personally presided on March 20th at the annual meeting of the President and General Council of King Edward's Hospital Fund for London, to receive the accounts and reports for 1907.

Dr. David J. Thomas and Dr. D. Jenkins Thomas have been placed on the Commission of the Peace for Glamorgan.

Dr. H. R. Dean, of Magdalen College, Oxford, has been elected to the Radcliffe Travelling Fellowship for three years.

Dr. William Duncan has resigned the post of Obstetric Physician to the Middlesex Hospital, which he has held for close on twenty years.

Dr. Joseph Hume Patterson, Senior Assistant Bacteriologist to the Corporation of Glasgow, has been appointed Bacteriologist to the Lanark County Council.

H. Stallard, B.A.Cantab., L.R.C.P., M.R.C.S., has been appointed Honorary Physician and Referee for Newark to the Royal Midland Counties' Home for Incurables.

Dr. Arthur Newsholme, Medical Officer to the Local Government Board, was entertained at dinner on March 21st by a large number of the leading citizens of Brighton.

On March 19th, Sir Malcolm Morris, K.C.V.O., was entertained at dinner at the Imperial Restaurant by a group of friends to congratulate him on the honour conferred on him by the King.

Drs. Henry Gervais and G. E. Herman have been elected Consulting Physicians to the Royal Maternity Charity, London, in place of Dr. Robert Barnes and Dr. Fancourt Barnes, both recently deceased.

Mr. George Canning is being sent out to Sekondi by the Colonial Office to assist Professor Simpson and other experts already in West Africa in dealing with the plague epidemic.

Captain F. J. Brakenbridge, R.A.M.C., has been allowed by the King to accept and wear the 4th Class of the Order of the Medjidieh conferred on him by the Khedive in recognition of his services.

Mr. H. N. Hamilton Hoare, who has been the hon. treasurer of the Hospital Saturday Fund since its establishment in 1873, has, to the great regret of the committee, resigned that position, in consequence of ill-health.

The Earl of Rosebery, in his capacity as Chancellor of the University of London, on March 26th visited University College, London, for the purpose of formally opening the new libraries and the south wing, by which the college has just been enlarged.

Dr. Scanes Spicer has been elected Consulting Surgeon for Diseases of the Throat to St. Mary's Hospital, on resigning his post on the active staff. The Board of Management, in passing the resolution, conveyed their best thanks to Dr. Scanes Spicer for his valuable services for the last twenty years.

Dr. Frederick Melland, of Victoria Park, Manchester, is one of the city's veteran surgeons. Though he has passed his ninetieth year he still enjoys vigorous health, and at the Oldham Chamber of Commerce dinner the other evening Sir Frank Forbes Adam remarked, as evidence of his remarkable vitality, that "he had not passed a single course nor yet one of the wines."

A Clinical Lecture

ON

TWO CASES OF

SUBACUTE INFECTIVE EPIPHYSITIS. (a)

By EDRED M. CORNER, M.C.Cantab., F.R.C.S.Eng.,

Surgeon to Out-Patients at St. Thomas' Hospital and at the Hospital for Sick Children, Great Ormond Street, London.

[In opening the lecture a patient who had been shown at the Clinical and Medical Societies in 1906 (*b*) with diffuse chondromatous enlargements of the ends of the bones in one leg was demonstrated, the conditions being illustrated by skiagraphs, photographs and drawings].

The two following cases have been selected to be discussed in the present lecture because they illustrate a pathological state of epiphysitis due to an infection with micro-organisms which we are only just beginning to recognise clinically. The second case will be more fully reported at a later date with a full account of the bacteriological findings.

Case I.—A. L., a little girl, æt. 5, was sent to me by Dr. J. D. Shapland, having been ill for 9 or 10 days previously. Dr. Shapland had come to the conclusion that there was a condition of infective inflammation in the hip-joint. Her maternal grandfather had died from phthisis. When five months old she suffered from "consumptive bowels." And later, she had rickets, measles, chicken-pox and whooping-cough.

Nine days previous to her admission to St. Thomas' Hospital she complained of pain in the back of the right knee. Four days before admission she complained of pain in the right hip. The fever which accompanied the condition ranged between 100° and 103°. At the time of her admission it was 101.6°., the pulse rate 120 and the respiration rate 32. The temperature quickly rose to 103°. The child lay with both thighs flexed. The left leg can be straightened but any attempt to move the right leg caused pain. There is nothing abnormal about the right knee. The right thigh is a little full in its upper part. In fact there was great paucity of physical signs. On the third day after admission the temperature was 102.4° and the pulse rate 120, whilst some swelling appeared over the great trochanter. It was decided to make an exploratory incision. Under chloroform an incision was made through the swollen tissues down to the trochanter, which was opened with a gouge. No pus was found. By raising the structures in front of the neck of the femur, the hip-joint was opened and explored, no pus being found. The wound was then closed partially. As a result of this not obviously successful operation the temperature fell to 97.6° and the pulse-rate to 100, on the second day. The patient became very comfortable and had no pain. An extension apparatus with a weight of four pounds was put on the limb. On the fifth day after operation the wound which had been left open in part began discharging freely, the temperature varying from 97° to 102° for the next seventeen days. The condition of the part did not appear to warrant such a temperature and my colleague Dr. C. R. Box saw the case. He could find nothing except a slight tonsillitis, and decided that the cause of the pyrexia must be sought in the local condition of the hip. On the 22nd day since the operation the temperature began to decline steadily, becoming normal on the 32nd day. Marked fullness was found in front of the hip-joint. There was no pain so long as the leg was not moved. The right leg was a little more than half an inch shorter than the left. A skiagraph taken by Mr. A. H. Greg showed extensive disease in the head and neck of the right femur. On the 50th day since her admission Mr. J. E. Adams explored the right hip-joint through the usual anterior incision. The head of the femur was found practically separated and was removed. It consisted of a shell of hard bone destroyed in parts, and filled with soft granulation and gritty *debris*. Immediately after operation the temperature rose to 102°, was 102.4° on the following day, after which it became normal. The hip was allowed to anchylose to the pelvis in the abducted position. The child was discharged on the 80th day since her admission with a slight discharge from both incisions. Dr. L. S. Dudgeon examined the head of the femur which he reported as a chronic granuloma with some acute inflammatory signs present, "no evidence of tubercle."

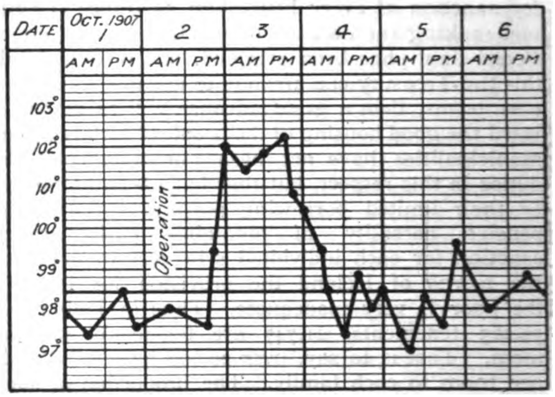

Chart of Case I, showing when the second operation was done and the subsequent rise of temperature

(b) Medical Society's "Transactions," XXX. 1907. Pp. 360-364 Clinical Society's "Transactions," XI. 1907. P. 244.

The point of greatest interest about the case is undoubtedly the origin of the disease; pathologically, it was an epiphysitis; clinically, there was considerable difficulty in ascertaining the precise locality of the disease which required an exploration, and later, an excision of hip; the result being some fibrous anchylosis and shortening of the leg. But what can have caused the trouble? Certainly not the tubercle bacillus (*a*) because no trace of it was found besides the clinical history is not consonant with it being too acute. It was undoubtedly caused by some infective agent of unknown nature which possibly obtained an entry through the tonsils which were found to be inflamed. It is a matter of great importance to realise clearly that such cases are due to the action of micro-organisms. And I would suggest that this case sheds light upon the still more obscure one about to be related.

Case II.—A boy, æt. 12, on September 6th, 1907, complained of pain in the outer side of the upper part of the right thigh, which lasted three days and made him quite lame. He was then perfectly well and running about for four days until on the 13th when he limped. On the night of the 13th he had much pain which kept him awake. On the 14th he was seen by Dr. Beddard who found the right leg held rigid and flexed at both the hip and the knee so that the toes only touched the ground. There was no pain when touched over the hip or the knee, but only along the outer side of the thigh. He had a good deal of pain that night. The sudden and acute onset was most unlike tuberculous disease. Whilst there was no history of any injury or of any disease such as tonsillitis or scarlet fever which might have given rise to the condition. A skiagraph was taken which showed no evidence of any disease of bone. The temperature rose to 102.8° in two or three days and then declined. The flexion of the hip was corrected in three days with an extension of the lordosis of the spine diminished. The pain quickly disappeared. And after remaining about 100° the temperature became normal on the 38th day. But there were two suspicious signs; there was continuous loss of flesh and the pulse rate had not subsided with the temperature. On the 55th day the temperature remained up for five days, returning to normal on the 62nd day. There was some swelling in front of the right hip at this time. On the 72nd day the temperature again rose, reaching 101,8°, and remaining up for five days before it returned to normal. This febrile attack was unaccompanied by any great increase of pain in the hip, but was followed by a most troublesome symptom, attacks of vomiting. In front of the outer part of the hip a swelling appeared, over which the superficial veins were enlarged and an indefinite feeling of fluctuation was obtained. There was marked tenderness over the great trochanter. The next day the swelling was rather less marked and obviously less tender. From this time the tenderness and swelling gradually subsided. But on the 90th day of illness the patient had pain in the *left* side, which hurt him when he coughed and kept him awake at night with throbbing pain. On examination, the abdomen did not move so well on respiration. There was a swelling over the left hip which extended on to the abdomen where it caused dulness. The next day the swelling was less, but the temperature remained between 100.4° and 101.2° for ten days. As the swelling in front of the left hip subsided, the abdomen became resonant again and the glands in the groin were felt to be enlarged and hard. On the 94th day he complained of pain along the back and inner part of the left thigh, extending as far as the popliteal space. On the 96th day this area was less tender but there was marked tenderness and swelling in the popliteal space, accompanied by flexion of the knee. On the 101st day the temperature was normal and there was marked improvement in appetite and general condition. But a tender swelling had appeared at the junction of the upper and middle thirds of the left calf, followed by some swelling of the left foot. On the 115th day samples of blood were examined by Dr. Klein and found to be absolutely sterile. Since this date all the signs have disappeared, and the boy has improved much in appearance, but his pulse rate is rarely under 100, and he has developed starting pains at night in the right hip.

This boy presented three distinct features which lead to great difficulty in his treatment; attacks of vomiting, desquamation of the skin, and easy formation of sores on the skin. The sickness was undoubtedly in part functional, being excited in particular by being pressed to take food, being offered food he disliked, or by visitors talking about food. Pain, such as was caused in putting on the Thomas' splint always brought on sickness; as, also, would an enema at times. It constituted a very great difficulty in feeding the boy, and was undoubtedly the cause of much of his wasting. In the middle of his illness it was associated with some headache, when the possibility of tuberculous meningitis was discussed. The symptom has at last been overcome by constant care and patience.

A very curious feature about the illness is the desquamation of the skin which was noticed throughout his illness and was present when the temperature was raised or normal. Indeed, variations of the temperature were not noticed to have any effect on the desquamation. It is most marked on the right leg, whose hip-joint is affected, and which has peeled completely several times. On occasions very tender places have been left on the toes, and sometimes on the face, where the epithelium has been shed.

Associated with the desquamation has been a great liability to the formation of sores. Any point of even the mildest pressure from the splint or extension apparatus will produce them. The ulceration commences insidiously beneath a crust of desquamated epithelium, which when shed or removed displayed a very painful shallow ulcer with shelving edges. In consequence of these sores, the extension apparatus was disused which is now felt to have been unfortunate, though it is very difficult to see how its use could have been continued.

These two cases when compared show many similarities. In both of them the trouble began in the right hip-joint, the onset of the disease being obscure and rather acute. Both children were perfectly healthy before they were attacked. In both cases the temperature rose to 103° in the early part of the disease. And what is of still greater importance although the temperature became normal, in neither did the disease come to an end or, to all appearances, cease to progress. Thus there were some features of acute disease,

---

(*a*) By mistake other organs were not looked for.

such as acute epiphysitis, and others of chronic disease, such as tuberculous epiphysitis. The clinical picture of such a pathological mixture was very poor in physical signs. In fact, in both cases the paucity of signs was so great as to cause doubt as to the actual site of the disease. This rendered it difficult to decide upon both the diagnosis and the treatment. In both cases, the acute character and onset would seem to exclude tuberculosis. And the supposition was justified by the pathological findings in the first case.

A point of clinical interest is, that in both cases a skiagraph was taken by a skilled and competent radiographer in the early stages of the disease. In both cases the bones showed no sign of disease. Whilst in the later stages of the first case, the X-rays revealed the presence of disease in the bone; the decision being confirmed by the operation.

In the second case the occurrence of starting pains shows clearly and clinically that there is some disease of the bone. Hence it is clear that the X-rays are of no use at the commencement of the disease, but are only of value in its later stages when the clinical signs become sufficiently obvious for their use to be dispensed with.

There can be no doubt that the treatment of these cases is best palliative at first because the exact site of the disease is uncertain, and, being the result of an infection through the blood stream, it is impossible to be sure that the present lesion is the only one which will be formed. Under such circumstances it is undoubtedly better to wait and watch the case, not running the risk of proceeding quickly and unwisely. Moreover, there is no need for operative interference in every case. It is undoubtedly a subacute infective condition. Acute infective conditions require operation in every or nearly every case. Chronic infective conditions require operation only in the minority of their numbers. As subacute cases are intermediate between the acute and the chronic, it is obvious that far less cases will require operation than with the acute disease, and far more will require operation than with the chronic disease. A guessing estimate is that about 66 per cent. of subacute cases will require operation.

In these days of surgery, the question of the advisability of early operation must be discussed. The great difficulties in the way of early operation are the uncertainty of the exact nature and site of the disease, and the uncertainty that there will be only one focus when the origin of the disease is undoubtedly from organisms conveyed to the part by the blood, a true septicæmia. Organisms can equally well be conveyed to other parts. Until a definite and favourable answer can be given on these two questions about a case under observation, the advisability of early operation is beyond the pale of discussion. In very favourable cases the course of the disease may be cut short by early and timely operation. But there can be few cases in which it is possible to attain so desirable a result.

The first of the two cases reported came to operation, whilst the second looks rather as though it would not escape. Still, although starting pains have commenced it is possible that operation can be avoided.

At present it is difficult to account for the disease except upon the suggestion that it is caused by organisms conveyed to the part by the blood stream, a true septicæmia. There is no direct evidence as to the nature of the organisms but similar septicæmic or pyæmic conditions are well known; typhoid abscesses, gonorrhœal rheumatism, tuberculous joints, pyæmic foci, and so forth. (a)

Note.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by William Alexander, M.D., F.R.C.S., Senior Surgeon to the Liverpool Royal Southern and Workhouse Hospitals. Subject: "Three Cases of Inoperable Cancer of the Rectum."***

LUMLEIAN LECTURES.

POINTS OF PRACTICE IN MALADIES OF THE HEART. (b)

By Sir JAMES SAWYER, M.D., F.R.C.P.Lond.

Senior Consulting Physician, Queen's Hospital, Birmingham, &c.

LECTURE I.

Mr. President, Fellows, and Gentlemen,—There is nothing which pathology touches which does not adorn a physician's understanding of the heart. No therapeutics can ignore that organ's weal. Those of us whose memories of cardiac pathology and therapeutics extend over, say, forty years—those practising physicians whose clinical experiences cover a participation in the views and work of our profession which were current at any particular time within those four decades, in our views concerning the several blended subjects of the diagnosis, prognosis, and treatment of maladies of the heart, will be likely to agree that certain shiftings of our points of view in these important matters have been evolved from our joint and several work. Such movements of thought are largely subconscious, and sometimes it is well to note their existence and to take stock of their effects. While several very distinct additions, and some of them enduring ones, have been made to our knowledge of the origins, of the courses and of the treatment of diseases and disorders of the human heart, and whilst amongst those additions to our science and to the resources of our art are to be counted no less signal gains than the invention and the use of Marey's sphygmograph and of his cardiograph, the portentous discovery of a new and a microbic pathology, and Lauder Brunton's great gift of the potent therapeutics of the nitrites, while these epoch-making advances, and many other improvements, perhaps less notable and of less momentum, have been achieved, our physicians' view, while it has broadened and brightened, does not appear to have spread and cleared quite symmetrically. Perhaps it is always so with an art which is perpetually indispensable to humanity, and which rests upon an ever widening and ever deepening science. Forty years ago, the stethoscope of Laennec was biassing us towards a reliance upon its enthralling revelations. That "gift of science to a favoured son," as Stokes called it, dazzled us, perhaps, and not a little. We might sometimes not recollect that physical signs, how plain and positive soever they may be, are not a diagnosis, but only a help to it; at the most, only one of its foundations, and, great and reliable as they are, nothing more. I understand it is a maxim of criminal law that direct evidence is not so reliable as complete circumstantial evidence. So is it in medicine as to diagnosis, even in physical diagnosis. Of the great value of the physical signs of disease, as they are brought out by the stethoscope and other similar aids to their manifestation, we have all been long agreed.

(a) An organism was grown from the head of the femur in the second case, after this lecture had been delivered.

(b) Abstract of First Lecture delivered before the Royal College of Physicians, London, March 26th, 1908.

As Stokes soon pointed out, "it is on the discovery, explanation, and connection of those signs with organic changes, and with the symptoms and history of the case, that Laennec's imperishable fame is founded." (*a*) "With the symptoms and history of the case," of *the* case, be it noted, "case" in the singular, each one by itself, with its own unique individuality. But, forty years ago, physicians, it would seem, had not then quite "got over" the appearance of the stethoscope, and the comparative perfection of the science of auscultation. About twenty-five years ago, and many years after this great advance in auscultation, certain advances in microscopic and in comparative pathology, and in bedside research, turned us, perhaps a little too far for a just balance, turned us from our auscultatory refinements as to defects of valves, and of orifices, and from our explanations, perhaps too mechanical, of physical defects and their consequences, to a fuller and truer examination and appreciation of the part which we had to give in our cardiac pathology and therapeutics to many vital changes in the shape and structure of the heart's flesh and in the form and texture of the blood-vessels. And, now, of later times, with a maturer mind, we find the just mean between these two views; each point of view is taking its right place in a better understanding of the maladies of one of the chief of the central organs of our lives. Amongst those of our leaders who have pointed out such a justly balanced view are two of my distinguished predecessors in this chair, the late Sir William Broadbent (*b*) and you, yourself, Sir, (*c*) each of whom has addressed the College with much illumination upon the principles and practice of physic in regard to diseases and disorders of the heart.

Of much interest would it be to practising physicians to trace the growth of knowledge of the nature and treatment of maladies of the heart, not from the beginning of such a history, for that would be a long account remounting to the remotest records of our art, but during the last hundred years, or, as approximately that time, in the nineteenth century. In ailments of the heart, in that hundred years, a surely grounded hope, and our powers for the patient's good, have grown apace. At the beginning of that century Baron Corvisart, the learned head of the imperial medical service of France, opened his classic book on diseases of the heart with a line of well nigh hopeless sound: "*Hœret lateri lethilis arundo.*" (*d*) True was this sombre superscription in his time, when even Withering's immortal revelation of the curative uses of digitalis, of a decade or two earlier, did not appear to have passed into current professional knowledge. But such was the advance of medicine that Walshe, soon after the middle of the century, was able to declare that the gloomy metres of Corvisart's Virgilian quotation had lost much of their fitness to his subject, and to ask us to rejoice with him, as he did in the last edition of his great book, in 1873, that our knowledge of non-organic affections of the heart had found a wide extension, as to their nature and as to their successful treatment, while he was able to declare too, as he did in his precise and cautious way, that medical means of controlling the progress of structural diseases of the heart had continued to improve, and that their hygienic management had made marked advancement. (*e*) Another distinguished Fellow of the College, Peter Mere Latham, told us that, when he came up to St. Bartholomew's from Oxford, in 1810, the treatise of Corvisart was in the hands of all the students, and that it deserved to be, for in it there was full knowledge of the best kind given in the best way; and he pointed out that Corvisart was the first to bring the whole subject of the pathology and diagnosis of diseases of the heart out of obscurity, that it seemed impossible that the diagnosis of these diseases could have been carried further than Corvisart brought it by anything less than some new discovery in clinical observation, and such discovery was made by Laennec in his momentous invention of mediate auscultation. (*a*) Since Walshe's time the progress he helped so much has been kept up. Our diagnosis has gained in precision, our therapeutics have grown in range and in exactness, in the use of new drugs and in estimation of older ones, while what Walshe called the hygienic management of cardiac maladies has been helped by knowledge of how to live in physiological obedience, and by the reasoned use of physical exercises, such exercises being selected upon a skilled appreciation of the possibilities of each patient. In ailments of the heart it has been as true as it ever is in our practice, that the proportions of our power take measure from the extent and precision of our knowledge. During the later three-quarters of the nineteenth century, and until to-day, the clinical study of maladies of the heart has been carried forward with untiring industry and with much success. In no other part of the science and practice of medicine has more brilliant advancement been won, in practical knowledge and especially in remedial opportunities. It is beyond question that this great progress has been due in a large part to the use of various methods of physical examination, in the investigation and treatment of these affections. These methods have been multiplied, their applications refined; and the results of their employment have been differentiated more and more. Especially has the discrimination of cardiac maladies by the objective signs yielded by percussion and by auscultation been advanced to much precision, and all this by continued and by multiplied toil, by the bright contrivings and long researches of many minds and by the patient labours of many hands. The older physical methods of inspection and of palpation have not been superseded; rather have our later elaborations of auricular methods, in auscultation and in percussion, strengthened the indications and pointed the value of those signs which the watchful eye can see and the erudite hand can feel.

Still limiting this brief retrospect to the hundred years last past, one may note two other important details in which our notions as to maladies of the heart have found significant development. One of these points concerns the frequency of these affections; the other springs in part from a recognition of that frequency, and is that wider view of cardiac diseases and disorders which is giving us a more efficient grasp of their treatment, of their treatment not by drugs alone, but also by hygienics, and by every agency we can bring into use for the help of their therapeutics. The frequency of heart affections, relatively to that of other human maladies, does not appear to have increased of later times.

From the recognition of the abiding frequency of organic diseases and of functional disorders of the heart, and from a truer appreciation of the causes of that frequency, has arisen a great and far-reaching qualification in our view of how far the structural and functional changes which form the maladies of the heart may be dealt with as things somewhat apart, of how far such changes should be regarded as portentous matters with an impress and intrinsic characters of their own, as matters which have a peculiar clinical and vital detachment, as it were, of their own kind. Modern physiology, modern pathology, and physical diagnosis have each widened our view. Our later physiological knowledge has given us proofs to demonstration of how manifold, how intricate, and how widely spread throughout the human body are the influences which govern and affect the circulation of the blood. Physiology has shown us that, at the centre of the human circulatory system, of heart, arteries, capillaries and veins, there lies and works the cardiac

musculature, and near the periphery the musculature of the minuter arteries, and that on these two instruments of power many influences are constantly acting and reacting, according to the needs of the body. More and more have morbid cardiac changes become to be seen as what they are, as incidents, though prominent and often vital ones, in many pathological abnormalities. It is seen that the heart, in its complex functions in health and in their manifold derangements in disease, is the main-spring and active centre, the "prince in the commonwealth," as Harvey called it, (*a*) in a vascular system which comprises, besides itself, and the arteries, capillaries, and veins of the systemic and pulmonary circuits, the lymphatic vessels and the lymphatic glands, together with certain ductless glands, and the blood also, and the various fluids which may be its tributaries. We remember how inseparable are the lymphatic and the sanguineous circulations, how intimate is their connection in structure and in function. The circulating lymph is slowly moving, from the blood and into the blood, exuding from the blood through the walls of capillaries, and flowing back to the blood, with what it may bring with it, through the lymphatic vessels, which vessels come from all parts of the body, and at last form the greater and smaller thoracic ducts, which are always pouring their contents into the blood in the left and in the right subclavian veins. We know how important is this lymphatic circulation, to the blood and to the heart. We know how large is the whole amount of lymph in the healthy living body; it is measured at twenty-five to thirty per cent. of the body weight, that is, at three or four times the amount of the blood. (*b*) As to the place of certain ductless glands in the scheme of the vascular system, we may recall that the fruits of some recent researches show the relationship of the functions of those glands with the beats of the heart. Cyon, who is distinguished as one of the discoverers of the accelerator nerve of the heart, has recently developed his hypotheses that the thyroid, adrenals, and pituitary are glands which have the especial function of regulating the nerves of the heart, and even that the proper action of the pneumogastrics is maintained by a secretion of the thyroid. (*c*)

But our wider view in every case of disease or of disturbance of the heart must be far wider still. Extended and complex as is the vascular system, it is only one of many so-called systems of the human body which are in living co-operation with it. Not one of such systems is there but what is "in touch," so to speak, more or less directly, with each function and with every derangement of the heart, through nervous impulses of excitation, of depression, of inhibition, and these sometimes of thought, of volition, or of feeling, through the conveyance of secretion or of excretion, through rest or unrest, through warmth or cold. We know, with knowledge which is especially particular, how manifold and how close are the connections of the heart, through its innervation, with the brain, with the spinal cord, with the sympathetic system of nerves and ganglia, and through these, with all the parts which they animate and govern. In our view of each case of cardiac affection the complete grasp of the whole case must go with the narrow observation of the disturbed part. While each distinct change in cardiac structure or in cardiac function must be observed separately, must be separately recognised and described, and sometimes traced separately to its pathological origin, while our progress in practice in maladies of the heart cannot add to our knowledge of them without such minute and distinct consideration, yet the whole of each case must be grasped, in its living combinations and in its working relations, if the therapeutics and all other management of the case are to be understood, if they are to be conducted aright. For no detail must the whole be neglected.

In this greater grasp our therapeutics has its own place, and this not only for its own usual, direct, and essential usefulness, but also because of its reflex illumination of our diagnosis, and of our prognosis. The very treatment of diseases, rightly considered, is, as we all know, and as Latham wrote when there loomed largely in his mind the treatment of the very maladies we are now regarding—the very treatment of diseases is truly a part of their pathology. "What they need," as he put it, "and what they can bear, the kind and strength of the remedy, and the changes which follow its application, are amongst the surest tests of their nature and tendency." (*a*) We know that this dictum of a great physician is very true as to cardiac affections. The treatment of diseases of the heart is among the tests of the nature and tendencies of those maladies. In any particular instance of disease the therapeutic response to a remedy is a basis of judgment as to the nature of the case, both in diagnosis and in prognosis.

And, further, a heart case is never only a heart case. A heart case is never a heart case, be it either a functional one or be it an organic one, as so a case may be called. If some neurosis or if some temperamental neurotisms be causes in a heart case, then the whole of such neurosis or all of such neurotism, even to their remotest causation, is in question. If structural change in the heart be the proximate basis of the case, putting aside for the moment the general and local changes of metabolism, or of infection from without, or of degenerative metamorphosis, or of these variously combined, which may be the remoter basis of it—if structural change in the heart be the basis of the case, that change has either begun in the heart and is extending to the arteries, or it has begun in the arteries and is extending to the heart, or it has begun coincidently both in the heart and in the arteries, of which last case we have instances in the more fatty forms of degeneration. For the understanding of a heart malady all its accompaniments must be appreciated.

In the last few years many advances have been won in the histology and physiology of the heart and of the blood vessels. Especially has our knowledge grown as to the government of the heart and of the arteries through their nervous supply. Through this supply it is that the force and frequency of the heart's beats are ruled, that the tone of the arteries is kept up, so far as it depends upon arterial muscularity, and the peripheral resistance is controlled, so far as that complex factor in the blood-flow depends upon the tightening or upon the slackening of the muscularity of the lesser arteries. The paths of innervation through which the heart's beats are roused and hastened, through which they are checked and slowed, through which the arteries, and especially the smaller and smallest ones, are braced or unbraced; the efferent depressor path from the heart, through which, by exact mutual adjustment, the force and rate of the heart's beats and the tone and bore of the arteries are balanced; and, lastly, "the band of His," a singular fibro-muscular fillet, found, with its knot-like thickening, with its branches in the ventricular walls, and forming a union between auricle and ventricle through which systolic impulses spread from the one to the other—all these paths of power have been found. A working scheme of cardiac and cardio-vascular innervation has been made out, and this, in the main, from proven and evident facts, and with small mixture of hypothesis, so that much in cardiac pathology has found explanation therein, and so that our understanding of maladies of the heart has grown, to the advancement of our practice in diagnosis, in prognosis, and in treatment. We all know how an intimate knowledge of this innervation interprets to us in practice many points in the courses of certain affections of the heart. It is sometimes said that we have long relied upon an explanation of the action of the heart which may be called the neurogenic theory. But the heart's innervation and musculature are inseparable in the action of the organ. Our theory of yesterday was a neuro-myogenic theory, with an allowance for contractile spontaneity in the heart's musculature, resting on metabolism. Recent researches give fuller knowledge of the play of this musculature,

of a kind suggestive of therapeutic consequences. The functioning of the heart seems to depend upon several separable qualities in the cardiac muscular tissue. Amongst these are the power of originating its own stimulus to contraction and of distributing it from part to part of the heart, its excitability or sensitiveness to such stimulus, its contractility and its tone. It appears, further, that the function of tone, which is a characteristic of every living muscular fibre of the heart, is most marked in the fibres which encircle the valved orifices and the openings of the veins into the auricles, that the contraction and the tone of the fibres in these situations help in closing the valved apertures, and are wholly effectual in closing the non-valvular orifices when such orifices need to be closed in particular parts of each cardiac cycle. All this later knowledge is full of suggestion in our practice, diagnostic and therapeutic. Such a statement of the action of the heart may be called a myogenic theory. It is, in truth, a myo-neurogenic one. It gives prominence and leads to the functioning of the heart's musculature, in the combined results of the action and interaction of that musculature and the cardiac innervation. Clinically this later teaching increases the significance of changes in the myocardium. From this recent knowledge we may draw a new and a momentous conclusion. It is this. Now that we know that the initiation of the heart's beating is inherent in the musculature of the organ, we see in such a fact a remarkable safeguard for the continuance of the beating of the heart, and for the recovery of that beating after a momentary suspension, in the presence of the paralysing effect of some shock to the heart, of such a cardio-inhibitory shock as may arise from a great somatic muscular effort or struggle, or from violent and profound emotion, or from some traumatism, or from some anæsthetic inhalation. That the cardiac musculature, of its own intrinsic spontaneity, leads, leads under nervous sustenance and regulation, it is true, but that the musculature does lead in the heart's action, can save the beating of the heart from final stoppage, under stresses which, but for this defence, might close its career for ever.

As, then, to the heart in disease, in disorder, and in health, the indebtedness of medicine to her own physiology is enormous indeed. Recent physiology has discovered much concerning the circulation of the blood in our species, and all that it has discovered in that regard bears, or will bear, upon our practice. Our understanding of affections of that circulation in the sick, whether their seat be in the heart, or in the blood-vessels, or in the blood, or wherever elsewhere, or in these in ever-varying combinations—our understanding of these maladies has been cleared, if not finally illuminated, and to the illustration of our practice in every cardiac malady. With regard to the systemic circulation, we now know that, in the midst and at the core of the currency of the blood lies the musculature of the heart, with the musculous arterioles near the periphery. Upon these two living, contractile, and expansile elements the central nervous system, directed and governed by this or that impulse reaching it along afferent nerve fibres, or affected by this or that influence, is continually playing; is playing in balanced, in harmonised, in reciprocal, and in compensatory actions, now in augmentation of contraction, now in inhibition of it, and so, by help of the elasticity of the arteries and the mechanism of the valves of the heart and of the veins, directing the blood flow according to the needs of the body. (*a*) From this newer knowledge, not a little of it the produce of our own time, we may be sure that our future progress as to the care and cure of maladies of the heart will depend largely upon whatever further help physiology may be able to furnish. After the manner of Harvey, and of others of the old time before him, physiology, as a part of medicine, and medicine in her pathology and in her practice, have gone forwards in interdependence; and so it will be, while clinicians make our science more practical, and physiologists our practice more scientific.

(*a*) The abridged account of the circulation of the blood given in this sentence has been expanded and amended from Sir Michael Foster's summary, as given in his "Text-Book of Physiology."

ORIGINAL PAPERS.

OPEN WINDOWS AND ADENOIDS.

By J. SIM WALLACE, M.D., D.Sc.,
Hon. Dental Surgeon to the West-End Hospital for Nervous Diseases.

THE simplest, most definite, and most important truth which preventive medicine has been teaching during the last few decades has been the value of fresh air. This fact has justified many a monograph dealing with the general amelioration in health which has resulted. Curiously enough, the historical or evolutionary justification of the doctrine has not received the attention that such an important principle demands. I do not intend to attempt to supply this want. At the same time I must allude to it, for it was, paradoxical as it may seem, the consideration of this subject which led me to believe that we are not justified under all circumstances in advocating fresh air without any reserve. Moreover, a consideration of the evolutionary justification gives also a rough guide to the limitations, or rather safeguards, which have to be observed under special circumstances. If we look back at the evolution of man, we see that he is undoubtedly and essentially a fresh air animal. Our relations, the monkeys and the anthropoid apes, are animals which specially indicate an urgent need for fresh air if they are to be kept in perfect health. Their arboreal *habitat* has from all time fitted them for fresh air, and when brought to confinement, as in zoological gardens, the absolute necessity for thorough ventilation in their houses is now recognised. Moreover, like ourselves, the monkey tribe is specially susceptible to succumb to certain diseases which are almost innocuous to such animals as rats and mice, which may be taken as types of animals not requiring perfect ventilation to keep them in good health. There appears to be one thing, however, in which we differ from our anthropoid relations in respect to *habitat*. Man is not solely a tropical or sub-tropical animal. To him almost all regions of the globe are habitable, while anthropoid apes, at least, seem quite incapable of living for any time, even in temperate regions, except when most carefully protected from the inclemency of the weather. So, too, perhaps, it was with man before he became more highly differentiated from these animals, until, indeed, his intelligence, his clothing and housing, such as it originally was, allowed him gradually to live in countries less and less tropical. And although at the present day man is adapted to live in northern climates, yet the essential similarity to our anthropoid ancestors is still to be seen in a heavy mortality from the very disease to which monkeys are susceptible when they are brought to live in these climates. It does not need any argument, indeed, to show that man without house and clothing is not fully adapted for all the climates in which he lives. This applies even more strongly in the case of infants and children, who are unable to stand exposure so well as adults. We are certainly justified in saying that ever since man commenced to depart from his tropical *habitat* he must always have had some protection, especially for his children, against the less congenial climates. In other words, a house and clothing become necessities of life. At present I intend to refer only to the house. It was until recently a primitive protection, perhaps, but it had this merit—it was always, with the help of the other primitive comforts obtainable, enough to allow for the continuity of the race. It may have had its faults, it may have been insanitary, it may have been ill-ventilated, especially among cave-dwellers, but, on the whole, its utility justified its existence. Probably many millions have perished on account of the faults of hygiene referred to, and perhaps during the same period man may have become better adapted to his climatic surroundings, although infants and children which were necessarily kept more strictly under the protection of the house may not have become so fully adapted.

What is of special importance to note, however, is that the house existed as a protection against certain extremes or kinds of climatic conditions which are inimical to the well-being of the human body. It may here be said that these kinds of climatic conditions to which I refer do not exist in tropical or sub-tropical regions, so that we as animals had not in our primitive state become adapted to these climatic conditions. It would appear that cold and damp are in general never associated in the tropics. In many tropical localities where the atmosphere is clear, dry, and still at night, radiation is rapid, and very considerable cold may be experienced; but during rainy and damp weather the temperature does not fall to anything like the same extent. When we consider cold and damp, however, such as, let us say, are exemplified in our fogs from November till March, we begin to see something differing from tropical climatic variations, and are justified in doubting if man is altogether adapted for them.

Now let us consider what habit and instinct appear to show. It is hardly necessary to refer to the fact that fires are universally used in cold weather, and this in spite of the fact that it is a more expensive method of maintaining heat than by shutting out the air and heaping on clothes. Now the fire has three attributes to which I would refer. First, it provides warmth; secondly, it ventilates; thirdly, it reduces the humidity of the air. Thus fires are beneficial from all these three points of view. It has not required the advances of science to induce people to put on fires. They instinctively do so. The advances of science have, however, been necessary to induce people to appreciate as thoroughly as they should the benefits of fresh air. But the fresh air doctrine has during the last thirty years been taught with effect, and among the educated classes there are few who do not appreciate it. In fact, it seems to have become a sort of cult, and, notwithstanding the fact that there is an instinctive tendency to shut windows on cold and damp nights, the doctrine of fresh air winter and summer has now become part of the educated man's faith. But here is where a protest must be made, not because of the insistence on fresh air, winter and summer, and night and day, but because of the method most commonly employed to secure it. The neglect to prevent the cold and damp from accompanying the fresh air must be regarded as a serious error. In other words, it is not right to attempt to ventilate a room by simply keeping the windows open if the weather is cold and damp. There are several diseases which the medical profession recognises to be in some way associated with cold and damp, such as catarrhs and rheumatism, but I only wish to refer to one at present—namely, "adenoids." This disease has apparently increased in frequency with prodigious rapidity in recent years, and, what is certainly very suggestive, its increase seems to have been concomitant with the cult of open windows night and day, summer and winter. Moreover, my observations would appear to indicate that the proportion of children affected with adenoids is distinctly greater among the more educated classes who are most scrupulously insistent on keeping their windows open at night throughout the year. Children brought up with open windows appear, indeed, to be about fifteen times more likely to contract adenoids than those who sleep with the windows shut on cold and damp nights, or at least than those who sleep with closed windows throughout the greater part of the year. The few figures which I have so far been able to obtain are as follows:—Of 69 who slept with closed windows, two cases of adenoids were found, while of 49 who slept with open windows at night, winter and summer, 22 cases of adenoids were found. *It will be seen from the above that adenoids appear to be confined almost entirely to those children who sleep with open windows;* but, notwithstanding this, it must not be thought that there are no other contributory causes, or that I abandon altogether the other factors connected with clothing, perspiration, digestion, and the development of the palatal arch which I have previously referred to elsewhere. It would probably be more satisfactory, therefore, if in the collection of further statistics the relative frequency of adenoids were considered class for class and not one class against another, where the other conditions, such as housing, fires, clothing, etc., may be essentially different.

When we consider the question from the point of view of physiology and pathology, and what is already known with regard to the etiology of adenoids, we find that the same conclusion must be arrived at. The first point we have to note is that cold air, especially when damp, causes a certain amount of congestion and catarrh of the mucous membrane of the nose and nasopharynx, and although it may be foggy, and on that account specially objectionable to breathe the air directly into the lungs, we tend more than usually to breathe through the mouth. If the stream of cold air is made greater—as, for example, during considerable muscular exertion, then the congestion and simple catarrh is augmented. Those who skate need hardly be reminded of this. Now, if it is conceded that cold and damp air induce congestion and catarrh, then, if continued sufficiently long, it will tend to produce thickening or hypertrophy also. But, in addition to this, it seems undeniable that the specific catarrhal inflammations are more readily contracted when the mucous membrane is congested from irritation by cold and damp air, and therefore tend to increase the hypertrophy.

Referring to acute catarrhal pharyngitis, De Schweinitz and Randal say, "Exposure to cold really means lessened resistance of the tissue to germ vitality and germ entrance into the substance of the membrane." And, referring to acute naso-pharyngitis, they say:—"Exposure to cold and damp plays the chief exciting *rôle*. Here also should be borne in mind what has already been said regarding such exposure as related to temporary impairment of tissue vitality. As occurring in very young patients, we generally find acute naso-pharyngitis associated with more or less enlargement of the pharyngeal tonsil, which in turn may have resulted from repeated attacks of acute rhinitis."

Whether the above considerations are considered valid or not, it is a fact that cold and damp localities are usually recognised as at least a predisposing cause of adenoids, and if the above explanation is correct, then, instead of cold and damp localities rendering the individual susceptible to adenoids in some vague constitutional way, we see that cold and damp localities cause adenoids, from the simple fact that the cold and damp air is the primary exciting cause itself.

Next, when we consider heredity, we read, for example, in Mr. McLeod Yearsley's book on adenoids, that, "although it cannot be positively said to be hereditary, hypertrophy of the pharyngeal tonsil often shows a distinct tendency to affect several members of the same family." This is a significant fact, and indicates, in my opinion, that the mal-environments of certain families tends to produce the disease in each member of the family. If then, "it is by no means uncommon experience for the surgeon to have to operate upon two, three, or even four or more in the same family for adenoids," and since "this fact has been referred to by nearly every writer of any consequence upon the subject," then it surely is evident that there must be a something in the nature of a very definite and direct cause of adenoids in some families, and that this definite and direct cause is absent in other families. That the definite and direct cause is cold and damp night air seems probable. If we consider treatment, a similar conclusion is enforced. Surgical treatment is recognised as being very satisfactory, although recurrence sometimes happens, but medical treatment—notwithstanding the tendency for the hypertrophied tissue to shrink—seems to be attended with very unsatisfactory results. If medical treatment does not recognise the cause, and if such directions are given as "especially should it be insisted upon that the child shall sleep in a room directly open to the outside," then, in a climate such as ours in winter, medical treatment will probably be unsatisfactory.

It was a consideration of several of the above facts that led me to doubt the advisability of open windows at night in cold and damp weather, and it did not surprise me to find that a direct investigation into the relation between open windows at night and adenoids resulted in the figures which I have already given. Although the relationship seems to be unquestionable, yet, having regard for the other conditions and predisposing causes, I am of opinion that a more extended investigation will not reveal such a startlingly close relationship, especially in those localities which are (unlike the Thames Valley, to which my figures specially refer) relatively free from cold and damp night air.

SEASIDE TREATMENT FOR SICK CHILDREN. (a)

By GEORGE CARPENTER, M.D. Lond.,
Physician to the North-Eastern Hospital for Children.

More general attention on the part of the medical profession should be given to the pressing needs for sunlight and pure fresh air, on the rearing and treatment of children by reason of the rapidly increasing expansion of the towns and the growth of the population. The effect of exposure to sunlight on animal life is exceedingly invigorating, while the combination with the inhalation of salt-impregnated ozone-laden winds straight from the ocean, and redolent of the odour of the sea, is a most potent tonic for the sick. The seaside provides for the invalid and the growing child all that is manifestly so wanting in the habitations of the town dwellers, to whom change of air was not merely a luxury, but a vital necessity. A brief review of the various ailments for which seaside treatment is beneficial would include chiefly tuberculous disease of the bones, the joints, the lymph glands, and peritoneum and early phthisis. As a tonic after surgical operation and after recovery from exanthemata, sea air is most valuable. Cases well-nigh moribund from summer diarrhœa and entero-colitis derive the greatest benefit, and for rickets it is a most helpful adjunct. As regards the different seaside climates within a moderate train journey of London, there is, fortunately, a good choice. On the East Coast, in the counties of Essex, Suffolk, Norfolk—there are the towns of Clacton, Frinton, Walton, Dovercourt, Felixstowe, Aldburgh, Southwold, Lowestoft, Yarmouth, Happisburgh, Mundesley, Cromer, with its adjacent villages, Wells and Hunstanton, north of the Thames. South of of the Thames and in Kent there are Tankerton, Herne Bay, Birchington, Westgate, Margate, Broadstairs and Ramsgate. All of these are bracing, and eminently suited for the treatment of delicate children. In the winter and spring months these localities are rather too keen and east windswept for the safe treatment of lung and kidney affections.

Those for whom a bracing air is necessary can also find on the South Coast a suitable climate at Dover, Folkestone, Eastbourne and Brighton. But where a mild climate is indicated for those recovering from acute bronchitis, for those suffering from chronic bronchitis, and for convalescents from acute renal disease, rheumatic fever and heart disease, the choice should fall on Hastings, St. Leonards, Worthing, Littlehampton, or Bognor.

In the Isle of Wight, Sandown and Shanklin, on the East Coast, are bracing, while Ventnor, having a southern aspect, should be chosen for those who require a mild atmosphere. Owing to the latter town being built on terraces, cases of heart disease, with imperfect compensation, should not be sent there. On the other hand, cases of asthma may find a suitable climate at one of the different levels the town occupies. In the present remarks it is possible only to generalise, and it is out of the question, owing to the shortness of time at disposal, to review all the towns included in this definition, or to point out in detail any minor distinctions of climate between them.

The author was impressed by the fact that the physicians practising at the seaside do not make the best use of the natural advantages of their towns—viz., the sea water. In this respect they are behind their Continental brethren, and a trip to Biarritz, for instance, would make this abundantly clear to them. It is well known that hot and cold baths increase metabolism, while tepid baths produce no such effect. That metabolism is further increased by mechanical stimulation of the skin, such as by rubbing and by the addition of chemical substances, such as CO_2. In sea water the chemical stimulant resides in the various salts held in solution. Cold baths produce greater metabolic effects, because they lead to more muscular movements.

A further study is needed of the effects of hot and cold sea water baths and douches on the secretions and metabolic processes of children, and of the therapeutic effects of such remedies on their complaints, such as tuberculous adenitis, arthritis, tuberculous and rheumatoid, abdominal tuberculosis, and on various functional gastro-intestinal and liver complaints. The present custom is for the family doctor to send the sick child, with a relative or a nurse, to the seaside to recuperate as best it may, and the seaside physician never sees the patient unless it unfortunately happens to develop some acute ailment requiring the attention of a local medical man.

That arrangement can hardly be considered a satisfactory one. Would it not clearly be better that the seaside physician and the town physician should be brought more intimately into contact, and that a society, such as the British Balneological, should be the flux whereby the two could be brazed together? The former would thereby be afforded opportunity of teaching their town brethren what the seaside towns in which they resided were most suitable for, and what complaints should not be sent to them. At present it was left to the town physicians to find out for themselves what seaside climates are best suited to their juvenile patients. It is to be hoped that before many years have elapsed this will be remedied, and that in the future there will be found a little band of children's specialists well versed in sea-water practice at our important seaside towns, available, not only in the summer, but all the year round.

CLINICAL RECORDS.

CASE OF CHRONIC PHTHISIS: CALMETTE'S TEST.

By DAVID WALSH, M.D.Ed.,
Physician, Kensington General Hospital, &c.

E. H., female, æt. 38, domestic servant, came to hospital January 25th, 1908, complaining of chronic indigestion, which had become worse during the previous three weeks. Pain came on at once after food, and was associated with nausea, but seldom vomiting. There had been no hæmatemesis or melæna. Bowels regular. No cough.

Family History.—Father died at the age of 70 of "bronchitis," mother, at 43, cancer. Five brothers and sisters in good health; two died in infancy. An uncle on mother's side died of phthisis.

Previous History.—Was treated at Brompton Hospital for consumption five years ago. At the time she had grown thin, suffered from cough, and spat blood. After two years' treatment she "recovered," and was well for a time until an attack of pleurisy two years ago. Has had occasional attacks since of asthma and bronchitis.

Present Condition.—Is dyspeptic (as above noted); has got thinner of late; no cough; no hæmoptysis, but suffers from night sweats. Bronchial breathing was found over right apex; heart sounds feeble. No other marked physical signs in chest. Temperature at time of first visit, 98.4° F.; weight, 9st. 6lbs. A few weeks later patient complained of fleeting pain in right leg (so-called "tubercular rheumatism"). She was given a mixture of cod-liver oil and iron, and ordered a diet composed chiefly of fish and milk, with careful atention to exercise, clothing, and ventilation of bed-room.

(a) Abstract of paper read before the British Balneological and Climatological Society, March 5th, 1908.

Patient improved rapidly under treatment, and as there seemed to be some reasonable doubt about the activity of the tubercular process, a drop of .1 per cent. Calmette's suspension was introduced into the conjunctival sac of the right eye. A slight and delayed but positive reaction followed 13 hours later. This result may be regarded as indicating the activity of the tubercular process in some part of the lungs. The case was one in which it was not easy to form any definite opinion one way or the other. The patient's appearance certainly did not suggest chronic tuberculosis, nor was the diagnosis by any means so easy to arrive at as might perhaps be inferred from the foregoing history. Cough being absent, there was no sputum to examine for tubercle bacilli. Any additional evidence, therefore, as regards the activity of the tuberculous process has its value, even if we cannot accept such evidence as final in all cases.

The writer has to thank Dr. G. H. Jacob, House Surgeon, for careful notes of the case.

OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Syphilitic Ulceration of the Nasal Septum and Around the Anus.

BY PEYTON T. B. BEALE, F.R.C.S., F.R.C.P.LOND.,
Surgeon to King's College Hospital.

AMONGST Mr. Peyton Beale's out-patients was a man, æt. about 40, suffering from tertiary syphilis. When he presented himself it was observed that the septum between the two exterior nares, together with portions of the alæ nasi, were absent, and that the edges of the skin and mucous membrane were ulcerated. The appearance was like that which would have been formed by removing the portions with a large punching machine, the edges being sharp cut. The patient said he had difficulty in passing his motions, complaining of dragging pain when expelling fæces. He also said that he noticed discharge on his shirt. On examining the anal region, the anal aperture was found very deeply placed, the whole of the tissues for about two inches around it being lost, so that, on separating the nates, one saw a large cavernous circular opening about four inches in diameter, and about two inches deep, with a small, puckered ring of mucous membrane in the centre, this being the orifice of the rectum. He did not know how long the trouble had been going on; he did not even know that there was any ulceration present, the part being quite devoid of pain. Mr. Beale said that this was a condition brought about by gummatous infiltration; subcutaneous gummata arose in fibrous tissues such as fasciæ and intermuscular planes; also in connection with cartilages of the nose and muscular aponeuroses. They occurred in parts of the body which were not, as a rule, exposed to injury—for example, in the back between the scapulæ, the inner aspect of the nates and around the anus, the lower portion of the anterior abdominal wall over the symphysis pubis, below the inner head of the tibia. At the commencement there were one or more subcutaneous nodules, then later these coalesced, and the skin over them, as a rule, broke down fairly suddenly, the process being a sort of local necrosis, so that there was very extensive loss of tissue and of the skin covering it. It was fairly clear that there were two factors at work in causing the destruction of tissue—one an affection of the sensory and trophic nerves supplying the part, and the other an obliterative endarteritis of arterioles of the part. The process was devoid of pain and of hæmorrhage. He looked upon the condition as being the result of untreated or imperfectly treated syphilis. By that he meant that the patient's tissues had not received a sufficient amount of mercury or mercury in a form suitable for the tissues to destroy the syphilitic virus in them. He believed that in many cases of primary and secondary syphilis, in which large doses of mercury had been administered for a long period, the greater part of the drug in certain cases became deposited in some of the tissues either as an insoluble organic salt or in the metallic form. If in these cases iodide of potassium was freely administered, it produced iodide of mercury, and this was set free, rapidly causing symptoms of mercurialism to appear; in fact, many of the symptoms commonly ascribed to overdosage by potassium iodide were in reality due to the soluble mercury salt formed from the mercury stored up in the tissues.

The patient under observation was treated by subcutaneous injections of mercury, and locally with lotio nigra.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

OPERATION FOR SEPARATED LOWER EPIPHYSIS OF THE FEMUR—Mr. CARLESS operated on a boy, æt. 7, who had sustained a separation of the lower epiphysis of the femur a fortnight previously. The accident was the result of the practice so common among street urchins of running after a four-wheeled cab, jumping on to and sitting on the back springs. The patient's leg was caught between the spokes of the revolving wheel and wrenched forcibly forwards. The displacement of the epiphysis was, as is usual in these cases, in a forward direction. The limb was much swollen, and evidently a large hæmorrhagic extravasation had occurred, but there was no sign of pressure on the popliteal vessels. Attempts had been made then, under an anæsthetic, to reduce the displaced fragment; on one occasion, under the control of the X-rays, it was hoped that this had been satisfactorily accomplished, and the limb was put up in a flexed position, but the swelling of the leg was so great and the child was so restless that each time the fragment was found to have slipped forward after a day or two. It was therefore determined to fix the fragment by operation. A longitudinal incision was made on each side of the limb a little above the patella and carried down through the aponeurosis of the vastus on each side to the bone, the synovial membrane of the knee-joint being encroached on on the inner side; the margins of the fragment were then discovered and the periosteum divided—a raspatory was introduced under the fragment, which was levered up and loosened from the position in which it was becoming fixed. It was found, however, that the adhesions were so firm that its replacement was not to be easily accomplished without more space being obtained. The upper ends of the incision were therefore joined together by a curved out, and the body of the quadriceps entirely divided along this line. It was now possible to detach the fragments completely, and by means of traction on the lower part of the limb, combined with flexion of the knee, to bring the epiphysis into exact apposition with the lower end of the shaft. As soon, however, as the traction was relaxed the epiphysis slipped back into its old position, and therefore its fixation became a matter of necessity. This was accomplished by driving two steel round-headed nails, about two inches in length, through the epiphysis in an oblique direction into the lower end of the shaft, a sufficient length of these nails were left to protrude through the skin, one nail emerging through one of the incisions and a special opening being made in the base of the flap for the other. The joint was then closed, the quadriceps muscle sutured up with iodised catgut, and the skin incision closed without drainage. The limb was put up in a somewhat flexed position and kept at rest with a starch bandage. Mr. Carless commented on the difficulty he had experienced in the treatment of this case owing to the large amount of hæmorrhage extravasation. These cases, he said, were usually treated without much difficulty by putting the limb into a position of acute flexion, but in this case the smallness of the boy, his restlessness, and the impossibility of flexing the limb to any great extent owing to the swelling, rendered such treatment unsatisfactory, and therefore open operation had to be resorted to. If another similar case came under his observation he would not hesitate in the future to cut down at an earlier stage through the periosteum and let out the effused blood so as to facilitate the re-position of the fragment. The nails which had been introduced would be removed in ten days or a fortnight, and by that time, in all probability, the epiphysis would be secured in place.

The after history of this case has been satisfactory: the nails were removed in about ten days; the wound healed by first intention, and the epiphysis remained in good position. There was some difficulty in obtaining complete extension at first, but this is gradually being overcome by the use of a weight and pulley and massage.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, March 13th, 1908.

The President, E. H. Tweedy, in the Chair.

AN ABNORMAL PLACENTA.

Dr. Spencer Sheill exhibited an abnormal placenta which showed a raised ring forming a complete circle about half-way between the margin and the insertion of the cord, about 2 cm. in depth and half that in thickness. The membranes were adherent to the margin of the placenta. On cutting into the placenta —at the suggestion of the President—he found that the membranes below the ridge met, but did not cause a complete folding of the layers. He would, however, submit the specimen for a closer examination to a pathologist.

A NEW TABLE FOR ESTIMATING THE DATE OF DELIVERY FROM THE SIZE OF THE UTERUS.

Dr. **Henry Jellett** exhibited the above. It was not, he said, intended for perfect accuracy, nor was it new. It was simply an arrangement of ordinary data to save time in calculating the date of delivery, as estimated by the size of the uterus, in cases in which the patient could not give a definite menstrual history.

Sir A. V. Macan, Professor Alfred Smith, Dr. Purefoy, and the President spoke.

TUBERCULOUS SALPINGITIS.

Dr. R. D. **Purefoy** read a paper entitled: "Some Remarks on Tuberculous Salpingitis," with specimen illustrating the condition. We hope to publish this paper in our next issue. In the discussion that followed:—

Sir A. V. **Macan** said there was a great difficulty as to the origin of primary tubercle of the tubes. If it did not ascend or descend they could only suppose that it filtered out from the blood. Sterility was one of the earliest effects of tubercle of the tubes, and he was not sure whether it would be much use to leave a small portion of the tube in such cases. He had at one time held the view that if they could not see their way to extirpate completely such affection of the tubes they had better leave them alone, but now he thought they ought to remove as much as was possible, and trust to general strength to get rid of what was left behind.

Professor **Alfred Smith** said they were struck, in operation, with the fact that it was of little use to leave even a small portion of a Fallopian tube behind; the tube became so thickened that the lumen was practically useless, and seemed to be another starting focus of disease. But, when the tubes were removed, it did not follow that the uterus should be removed also. If it was curetted, it would probably be found to contain no tuberculous disease. While, however, no necessity might arise for the removal of the uterus in tubercular salpingitis, it might be good practice to remove it in staphylococcic or streptococcic infection. As regards drainage, he was of opinion that it was not necessary to leave in a tube or gauze-drain; by leaving them in they courted the tendency to a hernia in the track left by the drainage tube.

Dr. **Spencer Sheill** said he had under his care a case of suspected tubercular salpingitis in which intermittent diarrhœa was a marked symptom, and without, so far as he knew, any disease of the intestines. He asked if Dr. Purefoy had found this to be a usual symptom of tuberculous disease of the tubes.

Dr. **Jellett** said that, a few years ago, Dr. Bond, of Leicester, had brought to the notice of the annual meeting of the British Medical Association the existence of what he called "ascending mucous currents," and showed how methyl blue, deposited in the region of the vagina, was found afterwards in the tubes. This suggested one mode of origin of primary tubal tuberculosis. The infection had to pass through the uterus, the periodical sweep out of which probably prevented it from takng root there. He was strongly against the wholesale removal of the uterus and ovaries in these cases. Tuberculosis of the ovaries was a very rare condition, and he thought that, even if there were adhesions round the ovary connecting it with the tube, where at all possible, one or both ovaries should be spared; and the same thing applied to the uterus. Drainage might be very necessary in some cases, but he would drain through the vagina, and in cases in which there was no intestinal infection of the tube contents he would not drain at all.

Dr. **Holmes** said he had lately seen several cases where tubercle was suspected, where the Calmette reaction was tried, and three out of four reacted, and evidently the condition was very early.

The **President** said it was very rare that tuberculous tubes were diagnosed until they had opened the abdomen, and they did not always recognise it even then. He agreed with the wisdom of draining in Dr. Purefoy's case, and he considered the best plan to be a wick of iodoform gauze through the abdomen rather than through the vagina. He drained more with the hope of exciting a localised peritonitis than getting septic matter away. The cause being walled off would prevent the infected area spreading, and they had an outlet for any infected matter. He did not think there was anything in the fear of a hernia forming. His experience as regards leaving the ovaries and tubes was not at all that of Professor Smith's. Dr. Jellett had pointed out that it was very rare to see tubercular tubes affecting the uterus; but they sometimes saw, just at the cornua, an isolated tubercle which they could cut out, and leave a healthy tube behind. If, however, the tubes were removed, he did not see the use of the uterus, if for no other reason than that women were more subject to cancer than men, and that the uterus was the organ most prone to that disease.

Dr. **Purefoy**, in reply, said he agreed as to the wisdom of avoiding drainage, except for some good reason, such as he thought he had in the case before them. He was also in accord with regard to the retention of the ovaries where possible. He thought it was quite possible that diarrhœa was a sign of tuberculosis, but he had not had the condition under observation.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, March 12th, 1908.

On opening the meeting, the **President** alluded to the loss the Institution had sustained by the deaths of Mr. Edward R. Bickersteth and Mr. Reginald Harrison. Mr. Bickersteth was the oldest existing member, having joined in 1853. In 1870 he was elected President. He was a member of the distinguished family of that name, and, in addition to his eminent surgical skill, which has been so well described elsewhere, he possessed the true medical instinct in dealing with his patients. His manner and address were models for younger men, for he possessed in the highest degree the power of acquiring the confidence of his patients. Mr. Reginald Harrison was one of our oldest surviving members, and was President in 1880-1881. To his genius in his management of the Liverpool Medical School is to be attributed the revival and progress which have led to its present status. Mr. Harrison established for himself a reputation in the treatment of urinary affections, and when he removed to London the profession in Liverpool felt that they had lost one of their most capable members.

A PURE MILK SUPPLY.

Dr. H. **Clarke** moved the following resolution:—"That a committee of five members, with power to add to their number, be appointed to consider whether the Liverpool voluntary hospitals should be advised to take action to ensure the greater purity of their milk supply, with special reference to tubercular infection, and to report thereon to the Medical Institution." He pointed out the extent of the danger, about 5 per cent. of all milk sold in Liverpool being tuberculous. This danger could be removed by sterilising all milk used. This method, however, was unsatisfactory. The milk of a diseased cow should not be used for food if it could be avoided. The efforts of the public health authorities had resulted in a marked improvement in the milk produced in the Liverpool area, but their powers over outside dairies which supplied most of the hospitals were inadequate, and, in consequence, no improvement had taken place in the quality of the milk from the country during the last ten years. He pointed out that there was no adequate body of public opinion to support the authorities against the strong opposition drastic measures were sure to arouse, and he considered it was the duty of the medical profession of Liverpool to give a clear and authoritative statement of the present state of our knowledge of this subject, and to show by a practical demonstration how this danger could be avoided. In this way public opinion could be educated, and the efforts of the authorities rendered easier.

The resolution was seconded by Dr. C. Hill, supported by Drs. P. Marsh and Logan, and carried.

The following gentlemen were selected to serve on the Committee:—Mr. T. H. Bickerton (President), Sir Rubert Boyce, Drs. H. Clarke, P. Marsh, E. E. Glynn, E. Hope, C. Hill, W. B. Warrington, and R. J. M. Buchanan.

OPHTHALMIA NEONATORUM.

Dr. **Nimmo Walker** read a note on ophthalmia neonatorum based upon an experiment in its treatment which he believed to be new—at any rate in Britain. A small ward had been allotted in St. Paul's Hospital, and, with the help of the City Health Department, acting under the "Notification of Births" and "Registration of Midwives" Acts, infant and mother were admitted at the beginning of the disease. He hopes to publish fuller details and particulars later.

Dr. **Stookes** pointed out that the midwives trained during the last ten years had been thoroughly impressed with the importance of cleansing the child's eyes. At the Liverpool school the midwives were taught the details of asepsis, but he did not think it would be wise to allow midwives to use antiseptics on their own initiative. He recommended Dr. Walker to notify every case he met with of neglected ophthalmia to the supervising authority appointed by the Central Midwives Board.

Dr. **Grossmann** was heartily in sympathy with Mr. Walker's suggestions. The movement was one which required a good deal of perseverance to produce tangible results. In a paper which he had read at the British Medical Association at Leeds twenty years ago, Dr. Grossmann had emphasised the fact that the disease was one which came almost invariably under the range of the obstetrician; when it came to the ophthalmic surgeon the mischief had nearly always been done. Inasmuch as it was a thoroughly preventible disease, there was no excuse for its occurrence at all, and the fact that about one-third of the inmates of the blind asylums owe their blindness to this ophthalmia is a crying disgrace to existing conditions, as we have absolutely reliable methods for its prevention.

The subject was further discussed by the President, Drs. Logan, Stockdale, Harcourt, E. Stevenson; and Mr. Walker replied.

A discussion then took place on the

PATHOLOGY AND TREATMENT OF EXOPHTHALMIC GOITRE.

The discussion was opened by Dr. W. B. **Warrington**, who said that, owing to the general advance that had taken place in our knowledge of thyroid pathology, the present was an appropriate time to reconsider the treatment of Graves' disease. He briefly reviewed the views held as to the functions of the thyroid and parathyroid bodies. He stated the necessity for greater knowledge of the history of the whole course of the disease, and said that, in his opinion, it was a very serious condition, only rarely terminating in real and permanent recovery. He described the principles underlying the serum and general treatment of the disease, and alluded to the remarkable successes obtained on the Continent and America from operative procedure.

Dr. A. **Gordon Gullan** discussed the etiology of Graves' disease, and showed that it was more prevalent in women, being rare before puberty and after the menopause, and mentioned instances of family history in this disease. He then dealt with the pathology of the disease, and claimed that it was due to excessive activity of the thyroid gland—thyroidism—as proved by experiments on animals and over-dosage with thyroid extract in man. He also discussed the *rationale* of the action of anti-thyroidin (mœbius), radogen and thyroidectin. He quoted several cases which he had treated during the last few years with these substances, and in most instances the results were most satisfactory, and in many cases the result was quite definite. In conclusion, he urged a more extended use of anti-thyroid treatment rather than operative treatment, and advocated that larger doses of the antithyroid substance should be used in some cases.

Dr. T. R. **Glynn** pointed out that Graves' disease was hereditary. He had met with an instance where two sisters and the only daughter of one of them suffered from this affection. In the case of the latter the typical symptoms appeared at the age of six. The majority of these cases improved under rest and treatment in hospital, and occasionally recovered perfectly. The mortality of thyroidectomy had diminished greatly in late years, but thyroidectomy and other operative measures were only moderately successful. In a recent paper by Dr. Garre, of Bonn, he stated that he had operated on 35 cases of Graves' disease chiefly by removal of the more hypertrophied part of the gland. Absolute cure had followed in 16 per cent. only, amelioration in 85, and no improvement in 15 per cent., deaths in 12 per cent. He also referred to the fact that in fatal cases the thymus was enlarged in about 80 per cent., indicating that there was some relation between this gland and the thyroid.

Mr. C. **Thurstan Holland** discussed the X-ray treatment. Twenty cases had been treated in private, and at the Royal Infirmary, during the last five years, but some of these only attended a few times. In most of the cases following immediately on the first exposure a noticeable drop in the pulse rate occurred, and muscular tremors and general nervous symptoms abated. Several mild cases after a course of this treatment were symptomatically cured. The X-ray treatment seemed to be of undoubted value, and in bad cases might be valuable as a preliminary to operative interference. In making the exposure the skin should be protected by two or three layers of thick boiler felt.

Dr. R. J. M. **Buchanan**, while agreeing that the symptoms of Graves' disease were due to an increased or perverted activity of the thyroid gland, did not consider that much light had been thrown on the cause of this. He pointed out that as the other organs of different people varied in the range and character of their activity, so it is with the thyroid, and that the condition is a congenital anomaly in certain individuals. During his investigations into the clinical side of the disease, he had been led to conclude that the condition is one largely governed by heredity. He considered that people in whom Graves' disease showed itself in later life were of a separate and distinctive class, and whom he believed had the affection in a certain degree from early childhood. A condition which might be regarded as simple goître if closely watched will be found to develop some sign of the graver form at some period of life. He showed lantern slide photographs of families of the type to which he referred, and in which some members had simple goître, others in the same family the symptoms of Graves' disease. In one family the father had a large thyroid, and the condition had been transmitted to his three daughters by two separate mothers, two of the daughters had large quiescent thyroids, and the third a large thyroid with signs of Graves' disease. In one case he had watched the development of the disease in a lady over a period of 18 years, and also in her daughter from early childhood for the same period of time. He considered the thyroid functionated intermittently as all other organs of the body must do, and in this way they account for the exacerbations which are so common. Dr. Buchanan drew attention to a clinical sign which he had found present in cases of Graves' disease, and which he had not seen described, that before moving the eyes from one fixed object to another blinking of the eyelids always took place.

The President, Drs. Abram and Johnson, and Messrs. F. T. Paul and Damer Harrisson also took part in the discussion.

ULSTER MEDICAL SOCIETY.

Meeting held Thursday, March 26th.

The President, Dr. John McCaw, in the Chair.

A very large number of specimens of various sorts were on exhibition before the meeting, and various demonstrations were given.

Prof. Symington gave a lantern demonstration of (*a*) a reconstruction to illustrate the relation of the deeper parts of the brain to the lateral aspect of the skull; (*b*) specimens illustrating dental anatomy with X-ray photographs of developing teeth, by Dr. Rankin. These radiographs, shown on the lantern screen, showed in a most beautiful manner the position of the teeth, both milk and permanent, at various ages from birth onwards.

Dr. **Crumble** gave a lantern deuonstration of the variations of the central or Rolandic fissure of the cerebrum, as noted in a large number of specimens in the anatomical rooms.

Drs. **Killen** and **Maguire** showed specimens of spinal cord and hind-brain to illustrate the order of medullation of the fibres.

Professor **Milroy** read a short communication on Colour Fatigue, and showed apparatus used in testing it.

Professor **Summers** and Dr. **Wilson** presented notes on four subjects:—

(*a*) Agglutination of organisms of the typhoid, colon and alkaligenes groups by the blood-serum of cerebro-spinal fever cases.

(*b*) Cerebro-spinal meningitis, due to infection with the typhoid bacillus, Gartner's bacillus, and the anthrax bacillus.

(*c*) Fermentative powers of the meningococcus and gonococcus.

(*d*) Certain differences between young and old cultures of meningococci.

These notes were of too technical a nature to lend themselves to condensed reporting, but will, no doubt, be published in full later.

Drs. D. P. **Gaussen** and **Houston** gave an account of a case of streptococcic septicæmia treated by a vaccine. The patient, a lady, was ill for many weeks, with frequent rigors, and temperature running up to 104°. A bacteriological examination by Dr. Houston showed that a streptococcus was present, and a vaccine prepared from cultures of this was administered six times, at intervals of a few days, with most satisfactory results.

Sir John **Byers** showed a number of specimens of gynæcological interest, including a molluscum fibrosum tumour removed from the clitoris, and a large tumour of rapid growth, the size of a full-term fœtus, which was removed from the abdomen without any vessels having to be tied, and which showed no trace of connection with uterus, ovaries, or any other structures. Its structure was doubtful—seemingly muscular, but with some signs of malignancy.

Dr. **Cecil Shaw** showed (*a*) a water-colour drawing of a peculiar congenital condition, melaena of the conjunctiva, and a microscopic section of a piece of the same. (*b*) A series of sections illustrating different forms of nasal neoplasms. In reference to the former specimen, Dr. Shaw said that he had been unable to find any description of a similar condition in ophthalmic literature. The patient, a man, æt. 40, had six or eight small sessile tumours, nearly as large as a split pea, scattered over the conjunctiva of the lid and globe in one eye only, and a good deal of pigment diffused through the surrounding conjunctiva. The eye was otherwise normal.

Mr. **Craig** showed an eye removed for melanotic sarcoma of the choroid.

Mr. **Fullerton** showed several specimens and instruments illustrating recent advances in the surgery of the bladder.

Specimens were also shown by Drs. St. George, Darling, Dempsey, O'Doherty, and Messrs. Mitchell, Kirk and R. J. Johnstone.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, March 29th, 1908.

Cardiac Pleurisy.

Leaving aside pleural effusions due to tuberculosis, cancer, and certain acute infectious maladies, it is common practice to find pleurisy in patients suffering from cardiac and renal disease as well as from arteriosclerosis. To these effusions are given the names of pleurisy or hydrothorax, according as they are unilateral or bilateral. The former were particularly studied by Huchard, Merklen, Renon, etc., who proved their frequency on the right side and insisted on the importance of thoracentesis as treatment.

The inflammation of the pleura is unilateral, says M. Renon, and is accompanied by a fibrous exudation and false membranes. The liquid is either purulent, hæmorrhagic, or sero-fibrinous. It depends entirely on pulmonary infarctus and frequently lobular apoplexy is evident; pain, more or less intense, with sanguinolent expectoration, precedes by one or several days the development of the effusion. Sometimes, however, the symptoms are less acute, the pain is insignificant, but dyspnœa is very pronounced.

Cardiac pleurisy varies considerably as to its situation. It can occupy the whole cavity of the pleura, or it can be supra-diaphragmatic, mediastinal, or encysted. The commencement is slow and insidious. The physical signs present the usual characters. The exciting causes are generally pericarditis, hepatic congestion, acute œdema of the lung.

As soon as the existence of the effusion is diagnosed, it should be evacuated without delay, and this repeated frequently if necessary. The operation should be done low down (tenth intercostal space). Immediately the liquid is evacuated improvement takes place, the dyspnœa diminishes, sleep returns, and polyuria takes place.

Nucleinate of Soda.

Nucleinate of soda administered in major abdominal operations seems to have a double action, a preventive local action on peritoneal infection, and a general action by which the defences of the organism are increased, phagocytosis in particular.

When injections of 10 grains in an ounce and a half of serum are made in the external portion of the thigh one or two days before the operation, no inflammatory reaction follows the operation. The same amount abandoned in the abdominal cavity produces similar effects. Thus, nucleinate of soda can be injected beneath the skin the day before the operation, or poured directly into the peritoneal cavity before closing the wound at the dose of 10 grains, and under its influence the normal temperature returns on the third or fourth day.

Thiosinamine and Deafness.

Deafness, as a rule, is due to three great causes—disease of the labyrinth (ischæmia followed by arterial sclerosis), oto-sclerosis, and adhesive otitis.

The first-named is observed in persons over fifty suffering from arterio-sclerosis generally, and in whom local treatment is useless.

The second is found in the young—young women principally. The deafness comes on insidiously, progresses at each pregnancy, and is complete towards forty-five.

The lesion is deep-seated. On the confines of the labyrinth hyperostosis accumulates in the labyrinth, obstructing the foramen, and paralysing the terminal filaments of the facial nerve. No therapeutic treatment, local or general, has any effect on the development of the malady.

The third or adhesive otitis is of purely local origin. The infection ascends the nose and the naso-pharynx by the Eustachian tube, attacks the middle ear, either suddenly in the form of suppurative otitis or insidiously by repeated catarrh. Otorrhœa leaves behind cicatrices of the tympanum, while catarrh provokes progressive hyperplastic otitis which deforms the drum and welds together the small bones. Here local treatment succeeds.

Besides the complicated and varied interventions of aurists, who endeavour to remove the fibrous obstacles to audition, a new treatment has been proposed and practised by M. Lermoyez, which, he maintains, is as simple as effective: thiosinamine.

Von Hebra introduced thiosinamine into therapeutics, and its indications extended rapidly. Unna used it with advantage in cheloids. Latzko employed it in pelvi-peritonitis, while Teleky obtained very good results in applying it methodically in the treatment of fibrous stricture of the œsophagas.

The cases published by Teleky gave to M. Lermoyez the idea of employing thiosinamine in cicatricial or catarrhal otitis. The treatment is simple enough and can be employed by any practitioner. The patient bathes his ear every evening with a warm solution of thiosinamine and antipyrine for five minutes, and twice a week he goes to see his medical attendant, who practises pneumatic massage of the tympanum. In general, at the end of a fortnight, the hearing is much improved. This improvement is very remarkable where a large perforation of the tympanum permits the penetration of the liquid into the internal ear.

Ichthyosis.

Ichthyosis should be considered more in the light of an infirmity than of a malady. If no treatment has any curative effect, considerable improvement may be obtained by simple means.

Three or four times a week, the patient suffering from ichthyosis, takes a prolonged bath, during which he rubs himself with ordinary soap; after this he applies a small quantity of glycerine.

The skin is thus modified very rapidly, especially if the cutaneous secretion—perspiration—is stimulated. The general treatment includes cod-liver oil and arsenical preparations.

GERMANY.

Berlin, March 29th, 1908.

At the Verein für Innere Medizin, Geheimrat Prof. Bumm spoke on

Pulmonary Tuberculosis and Gravidity.

He said that the indications to interrupt pregnancy in women suffering from pulmonary phthisis had become very frequent of late. Numerous tuberculous women were sent from curative institutions, and the Charité for this purpose. That pregnancy reduced the resisting power of tuberculous women, that the disease advanced rapidly in that condition, and first showed itself then when it had before been latent was already known. For that reason it had been demanded that tuberculous girls, and those of tuberculous parentage should not marry, they should not at least have children, or not suckle them. Whilst the latter requirement was easy of fulfilment, we were powerless as regarded the others. The question therefore frequently came up: Shall we interrupt the pregnancies of tuberculous females? No general principles could be laid down, we must individualise, and decide each case by itself. In thus judging, however, we must lay down some guiding principles:—1. Our hopes from the operation must not be too great. 2. We must undertake the interruption only when objective signs of the disease are actually present, not from fear or because of hereditary tendency—there we lost the ground under our feet. Sometimes the interruption was wished for on other grounds—for that we could not be responsible. 3. The operation should never be undertaken in advanced cases, for here there was no hope of improving the patient's condition, but it was almost always made worse rapidly from the loss of blood and other fluids. An exception was formed as an *indicatio vitalis*, by sudden excessive œdema of the lungs, the speaker had seen instances of such rare cases several times. 4. The interruption should not be made in advanced pregnancy, as then the loss of blood and fluids was greater, and the disease was made rapidly worse by it. The operation was not indicated therefore in half the cases of pregnancy, and only in pronounced, but not too far advanced cases of tuberculosis.

His experiences with the ophthalmic reaction had been very good, if the result was negative the progress was almost always rapid. It also happened sometimes that after the interruption the reaction again became positive, a certain sign that the tuberculosis was improved. (A case of this kind was shown.) The operation was to be performed at one sitting under lumbar anæsthesia. The doing of it in stages after preparation and dilatation was objectionable, on account of the greater losses of fluid and the depressing mental effects of the prolonged course of procedures.

Sometimes no advance was made with a simple interruption as a second pregnancy immediately followed, in such cases it was sometimes advisable to sterilise at the same time the abortion was induced, by removing the ovaries along with the pregnant uterus. The consideration that a change for the good might be brought about by arrest of the menstrual flow, might lead to a favourable view of the proposal for sterilisation. Naturally this could only be done in the cases of women who already had children, and who gave their consent. Naturally also the cases must be carefully selected.

Geheimrat Prof. Hildebrand related a case of

Œsophageal Bodies with Gangrene of the Lung —Operation and Recovery.

In January, 1907, the patient, a female, swallowed a plate with artificial teeth in the night. She had sought relief from many medical men without obtaining any. In November, *i.e.*, 10 months after the accident she was admitted into Kraus's Klinik, and here the position of the plate was ascertained by means of the X-rays to be just above the cardiac opening. The patient was then transferred to the speaker's wards in a most reduced condition. From the situation it was not possible to extract the foreign body through the mouth. He performed laparotomy, and made a small opening into the stomach; he could now feel the body with the tip of his finger but not grasp it, nor could he do so even by passing the whole hand into the stomach. Neither could he grasp it with a pair of forceps, as it lay embedded in a cavity, near to the heart, and only separated from it by a thin wall. He now made an incision into the œsophagus from the neck, and even then he did not succeed. It was only after breaking up the foreign body with a powerful pair of forceps that he was able to extract it, piece by piece. After the removal gastrotomy was performed for the purpose of giving nourishment. At first all went well, and then fever set in, with fœtid expectoration, from an encapsuled empyæma and pulmonary gangrene. All went well in the end, however, and the patient had gained 24 lbs. in weight in three months.

The wound of the œsophagus healed *per primam* as it was not used for feeding. The gangrene of the lung recovered after draining.

The *Therapeutische Monats. XXI.* contains a paper by Dr. A. Lübbert, of Hamburg, on

The Treatment of Hyperæmia.

After speaking of the usual methods in vogue, Preissnitz bandages, mud and peat baths, poultices, etc., he refers to the more recently introduced method of Bier, which as every one now knows consists in the production of an artificial hyperæmia by means of elastic bandages, cupping glasses, or exhausts made of indiarubber. "Realising" some of the difficulties met with in the employment of the Bier method, and endeavouring to find out one by which they could be overcome he thought that some hygroscopic application would answer the purpose. When a friend suggested the American preparation called "antiphlogistine," and after he had satisfied himself from its composition that it would be likely to be useful he gave it a trial. To his great satisfaction it seemed to answer all the requirements exactly. It extracted a large quantity of fluid without leaving the skin in the sodden condition so regularly seen after poultices. It relieved pain promptly, and it possessed the distinct advantages that it was easily applied, did not require frequent renewals, and gave notice itself when it had done its work by turning up at the edges and becoming loose. The paper concludes with reports of a number of cases in which it gave satisfaction.

AUSTRIA.

Vienna, March 29th, 1908.

Polyarticular Arthritis Deformans.

Wick treated the Gesellschaft to an exhaustive exposition of Heberden's nodules, or what others have termed polyarticular arthritis deformans. These nodules usually begin to form about the last phalangeal articulation in advanced years, or about the age of 40 in females and 60 in males. As time rolls on the interphalangeal joints become involved. They appear without pain or inflammation and are evidently excrescences of bone. Their etiology seems closely connected with the climacteric period, sterility, or senility. Such patients exhibit general and local nervous phenomena, which he considers factors in their production. He is quite convinced the nodules are not gouty in nature, nor are they connected with arthritis deformans of the large joints, although they may have some connection with chronic rheumatic arthritis.

Noorden is of the same opinion that this morbid condition is not gouty, but thinks the disease might be designated arthrosis deformans. He is also of opinion that there is some connection between the malady and the sexual organs.

The treatment can only be symptomatic from our present knowledge; hence hot baths, sand electric baths, or Biers' congestive treatment are found to be the best. Paraffin injections have proved successful in many cases where the joint is implicated.

Weichselbaum thinks that the name Heberden's nodules should be retained for the disease, as it is a specific one and worthy of further investigation.

Pineles said he had often seen Heberden's disease appear after castration of both women and men; in the latter he thought the connection was well established.

Gara thought Noorden's treatment with vaseline injections was a very temporary remedy and hardly worth the effort, as the injections were absorbed within a week.

Pyocyanase.

Winkler gave a biological demonstration of the above, which acts on the polynuclear leucocytes, dissolving the plasma, leaving nothing but the nucleolus and granula. With the condenser these active granulæ are observed to become quiet when pyocyanase is presented, and the amœboid movement of the cell ceased at once. Spirilla and bacteria shared the same fate as the leucocyte, which became quite stiff. The spirochæta pallida and spirillum volutans were acted on in the same manner and with the same result. The spermatozoa were the principal object of research; they were acted on in a dark field and not, as is usually done, with the microscope. A very brief period was necessary to check the action of the spermatozoon. In the gonorrhœal discharge the granulæ and the gonococci stood out boldly on the slide when examined in the ordinary way; and after an hour the whole became solvent. If this pus be coloured with neutral red methylen blue and the pyocyanase be applied for five minutes, the gonococci will be found to be dead. A strong feature of the experiments was the absence of any action on the epithelial cells. Unna tells us he dialysed and washed out the granula with sodium chloride, but Winkler never obtained this result with the drug.

Weinberger gave a report of his results obtained from pyocyanase on the coli and typhus bacterium, which were much the same as Winkler's.

Fellner rose and extolled the clinical effects of pyocyanase, which he has used in cases of gonorrhœa with wonderful success. The gonococci disappear from the secretions of uterus and urethra in a very short time, while the subjective symptoms are instantly relieved.

Fibrolysin.

Gara followed with a history of seven cases of ankylosis which he had treated with success. The pathological fibrous tissue becomes softened under the influence of intra-muscular injections of 2 gr. of fibrolysin daily. Gonorrhœic and rheumatic cases yield readily to this treatment. Manual or machine extension commences shortly after beginning the injections, and if they be troublesome a little aspirin relieves the difficulty. Two of his cases which had both knees and hips bent, could after 17 injections move them through 90°. In others the elbows were movable to the same extent after 17 injections.

Teleky related how he had succeeded, eight years ago, with thiosinamine in relieving a stricture in the œsophagus which was the result of a cicatrix. Since that time he had administered the same drug for other forms of ankylosis in joints with equal success. Parts long stiffened with bandages, instruments, etc., are rapidly relieved. He had not yet tried it in rheumatic joints.

Wick has also used fibrolysin in rheumatic ankylosis without success, but would not condemn the drug with such scant knowledge.

Ullmann had used both fibrolysin and thiosinamine in a hundred cases of cicatrices, leucoma, scleroderma, etc., etc., with decided improvement of the patient. Thiosinamine first and fibrolysin afterwards act very well.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Retirement of Professor Crum Brown.—Professor Crum Brown, who for forty years has occupied the Chair of Chemistry in the University of Edinburgh, is about to retire from his position. He comes of a well-known Edinburgh family, and to his brother, the late Dr. John Brown, the world owes "Rab and his Friends." Professor Crum Brown received his M.D. degree in 1861. He studied chemistry under Gregory and Lyon Playfair, and then under Bunsen and Kolbe, and in 1863 began the career of an extramural lecturer. On the election of Sir Lyon Playfair as member of Parliament for Edinburgh and St. Andrews Universities, Crum Brown became Professor of Chemistry in the year 1869, and since then has occupied a leading place in the scientific life of Edinburgh. It has been said of him that he is capable of examining in almost any of the subjects of the scientific curricula in the University, and certain it is that few of the members of the Senatus Academicus are more versatile than Crum Brown. His thesis of 1861 anticipated many of the later discoveries on structural chemistry, but as it was not published until 1878, he never, perhaps, has received full credit for his investigations. The system of graphic formulæ described in it is that now universally followed. The researches by which Crum Brown is best known encroach upon the domain of physiology and pharmacology. In 1868, in conjunction with Sir Thomas Fraser, he made an important investigation into the chemical constitution of the alkaloids, and the now well-known fact established then—namely, the effect of the introduction of the methyl group—was the first serious advance in our knowledge of the relation of chemical constitution and pharmacological action. For this the authors were awarded the Macdougall-Brisbane medal of the Royal Society of Edinburgh, while in 1875 Professor Crum Brown received the Keith prize for his researches on the functions of the semi-circular canals, in which he demonstrated the nature of the stimulus to which they respond—namely, stresses in the endolymph. Professor Crum Brown is also a mathematician and a linguist. His knowledge of languages extends to Russian and Chinese. In his public capacity Crum Brown has not shirked such duties as have naturally presented themselves to one in his position, but he has never put himself prominently forward in such matters. He has been a manager of the Royal Infirmary, and a member of the School Board. He has devoted himself almost exclusively to science, and has for many years been Secretary of the Royal Society of Edinburgh, in the debates of which body he takes an active part. He is a Fellow of the Royal Society, and LL.D. Glasgow, and was Boyle Lecturer at Oxford in 1895. Coming, as he does, of an ecclesiastical stock, it is not to be wondered at that Professor Crum Brown takes an ardent interest in Church matters, both on the historical side and in the everyday affairs of Church life, and many are the stories of his kindliness and charity in connection with congregational work. He is hale and alert, and his clear eye and vivacious gesture belie his seventy years. He retires from the University with his faculties undimmed, respected and beloved by colleagues and students.

GLASGOW INFIRMARY.—FINANCIAL IRREGULARITIES.—Mr. Henry Lamond, who was for forty years secretary to the Infirmary, having resigned that office a month ago, and his partner, Mr. J. S. Lang, were arrested last week on a charge of embezzlement. Messrs. Lamond and Lang were lawyers in Glasgow, and the charge on which they were arrested arises in connection with a sum of £10,000 of trust funds, the life rent of which was payable to certain beneficiaries, and on their death the capital sum was to be paid to the Infirmary. Bail was fixed at £2,000 in each case, and as the sum was not forthcoming, the accused were conveyed to prison. Mr. Henry Lamond is over 70 years of age, and had been a member of the Partick Town Council and served as a magistrate. The alleged irregularities have been going on, it is stated, for the past fifteen years.

LIEUT.-COL. W. B. BANNERMAN, M.D., ON PLAGUE.—An address on recent researches into the etiology of plague in India was delivered by Col. Bannerman, of the Indian Medical Service, at a special meeting of the Medico-Chirurgical Society in Edinburgh last week. He described the appointment and *personnel* of the Commission, which began work in 1905 at the Bombay bacteriological laboratory at Parel and in the Punjaub. In that year the existing knowledge of plague was confined to two types of the disease—pneumonic, which is very contagious from one person to another, and bubonic, which is not communicable. In fact, it used to be said that the safest place in a plague epidemic was the ward of a plague hospital among bubonic cases. It was further known that there was a marked seasonal prevalence of plague, which differed in different towns, each locality having its own epidemic season. It had also been observed that houses, not inhabitants, were infective, and there was some evidence that rats played a part in carrying the disease. If curves of mortality were made, it was found that the discovery of dead rats always preceded the rise in the human death-rate. It had also been shown that the transmission of infected clothes to distant localities might give rise to fresh outbreaks. In the opinion of the First Plague Commission, infection is almost always conveyed through the skin, but "suctorial insects do not come under consideration in connection with the spread of plague." Captain Liston, however, had made an elaborate series of researches showing that plague was actually communicated to man from rats by fleas. There were three species of rats in India, the two most common being the black and the brown rat. Liston showed that the fleas of rats and men belonged to different species, and that the former would attack other animals and man himself in the absence of their natural host. He also said that guinea-pigs could be used to trap rat fleas in a plague-infected place, and that these rat fleas sometimes had plague germs in their stomachs. Guinea-pigs, in places that were not plague-infected, had no fleas on them, and did not die of plague, as did some of those exposed to the bites of rat fleas. Finally, he showed that in plague-infected houses a large proportion of the fleas taken on men were rat fleas, not human ones. Three possibilities presented themselves to the 1905 Commission:—(*a*) Rats might soil food by their excreta; (*b*) rats might similarly contaminate the floors; (*c*) some insect on the rat might convey the bacillus. The last of these was finally accepted as fully accounting for the epidemiology of plague. The general conclusions arrived at were:—(1) Pneumonic plague is highly contagious, but, being rare (less than 3 per cent. of all cases), plays a very small part in spreading the disease; (2) bubonic plague in man is not infectious, and is entirely dependent on the disease in the rat; (3) the infection is conveyed from rat to rat, and from rat to man, solely by the rat flea; (4) a large majority of plague cases occur singly in houses, but when more than one case takes place in a room, the attacks are usually nearly simultaneous; (5) plague is usually conveyed from place to place by rat fleas brought by people in their baggage or on their person. Colonel Bannerman's interesting address was illustrated by many lantern slides showing the conditions under which the Indians are housed and the facilities they offer for invasion by rats, as well as photographs of the experimental station and the researches in progress. It was fully appreciated by the members, as was shown by the large attendance.

BELFAST.

ROYAL VICTORIA HOSPITAL.—The annual meeting of this hospital was held last week, the Bishop of Down, Connor and Dromore presiding. The report showed that the intern patients last year numbered 3,281, and the extern 29,433. The average number of beds occupied was 223. Dr. McKisack moved the adoption of the medical report, and referred to the great loss the hospital had sustained in the retirement from active duty of Dr. Nelson, so long the senior ophthalmic surgeon to the hospital.

SAMARITAN HOSPITAL.—The Lord Mayor presided over the annual meeting of this hospital last week, when Dr. Hicks read the medical report. This showed that 200 intern and 683 extern patients had been treated during the year, and 149 operations had been performed, with four deaths. Hitherto there has been a minimum fee of 10s. per week for intern patients, but the medical staff have now suggested that this is a prohibitive charge to many women of the working classes, and have asked the Board to arrange for a varying charge, to be fixed by the Ladies' Committee after inquiry into the circumstances of the case.

PUBLIC HEALTH.—The death-rate for the city still remains abnormally high, having been 26.9 last week. No less than 12.6 of this was due to chest affections, a figure 5.6 in excess of the normal. The zymotic rate was 2.6, chiefly from measles and whooping-cough. There are nine cases of typhus in Purdysburn Fever Hospital, and 30 contact cases in isolation at the Twin Islands. There are still 20 cases of cerebro-spinal meningitis in hospital.

LETTERS TO THE EDITOR.

THE REFERENDUM OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter of your correspondent who signs himself "An Obscure Practitioner" scarcely supports the claim for obscurity which he makes. His letter on the contrary indicates that he must be freely accustomed to ventilate his opinions upon the above subject. That being evidently the case he should therefore have had the courage of his convictions, and have appended his ordinary signature. Meanwhile I think that he is mistaken in the conclusions at which he has arrived. He points out that barely 2,000 members, out of a total of 20,000, took the trouble to record their votes upon the referendum; "it is amazing, it is deplorable, it is to me inexplicable," he says, "that this astonishing indifference should have been displayed." But the whole matter of the referendum had been thrashed out by the representative body, and agreed upon by the branches, and all that was wanted was to secure its official passing by the branches. This was easily accomplished as the voting has shown. To my mind the non-voters, by not taking part in the final act, merely showed their confidence in the promotion of the referendum. When it is common knowledge in the Association that Sir Victor Horsley was at the head of the reform movement ample reason exists for the apparent lethargy in voting, which has caused your correspondent so much surprise and regret. The smallness of the members voting does not indicate a want of interest in the matter concerned; it is only a proof that the great bulk of the Association was satisfied with the reforms which the referendum proposed to introduce. As a matter of fact this referendum will create a new era in the history of the Association—a new era which was badly needed. Among other things it will dispose of the family circle arrangement upon which the Council has for too many years been organised. Of course, the "old-timers" on the Council resent this effort to infuse new blood into the governing body of the Association. Many of them have doubtless come to regard the Council as a desirable club at which they can conveniently meet their friends, at the expense of the Association, for a chat. This may have been in Sir Victor Horsley's mind when he described the meetings of the *Journal* and *Finance* Committee as a "farce"—a statement so condemnatory as this could scarcely have been publicly made without ample proof to support it. The members of the Association, outside the majority of the Council, owe a debt of gratitude to Sir Victor Horsley and his coadjutors for having made so strenuous an effort to introduce reforms into the Association, on the lines of the referendum. Hitherto the members, not in office, have been regarded as mere cyphers, units without power or influence, puppets unworthy of notice—all this will now be changed—to the great benefit of the Association generally. I will follow your correspondent's lead, and sign myself,

Sir, yours truly,
Nil Desperandum.

SCIENCE, THE PEOPLE AND THE STATE.

To the Editor of The Medical Press and Circular.

Sir,—The study of your interesting paper by the non-medical scientific reader affords food for thought of many varieties; and to me nothing is more striking than the evidence you present almost weekly of the loss, and the danger to the State to which the present national neglect of science is giving rise. To minds below a certain standard science is, and must remain, a sealed book. Vast numbers of the common people—and by these I by no means imply the poor alone—have not the intellectual capacity to understand the meaning of a single scientific fact much less to follow, and appreciate a logical chain of reasoning composed of such facts. They are swayed entirely by transient emotions, or by the sufficiently long continued reiteration of any plausible statement. Placard the walls sufficiently with the statement that Dr. Bogus's pills will cure all diseases, or cry out with enough persistence that Free Trade, or Tariff Reform, or Socialism is the remedy for all disorders of the body politic, and the unreasoning crowd will adopt one or other of these panaceas, and swallow them in perfect faith. This is the frame of mind of the masses of the people, hence the dangers of democracy. Everything depends upon the leaders—upon their moral fibre and their mental training. If they are as ignorant of science as the crowd they sway, Heaven help the nation. At present probably more than one half of the men undergoing education for leading positions in the professional and political world are receiving no instruction whatever in science. There are, it is true, scientific "sides" at our public schools, but these are largely looked down upon by politicians and lawyers, and all save those destined for a scientific career. To many of these men when boys science was known under the designation of "stinks," and "stinks" it remains to them in after life, with a corresponding scorn of its professors. It is a fact to make one think when one sees in your pages an exposure of the attitude, say, of a distinguished lawyer towards medical science. Not infrequently you have shown us such a man who does not know, and scorns to learn what is meant by a disease; refuses to see that the true malady is not the superficial symptom by which it manifests itself, and cannot understand that suppression or mitigation of a nervous symptom by local narcosis or anæsthesia is no cure for concrete pathological tissue changes. This ignorance of physical science in general and of the bases of medical science in particular on the part of those who make, and those who administer, our laws lies at the bottom of the enormous development of the blatant quackery of the day—an atrocious evil, and by no means the least among the hurts inflicted upon the simple people through the incompetence of those to whom alone they can look for leadership and protection.

I am, Sir, yours truly,
A Science Teacher.

Birmingham, March 20th, 1908.

LAW FOR TRADERS AND LAW FOR QUACKS.

To the Editor of The Medical Press and Circular.

Sir,—In the *Times* of to-day is published the report of a case in which a London shopkeeper was summoned for selling a blouse as "Irish lace" which was, in fact, manufactured in France. The magistrate fined the defendant £20, with five guineas costs, and remarked that "if the defendant could not sell an article without telling falsehoods about it, he must drop its sale." Such is the law that regulates trade, and prevents false pretences of comparatively harmless kinds. On the other hand, there exists no law to interfere in any way with the traffic in quack medicines—a system of cruel and murderous fraud entirely founded on falsehood and deception. A tradesman may not sell French lace for Irish, but he may sell coloured lard as a cure for cancer, or coloured water as a cure for epilepsy, and in cunningly-worded advertisements may persuade ignorant and simple sufferers to put their trust in his worthless wares. That this state of things continues is entirely the fault of the profession. The case for medical law reform is overwhelming. It needs only to be stated authoritatively to compel the attention of statesmen and Parliament to make them recognise its urgency and devise without delay the legislation demanded.

I am, Sir, yours truly,
An Obscure Practitioner.

March 28th, 1908.

SANATORIA FOR PHTHISIS AMONG THE POORER CLASSES.

To the Editor of The Medical Press and Circular.

Sir,—In your issue of March 25th a report is given of the last meeting of the Edinburgh Medico-Chirurgical Society, and a large space is allowed to my paper on sanatoria. Whilst conscious that my paper was unworthy of such distinction as compared with the very able and original contributions of Mr. Alexis Thomson and Dr. Peel Ritchie, I was pleased that the subject which I was trying to bring before the profession thus received some prominence. You will excuse me if, in the interests of truth and my own credit, I ask permission to make a few corrections. I am reported to have said that the bacillus was "readily destroyed by air and sunlight," whereas it was only the latter which could be claimed as bactericidal. Again, I am reported to have stated that there were 10,000 beds available in Great Britain. I wish there were so many, for it would be an approach to the requirements of the case. At the time of my investigation there were only 1,084 as far as I could ascertain. Then I am reported to have said that in some sanatoria the cost per bed worked out at £300. The average cost of all the sanatoria open to the poor was about £350 per bed, and in some cases the capital expenditure reached the outrageous figure of £1,000 a bed. On the other hand some of the best institutions were built at or under £100 a bed, the test being (as it ought to be) the efficiency of the treatment. Lastly, the cost of the model sanatorium I showed the designs of was £100 a bed, and not £50, as stated by your reporter.

Permit me to say that there is no question more important than the financial one, if there is an appeal to be made on a national scale for the sanatorium treatment of early cases among the poorer classes. It is hopeless to expect either the charitable public, or the rating authorities, to build palatial structures where the poor would be ruined for the humble homes and faring of ordinary life. Efficiency is perfectly compatible with simplicity and economy.

I am, Sir, yours truly,
A. Walker.

Edinburgh, March 26th, 1908.

OBITUARY.

JOHN GABB, M.R.C.S., L.S.A.

We regret to record the death, which took place on March 26th, at Bewdley, of Dr. John Gabb, one of the oldest and best-known medical practitioners in Worcestershire, at the advanced age of 86. Dr. Gabb, who belonged to a Worcestershire family, was born in 1821 in the neighbourhood of Worcester. He had a distinguished medical course, being a gold medalist. He went to Bewdley in 1836, and was, subsequent to passing his final examination, in partnership for some years with his uncle, the late Dr. Cole. Since 1863 he practised alone, but for some years prior to his death he had retired from active work. He was a man of striking personality, and filled many public offices in Bewdley. He was by far the oldest magistrate, and till quite recently was a regular attendant at the police court. As a member of the Town Council for a prolonged period he rendered valuable services to the town; was several times elected an alderman; and filled the mayoral chair in 1863, and again in 1885-6 and 1886-7.

REVIEWS OF BOOKS.

TRANSACTIONS OF THE CLINICAL SOCIETY OF LONDON. (a)

It is with feelings of considerable regret that we start the review of this volume of the Clinical Society's Transactions, regret due to the fact that it is the last of the numbers to appear in its present guise. The Clinical Society, like most of the other London medical associations, has thought wise to merge its individuality in the Royal Medical Society, and henceforward it will consist of a section of that society, and its proceedings will be published along with the other records of the society. We trust that this change will in no way alter the character of the work that they have been doing, but will rather increase the usefulness and extend the limits of the association. We have long been accustomed to look upon their transactions as the most interesting of all the yearly publications which are especially devoted to internal medicine, containing, as they do, crisp accounts of the best clinical cases met with at the London hospitals during the year, and we would regard any great change in their character as a distinct loss to the medical profession. The volume now before us contains 34 papers, and 44 brief accounts of cases shown at the various meetings. Almost all of the records are of special interest, and well merit careful perusal, so that it is with difficulty that we can single out any of the papers for special notice. The Presidential Address by Dr. Clutton is devoted to an account of three cases of late rickets, followed by a brief discussion concerning the causes of and the treatment of the condition. The paper is illustrated by X-ray photographs, and is succeeded by a short paper on the same subject by Dr. Muirhead Little. Forsyth contributes an account of a fatal case of myxœdema, in which the parathyroid glands were found to contain an abundance of colloid material, due, the author believes, to a compensatory functional activity on their part. This paper adds further weight to the gradual store of evidence which is accumulating in favour of the parathyroids being merely accessory thyroids, instead of independent glands, with an independent function. Another interesting paper, from the pathological point of view, is the sequel to one on a case of "Juvenile General Paralysis of the Insane," reported by Dr. Lunn a year previously. The post-mortem examination by Dr. Gordon Holmes showed the existence of a chronic inflammatory process, and other changes which amply confirmed the diagnosis. Havilland Hall writes an interesting article on "Prolonged Pyrexia," and Langmead records four cases in children of tetany associated with dilatation of the large intestine. Numerous papers of surgical interest are included, amongst which the most striking is, perhaps, that of Moynihan on "Mimicry of Malignant Disease in the Large Intestine." On the whole, the present volume is as interesting and useful as its predecessors, and we advise all interested in clinical work to obtain it.

LABORATORY NOTES.

THE EUSTACE MILES FOODS.

We have received specimens of foods prepared by the Eustace Miles Restaurant Company, Limited, and have submitted the same to a careful examination. These foods purport to be both rich in nourishing constituents and easily digestible, and our experiments show that these claims are amply justified. We find the "Emprote" Proteid Food to contain a large amount of proteid matter (30 per cent.), and generally to be a most satisfactory preparation. The Eustace Miles Nourishing Cocoa likewise contains a much larger amount of protein matter than is to be found in ordinary cocoas—the actual percentage of protein as found by us being 27.9 per cent. This cocoa contains a satisfactorily small amount of moisture (4.7 per cent.) and 6.8 per cent. of mineral matter. The amount of matter soluble in water is very high, viz., 47.3 per cent., which is about 30 per cent. more than is normally found in cocoas. We feel sure that these foods will be very much appreciated by patients and also by those whose digestive faculties are below the normal.

Many of the Infants' Foods on the market are absolutely unsuitable for use owing to a deficiency of fat. The Eustace Miles Nourishing Food for Infants is very satisfactory in respect of this constituent, which it contains to the extent of 21 per cent.

GRAY'S GLYCERINE TONIC COMP.

Our analysis shows that this preparation contains 11.42 per cent. of alcohol (by volume) and about 45 per cent. of extractives. It is a judicious combination of glycerine, gentian, taraxacum, phosphoric acid, sherry and carminatives, which form a palatable and readily taken tonic. So far as we have tried it, it has no constipating action on the patient, while it stimulates the appetite and removes depression. It is said to have proved valuable in the treatment of pulmonary consumption, diabetes, marasmus, and other diseases associated with defective nutrition, but of this we have no knowledge. It has been found to give good results in nervous exhaustion, neurasthenia, general debility and bronchitis.

The tonic is made by the Purdue Frederick Company, of New York, and is to be obtained from Messrs. E. J. Reid and Co., of Dunedin House, London.

The Asylums Committee of the London County Council are recommending the Council to accept the offer made by Dr. Henry Maudsley to contribute £30,000 towards the cost of the erection and equipment in London of a hospital of 100 beds for the treatment of cases of recent and acute mental disorder.

(a) "Clinical Society's Transactions." Vol. XL. London: Longmans, Green and Co.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT SURGICAL LITERATURE.

Some Observations on the Use of Tobacco in Surgical Practice.—Bangs (*Med. Record,* March 14th, 1908) believes, and reports some surgical cases in support of the fact that the withdrawal of tobacco is sometimes followed by irritability and restlessness, and not infrequently by a vital depression not to be accounted for by the surgical state. In one case internal urethrotomy was performed on an otherwise healthy young man, æt. 26, who was an inveterate cigarette smoker. Everything went on well for six days. He was then persuaded by his mother to give up smoking. He spent a restless night. About 2 p.m. next day he became collapsed. His face was ashy and covered with clammy sweat. His respirations were shallow and laboured. His pulse was feeble and fluctuating. He had the appearance of someone suffering from extreme shock. There was no apparent reason for the condition. There was no hæmorrhage from the urethra, chill, nor rise of temperature. He had eaten a good breakfast. The author noticed the absence of the stumps of innumerable cigarettes which he had been accustomed to smoke all through his illness, and found he had not smoked since the previous morning. Brandy and water had little effect. A cigarette was placed in the patient's mouth and lit for him. He took a few feeble whiffs, inhaling each time, and then, as his respiration became stronger, he inhaled the smoke vigorously. In a few seconds his usual colour came back to his face, the sweating stopped, and his heart-beats became stronger and regular. This is all that was done for him, and his return to his normal condition was rapid. The author gives an account of two other similar experiences in highly neurotic patients who had suddenly stopped smoking after operations for hæmorrhoids and appendicitis. S

The Unbalanced Foot.—McKenzie (*Canada Journal of Med. and Surg.,* March, 1908) says that a lack of balance, so that the foot is not maintained directly under the body weight, is an important, if not the chief cause of discomfort and disability in walking. In the slighter cases balance may be restored by the use of properly constructed boots and braces. In young persons especially, education and development of the muscles is an important factor in treatment. Tendon transplantation to restore balance is indicated in infantile paralysis, as little can be done by art in the way of improving the condition of the muscles disabled This treatment is fairly satisfactory in its results. Excision of the ankle-joint in "flail foot" has proved itself a highly satisfactory method of treatment. Osteotomy is frequently necessary, especially after injuries of the leg near the ankle. The author also points out that a properly designed night brace is important to prevent deformity. In all cases the great essential is to place and maintain the foot evenly and directly under the body weight. S.

Modern Treatment of Surgical Tuberculosis.—Low (*Brit. Med. Journ.,* March 7th, 1908) summarises the treatment of surgical tuberculosis thus:—(1) In all cases open-air treatment should be organised to meet the circumstances and requirements of the case. (2) The patients' powers of resistance to the disease should be periodically measured by suitable blood examination. (3) When the resistance is found to be low, and there is no evidence of excessive auto-inoculation, use should be made of inoculation of Koch's new tuberculin, in doses that are accurately controlled, both as regards their amount and repetitions, by examination of the blood. (4) In patients in whom there is evidence of excessive auto-inoculation, absolute rest, with, in the case of a limb, absolute fixity of the diseased part, should be prescribed. (5) In cases of circumscribed tuberculosis, efforts should be directed to increase the circulation through the diseased area. (6) Operative procedures should be directed to the removal of the inert materials, whether caseous glands, carious bone, or collections of pus, and allowing the access to the infected area of healthy lymph. The necessary operations should be conducted with the most scrupulous asepsis. S.

Production of Pseudo-Arthrosis of the Hip without Disarticulation of the Head.—Jones (*Brit. Med. Journ.,* February 29th, 1908) points out that it is inexpedient to disarticulate the head of the femur in osteoarthritis with deformity, and also in ankylosis, on account of shock. After osteotomy to correct flexion, it is difficult to avoid union. Having tried osteotomy with interposing gold-foil and soft structure between the fragments to prevent re-union, the author finds that the following operation gives the best results. This consists in removing a slice of the great trochanter, chiselling through the neck, and sewing the separated portion of the great trochanter to the proximal end of the neck to ensure non-union of the fragments. The neck may be chiselled close to the head, or at a little distance from it, or the neck may be completely removed. The operation is not admissible in the case of children. It is performed as follows:—A longitudinal incision is made about 6 in. in length from the upper part of the trochanter to its centre. An incision is made across the base of the trochanter just below the insertion of the gluteal muscles. A slice of the trochanter from this point to its junction with the neck above is sawn or separated by a very wide osteotome and retracted upwards. The capsule is now opened, and the head separated from the neck with an osteotome. Extension is next put on the femur, and the trochanter, with its muscles attached, is screwed on to the head of the femur, which remains in the acetabulum. Deep and superficial sutures complete the operation. This operation is very suitable to those advancing in years. In bony ankylosis the femur is well supplied with muscles for useful movement, and no stitching of the capsule is necessary for the prevention of displacement upwards. S.

Report of a Case of Intussusception.—Hooper (*Canada Lancet,* February, 1908) reports the following case:—A child, 8 months old, had passed only a little blood and mucus per rectum for three days. The patient seemed to experience little pain, but was somewhat fretful. Its general appearance was fairly good. The abdomen was not tense, and palpation did not reveal any unusual condition. On examination per rectum a tube-like structure was felt in the sigmoid region. The abdomen was opened in the middle line. A crescentic-shaped tumour was found, with its lower extremity near the sigmoid flexure. The intussusception was of enteric type, and involved the jejunum in its upper part. The sheath slipped easily from its intussuscepted portion. The surfaces, though deeply congested, were free from adhesions. On reduction the distal portion of the bowel became immediately inflated with air. In spite of the easy reduction of the intussusception, the short time of the operation, and the good quality of the pulse after it, vomiting, which had commenced before the operation, continued, and became more frequent. General paresis of the bowel resulted in this case, and every effort failed to restore peristaltic activity. The child died in a few hours. S.

Finsen Light Treatment.—J. H. Sequeira (*Lancet,* March 7th) gives his experience of Finsen light work at the London Hospital for seven years. 791 cases of lupus vulgaris were treated. Of these, 71.6 per cent., or 429 cases, were cured. Some have been now

for nearly six years without treatment, and the disease shows no sign of recurrence. In cases where the lupus was very extensive and advanced, cures were not always obtainable. 107 cases were improved by this treatment; that is to say, while the disease is not cured, it has been stopped from spreading, if not considerably diminished in amount. In 23 cases the treatment failed entirely to do any good. In the remainder of the cases the treatment was abandoned for some other cause than failure. Lupus erythematosus did not yield so readily to this form of treatment. Of 68 patients treated, only 26 derived definite benefit from the action of the Finsen light; 14 cases of rodent ulcer were treated; some were improved, but the results were not very definite, and the author now treats all such cases by means of the X-rays, as this gives more certain results. Five cases of cutaneous nævi were treated; all showed improvement, but the treatment is so slow and tedious that it cannot be recommended except in the case of small nævi. A few cases of pigmented moles were treated, but all without success. One case of leucoderma was treated, but without any benefit. Several cases of alopecia areata were treated, but the benefit derived from the light reaction appeared to be no greater than that following treatment by the usual stimulants, cantharides, etc. Several cases of keloid were treated with considerable benefit. The results were not more striking than those seen after X-ray work, which has the advantages that there is no inflammatory reaction, and a much greater area of disease can be treated at the one time. Some X-ray scars were much improved by the Finsen light; the results seem to be better than those obtained by any other method of treatment.
G.

Carbolic Acid Gangrene.—J. Murphy (*Intercolonial Journ.*, January, 1908) records the case of a healthy man, æt. 25, who had crushed his fingers while at work seven days before. The fingers were very sensitive. A solution of carbolic acid, strength not known, was applied on lint, and the finger bandaged up. Soon after the fingers became somewhat numb. About 17 hours later the dressing was removed. The fingers then looked well, but were pale, and without sensation. Six days later, when the patient came under Mr. Murphy's care, the fingers were normal in size, cold, yellowish white and anæsthetic; they could move freely. Ten days later the colour became brown, and a definite line of demarcation began to appear, and a week later both gangrenous fingers were amputated. The digital arteries were normal in size, and spurted vigorously when cut across, showing that the blood supply of the fingers originally was very good. Gangrene of the extremities following the application of carbolic acid is not a very uncommon occurrence. Many cases are recorded of gangrene following the continued use of a 1 per cent. solution for 24 hours, a 2 per cent. solution of the acid in 12 hours, and stronger solutions in from three to four hours. The danger is not recognised by the patient, as the carbolic renders the part anæsthetic. Carbolic acid, even in weak solutions, must be looked on as a distinctly dangerous continuous local application to the extremities, more especially where their vitality has been previously lowered by injury or disease. G.

A Symptom of Movable Kidney.—J. Brena (*Lancet*, January 4th, 1908) calls attention to the following symptom, which he has found useful in the diagnosis of movable kidney. Persons habitually constipated, or who have to make great exertion on defæcation, when emptying or beginning to empty the bladder feel a sudden sharp pain, which stops the flow of urine and runs through the urinary passage with all the characteristics of a urinary colic. Instinctively the patient changes his position, rises from his seat, and puts his hand on the lower abdomen, pressing or rubbing the side affected, and the pain disappears as suddenly as it came on, micturition goes on, and everything proceeds in due course. The phenomenon appears to be due either to compression of the kidney, caused by the effort to evacuate the fæces, or to sudden obstruction of the ureter by excessive twisting or distension. G.

Migraine and Errors of Refraction.—A. R. Baker publishes, in the *Ophthalmic Record*, January, 1907, the results of having sent a circular letter to 100 patients who had suffered from migraine, and for whom he had ordered glasses. He asked three questions:—"How frequently did you have attacks of sick headache before you were fitted with glasses?" "How frequently have you had such attacks since you were fitted with glasses?" "Do you have a return of the headaches if you leave off the glasses?" The refraction of these patients had been estimated under a cycloplegic. In most cases the total error of refraction had been corrected. The answers received to the above questions went to show that 55 patients were cured and 31 much improved. The glasses had no effect on the remaining 14, but 5 were cured by tenotomy, 1 by wearing a pessary, and 8 were unrelieved. In answer to the third question, 89 patients said "Yes"; 85 of the hundred patients had astigmatism in one or both eyes. Of the 200 eyes examined, 134 were hypermetropic, 21 myopic, and 25 mixed. Astigmatism occurred in 85 of the 100 patients, and an oblique axis in 42. Baker was prompted to ascertain these facts on account of Posey and Spiller, in their "The Eye and Nervous System," having denied that the refraction of the eye played an important part in causing migraine. On the contrary, Baker maintains that the most frequent cause of migraine is eye-strain, due, as a rule, to astigmatism; that migraine need not necessarily disappear at 40 or 50 years of age, when accommodation commences to be limited; and that some cases of eye-strain which cause migraine may be of emmetropic refraction.
M.

MEDICAL NEWS IN BRIEF

The Royal College of Surgeons of Ireland and the Proposed New University.

The President and Council of the Royal College of Surgeons of Ireland have addressed a letter to the Chief Secretary for Ireland in which they point out the disastrous results which the establishment of a new and endowed medical school will have on the Medical School which is at present so successfully conducted by the College. The letter points out that if such a school is established "there will be in Ireland six schools, five of whch will be substantially endowed with public money, and one, our College School, will be without endowment. It is obvious that such hopelessly unfair competition must inevitably cause our School to close its doors, and the destruction of the School will at an early date entail the destruction of the College."

The letter then continues:—

"We seek no monopoly of medical education. We do not desire to hinder or delay educational proposals wished for by any body of our countrymen. We ask only that when such proposals are being carried into effect provision will be made to prevent the destruction of an ancient and distinguished College, the closing of a large and increasing school, and incidentally the beggaring of such of its professors as rely solely upon the income of their chairs for their livelihood.

"The most simple and effective safeguard would be an annual grant of an amount sufficient to permit us to maintain our College and its school in a state of efficiency. This sum we estimate at £5,000 per annum. But we have reason to believe that a direct grant may be withheld.

"We have, therefore, after anxious consideration, come to the conclusion that as an alternative solution, we would be willing that the precedent of London University should be adopted, and that our school should be made a 'constituent school' of the new University. Provision would then be made in the Bill that our school be placed *cæteris paribus* in the same position as the proposed School of Medicine with regard to equipment, endowment, scholarships, privileges, representation on Senate Examining Board, and the like.

"Our school would continue to educate candidates for our diplomas, as well as for degrees of the new University. It would remain under our management, but in so far as it was concerned with the education of University students, it would be subject to the supervision of the medical faculty and Senate of the new University."

We refer to this important subject again in our editorial columns.

Liverpool and Tuberculosis.

THE annual meeting of subscribers, donors, and friends of the Liverpool Hospital for Consumption and Diseases of the Chest, Mount Pleasant, and the Liverpool Sanatorium, Kingswood, Delamere Forest, was held on March 24th, in the Liverpool Town Hall, the Lord Mayor presiding.

Mr. Alfred Shawfield submitted the 44th annual report of the committee. A large measure of success has resulted from the sanatorium treatment where it has been undertaken for those in the primary stage of the disease. Preference in admission is given to applicants in that stage, and it is gratifying to have a late statement from the resident medical officer at Delamere that they have recently had an increased percentage of these primary cases. An important extension there during the past year has been the erection and equipment within the hospital grounds of a laboratory designed to undertake the most modern research. In their report for 1906 the hon. medical staff at Mount Pleasant referred to the measure of pathological work which they were already undertaking in an improvised laboratory which was then existing, and particularly in connection with what is known as the "Opsonic treatment for consumption." The laboratory is under the hon. superintendence of Dr. Henry Clarke, having under him a qualified assistant, Dr. C. E. P. Forsyth, who likewise fills the post of stipendiary to the hospital. In the main the committee are once more indebted to the liberality of their president, Mr. W. P. Hartley, for the pecuniary means of maintaining a qualified assistant in the laboratory, he having increased his annual subscription by £100 towards that specific end. The whole cost of the laboratory and equipment will be met out of special donations for that purpose, amounting to about £1,260, contributed by a few friends of the charity, so that no part of the cost will fall on its own capital funds. The year ended with a debit balance in maintenance account of £679 5s. 3d., and a credit balance in capital account of £68 6s. 11d.

Earlier in the day the Lord Mayor, accompanied by the Lady Mayoress, visited the Consumption Hospital in Mount Pleasant and opened the new laboratory which has been provided for research work and other very valuable purposes. The new premises are at the rear of the hospital.

Infant Life Protection.

THE report of the Select Committee appointed to inquire "and report as to the desirability of extending the provisions of the Infant Life Protection Act, 1897, to homes in which not more than one infant is kept in consideration of periodical payment," expresses the opinion that the body of facts laid before the committee by those who urge the extension of the Act was not displaced by any contrary evidence. Having regard to the serious amount of evil thus brought under their notice, the committee recommend that the provisions of the Infant Life Protection Act, 1897, should be extended to homes in which not more than one infant is kept in consideration of periodical payment. They are, however, of opinion that some of the objections urged by the witnesses against extension deserve serious consideration. The committee believes there are a large number of these one-child cases where the infant is received from motives of a real affection for children in general, or for some child or parent in particular. On a careful review of this aspect of the case the committee are of opinion that some power should be given to the local authority to exempt, on such terms and conditions as it may think fit, any particular home in their district from inspection, or to make arrangements for any such inspection to be made by a properly-constituted benevolent society, if the local authority are satisfied that the interests of the child will be safeguarded.

Prosecution of an Alleged Bogus Doctor.

At Dungannon last week a charge was preferred against a man named James Maguire, under the Medical Acts, 1858 and 1886, of having unlawfully pretended to be, and used the title of, Doctor of Medicine, thereby implying that he was a registered medical practitioner under those Acts. Mr. Meglaughlin, solicitor, prosecuted on behalf of the Medical Defence Union, and Mr. W. J. Reynolds, solicitor, represented the defendant. On the case being called, Mr. Reynolds raised the preliminary objection that the prosecution had been brought in the name of a solicitor's clerk, who had made a deposition in the matter, instead of by the General Medical Council. Mr. Meglaughlin contended that any person who had the necessary knowledge of the facts could bring the prosecution, and he quoted decisions in the English Court of Appeal in support of his argument. The magistrates, however, by nine votes to seven, decided in favour of Mr. Reynolds, and dismissed the charge without prejudice.

Medical Graduates' College and Polyclinic.

THE annual general meeting of the Medical Graduates' College and Polyclinic was held on Friday evening at 22, Chenies Street, Bloomsbury, Dr. C. Theodore Williams presiding. The ninth annual report, the adoption of which with the balance-sheet was moved by the chairman, stated that a large amount of work had been done during the year, and there was gratifying evidence of the fact that the polyclinic filled a very real want in the later education of the medical practitioner. As many as 1,127 cases of disease, many of them of extreme rarity and interest, had been shown, and the attendance of medical practitioners at the cliniques and lectures made a grand total of 13,862 for the year.

University College Hospital Needs.

AT the annual general meeting of University College Hospital, on March 27th, it was announced that an available ward, containing 24 beds, could not be opened for lack of means. This means that about 350 of the sick poor each year, many requiring immediate treatment, have to be refused admission. An additional annual expenditure of about £1,200 would be required to keep the ward open, and the committee have not felt justified, owing to the financial state of the charity, in incurring this further liability. The upkeep of the hospital involves £28,000, there being the charge of nearly 3,300 poor sick people in the wards and treatment of over 50,000 out-patients to be provided for. The committee again appeal to the benevolent for the endowment of cots and beds.

Trinity College, Dublin.

THE following candidates passed the Final Medical Examination (Surgery), Part II., during Hilary term, 1908:—William S. Thacker and John L. Phibbs (passed on high marks), Thomas P. Dowley, Alfred H. Smith.

The following passed the Intermediate Medical Examination, Part I.:—Herbert de L. Crawford, Douglas M. Moffat, Hugh R. M. Ferguson (Sch.), Arnold K. Henry, George F. C. Healy, Thomas A. Watson, John B. Burgess, Ernest W. G. Young, Thomas M. Crawford, Richard P. Pollard, Charles H. Denham, James Beckett, Cecil Grene.

The following passed the Final Examination in Medicine, Part II.:—Midwifery: James P. S. Dunn, Charles W. Laird, passed on high marks; David J. Miller, David G. Madill, Arthur H. Laird, Alexander K. Cosgrave, James F. Clarke, Norman P. Jewell, Edward J. H. Garstin, Richard J. Attridge, Frederick R. Sayers, John C. Baker, William H. L. M'Carthy, Alexander S. M. Winder.

Catholic University School of Medicine.

AT a meeting of the Board of Governors of the above institution, held on Friday, the 27th ult., the Chair of Medical Jurisprudence and Hygiene, vacated by the death of the late Professor Antony Roche, was filled by the appointment of Professor E. J. M'Weeney, M.D., D.P.H., F.R.C.P.I.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Dr. R. S. (Birmingham).—A copy of this journal of the date referred to has been sent to Paris, as desired.

Mr. T. C. J. (Liverpool).—From your description of the case, we fear the result was unavoidable, but no useful purpose would be served by publication

Dr. B. H. S.—The law regarding medical practitioners in Queensland is pretty much the same as in other parts of Australia and in Great Britain. Registration is conducted by a duly appointed Medical Board. Dentists, however, are not affected by the Act in force. Fraudulent registration is punishable by imprisonment, and any person falsely pretending to be a medical practitioner is subject to a heavy penalty.

Meetings of the Societies, Lectures, &c.

Tuesday, March 31st.

Royal College of Physicians (Pall Mall East).—5 p.m.: Sir James Sawyer: Points of Practice in Maladies of the Heart. (Lumleian Lecture.)

Wednesday, April 1st.

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. C. Ryall: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. C. O. Hawthorne: The Clinical Anatomy and Physiology of the Nervous System.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipman); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

Thursday, April 2nd.

North-East London Clinical Society (Prince of Wales's General Hospital, Tottenham, N.).—4.15 p.m.: Discussion: (1) Does Chloroform Administration tend to the Production of Post-partum Hæmorrhage (opened by Dr. Bowie); (2) Anæsthetics in General Practice (opened by Mr. H. Wallace).

Royal College of Physicians (Pall Mall East).—5 p.m.: Sir James Sawyer: Points of Practice in Maladies of the Heart. (Lumleian Lecture.)

Medical Graduates' College and Polyclinic (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. G. Barling (Birmingham): The Diagnosis and Treatment of Renal Mobility.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). 4.30 p.m.: Throat Operations (Mr. H. W. Carson).

Friday, April 3rd.

Royal Society of Medicine (Laryngological Section) (20, Hanover Square, W.).—5 p.m.: Cases and Specimens:—Dr. Jas. Donelan: (1) Case of marked Nasal Obstruction resulting from Neglected Adenoids; (2) Case of Nasal Obstruction with Deflected Septum. Dr. StClair Thomson: Two Radiographs illustrating Value of X-Rays in Sounding and Washing-out the Frontal Sinus. Dr. Scanes Spicer: Case of Intrinsic Neoplasm of Left Vocal Cord. Dr. Dundas Grant: (1) Case of Thyro-lingual Fistula treated by Electrolysis and Excision; (2) Case of Chronic Frontal Sinusitis treated by Irrigation.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8 p.m.: Clinical Meeting.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. W. Dodd: Clinique. (Eye.)

Appointments.

Cope, V. Zachary, M.D., B.S.Lond., Surgical Registrar to the London Temperance Hospital.

Edwards, Albert Davies, M.B., B.S.Lond., D.P.H.Edin., Assistant Medical Officer and Assistant Schools Medical Officer by the Newport (Mon.) Education Committee.

Giles, James A., M.B., B.S.Durh., Assistant Medical Officer of Health of the County Borough of Devonport.

Howard, Russell, M.S.Lond., F.R.C.S.Eng., Curator of the Museum of the London Hospital Medical College.

Lanyon, George Edward, M.B., C.M.Edin., Medical Officer of Health for the Falmouth and Truro Port Sanitary Authority.

Mill, G. Robertson, M.D.Edin., Honorary Anæsthetist to the Liverpool Dental Hospital.

Richmond, D. S., M.B., Ch.B.Glasg., Medical Officer and Vaccinator to the Parish of Dalry, Kirkcudbrightshire.

Vacancies.

Ayr District Asylum.—Junior Assistant Medical Officer. Salary, £120 per annum, with lodging and laundry. Applications to Dr. McRae, Glengall, Ayr.

Canterbury Borough Asylum, Canterbury.—Assistant Medical Officer. Salary, £140 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Edinburgh District Asylum, Bangour Village.—Second Assistant Physician. Salary, £120 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Bangour Village, Uphall.

Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, 18, Emmanuel Street, Cambridge.

York Dispensary.—Resident Medical Officer. Salary, £120 a year, with board, lodging, and attendance. Applications to W. Draper, Esq., De Grey House, York.

County Borough of Warrington.—Assistant Medical Officer of Health. Salary, £125 per annum, with board and residence. Applications to J. Lyon Whittle, Town Clerk.

London Fever Hospital, Liverpool Road, N.—Assistant Resident Medical Officer. Salary, £150 per annum, with residence and board. Applications to the Secretary, at the Hospital.

Borough of Cambridge.—Medical Officer of Health. Salary, £500 per annum. Applications to J. E. L. Whitehead, Town Clerk, Guildhall, Cambridge.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

Births.

Brown.—On March 26th, at 1, Bartholomew Road, London, the wife of Alexander Brown, M.B.Lond., M.R.C.S., of a daughter.

Marriages.

Dickson—McLaggan.—On March 25th, at St. John's Church, Buxton, Francis Henry Dickson, M.B., Ch.B.(Edin.), of Oxford, youngest son of the late Francis Kennedy Dickson, F.R.C.P. and F.R.C.S., J.P., to Margaret Sophia McLaggan, eldest daughter of the late Alexander McLaggan, of Bombay.

Taylor—Henderson.—On March 27th, at the Church of St. Edward, Lugano, William Macrae Taylor, M.B., C.M., F.R.C.S.E., of Edinburgh, eldest son of William Taylor, M.D., F.R.C.P.E., to Hermina Janet, only daughter of Robert Charles Henderson, Gentilino, Lugano, formerly of Leghorn, Italy.

Worthington—Peacock.—On March 24th, at St. James's Church, Muswell Hill, Oscar Clayton, M.R.C.S., L.R.C.P., second son of the late George Finch Jennings Worthington, M.R.C.S., M.R.C.P.I., to Lousia Jane, daughter of the late Joseph Charles Peacock.

Deaths.

Attfield.—On March 23rd, at San Remo, Italy, in his 42nd year, after suffering for five years from consumption and recently influenza, Donald Harvey Attfield, M.A., M.B., formerly Medical Officer of Health at Watford, and afterwards for several years Chief Maritime Medical Officer of Health for the Egyptian Government at Suez, son of Professor Attfield, F.R.S., of Watford. Friends please accept this the only intimation.

Chamberlain.—On March 22nd, at his residence, Twynham, Park Road, Bournemouth, Charles Basham d'Eyncourt Chamberlain, Surgeon, R.N., retired.

Emerson.—On March 22nd, at 21, Goldington Road, Bedford, David North Bomford Emerson, Esq., B.A., M.B., T.C.D., youngest son of the late John Emerson, of Deer Park, King's County, aged 43.

Gabb.—On March 26th, at Bewdley, John Gabb, J.P., M.R.C.S. Lond., L.R.C.P., etc., in his 87th year.

Lorimer.—On March 25th, at Nelson House, Nelson Street, Oxford Road, Manchester, George Lorimer, M.A., M.D.(Edin.), of Buxton, only son of the late Rev. Archibald Lorimer, of Cockenzie, N.B.

Worthington.—On March 25th, at 95, Beaconsfield Villas, Brighton, Thomas B. Worthington, M.D., late Medical Superintendent of the Hants County Asylum, eldest son of the late Thomas Worthington, Esq., Dublin.

MODERN THERAPY

Bacterial Vaccines

prepared in the Vaccine Laboratory of the Department for Therapeutical Inoculation, St. Mary's Hospital, London, W., under the supervision of the Director, Sir A. E. Wright, M.D., F.R.S., etc.

STAPHYLOCOCCUS VACCINE

Prepared from cultures of various strains of staphylococcus.

Applicable to the treatment of ordinary furunculosis, suppurating acne, staphylococcic sycosis and all other forms of staphylococcus infection.

Supplied in three dilutions, respectively containing 100, 200 and 500 millions of staphylococcus *per c.c.*

GONOCOCCUS VACCINE

Prepared from cultures of gonococcus.

Applicable to the treatment of chronic gonococcal rheumatism.

Supplied in a dilution containing 5 millions of gonococci *per c.c.*

STREPTOCOCCUS VACCINE

Prepared from cultures of streptococcus isolated from cases of erysipelas.

Applicable to the treatment of streptococcal lymphangitis, erysipelas, and other strictly localised forms of streptococcus infection.

Supplied in two dilutions, respectively containing 5 and 10 millions of streptococci *per c.c.*

TYPHOID VACCINE

Prepared from cultures of the typhoid bacillus.

Applicable only for preventive inoculation.

Supplied in two dilutions, respectively containing 1000 and 2000 millions of bacilli *per c.c.*

TUBERCLE VACCINE ("Tuberculin")

This vaccine consists of Tubercle Bacillary Emulsion. It is applicable in particular to the treatment of chronic, strictly localised, and apyrexic tubercular affections. It is supplied in two dilutions, respectively containing *in each c.c.* 1-2000 and 1-5000 milligramme of the comminuted tubercle culture.

These vaccines are intended to be used solely under the direction of a medical practitioner. They are supplied in hermetically-sealed glass bulbs containing rather more than 1 c.c. Further information will be sent on request.

Sole agents for the sale of the above-mentioned Bacterial Vaccines:

PARKE, DAVIS & Co., 50-54 BEAK ST., REGENT ST., LONDON, W.

Telegraphic and Cable Address: "Cascara, London." Telephones: 8636 Gerrard; 9201 Central.

The published statements of prominent surgeons of all countries show that

ARGYROL

(Silver Vitellin)

is the best silver salt, and that no known agent can compare with it in eradicating gonococcal and other infections, speedily and without discomfort to the patient.

Argyrol is used in 10 per cent. solution as injection in gonorrhœa every 3 hours; in 25 per cent. solution as instillation (diseases of eye) every half hour or hour, and in 25 per cent. solution as local application (throat, vagina, etc.) once daily.

Produced by

BARNES & HILLE,
32 Snow Hill, LONDON, E.C.

One unique effect of

OVOFERRIN

(Iron Vitellin)

is its property of improving the patient's general nutrition in a very striking manner.

Literature on Ovoferrin by recognized authorities in medicine in America and Europe, show that it is a hæmatinic and general tonic of very unusual value.

Ovoferrin is furnished by chemists, on prescription, in twelve-ounce bottles. The dosage is one tablespoonful in wine-glass of water or milk three times daily.

Produced by

BARNES & HILLE,
32 Snow Hill, LONDON, E.C.

TRADE 'ALAXA' MARK

AN AROMATIC LIQUEUR
OF CASCARA SAGRADA

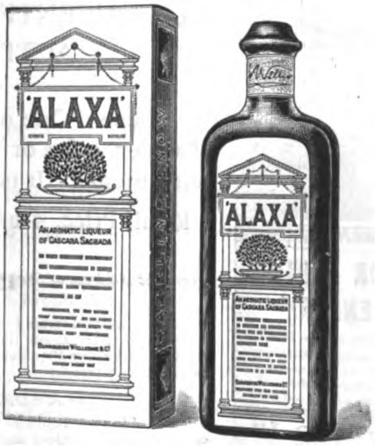
'ALAXA' presents a *fluid* cascara of the same high therapeutic standard as 'TABLOID' CASCARA.

'ALAXA' is the result of specialised study and research, and embodies the nearest approach to the isolation of the pure active principle of Cascara Sagrada yet obtained.

Its laxative action is supplemented by stomachic and carminative constituents.

'ALAXA' is so palatable that it may be given as an aperient *apéritif* or a laxative *liqueur.*

Careful clinical tests have confirmed its certainty of action and its superiority to bitterless extracts treated with excess of alkali, and rendered comparatively inactive in consequence.



One fluid drachm contains the equivalent of twenty-four minims of Liquid Extract of Cascara Sagrada, B.P.

SPECIAL NOTE

Cordials and Elixirs are so loaded with syrup and flavouring matter that a large dose is required.

The full dose of 'ALAXA' is 2 fluid drachms.

Supplied to the medical profession, in 4-oz. bottles, at 2/- per bottle

Liquor Pepticus

(BENGER)

A CONCENTRATED AND EXCEEDINGLY ACTIVE FLUID PEPSINE.

Dose: One or two tea-spoonfuls in a wine-glass of water, wine or weak spirit and water, as a digestive, with meals. It is without disagreeable taste.

Retail Price, 4-oz. bottles 3/-; 8-oz. 5/6; 16-oz. 10/6.

From the Address of Sir WILLIAM ROBERTS, M.D., F.R.S., &c., at the Northwich Meeting of the British Medical Association.

"Those of you who from past experience have lost faith in Pepsine may be encouraged to try again the more active preparations which are now within our reach. A Liquor Pepticus, prepared by Mr. BENGER, is a digestive agent of extraordinary power."

The MEDICAL TIMES AND GAZETTE says:—

"The 'Liquor Pepticus (Benger)' is singularly free from all disagreeable smell or taste; is clear and bright; and is a remarkably active Fluid Pepsine. It is worthy of all praise as a skilled preparation, and its high value as a digestive agent has been well proved by large experience."

BENGER'S
CONCENTRATED
ENCE OF RE
FOR PRODUCING
Curds and Whey,
DIRECTIONS FOR USE
PREPARED BY
GER'S FOOD L
MANUFACTURING CHEMI
TER WORKS, MANCH

Benger's Essence of Rennet.

(CURDLING FLUID.)

Bottles 1/- and 1/9 each.

This is most strongly recommended for making delicious and wholesome Junket or Curds and Whey. The process is very simple. A pint of milk is warmed and a tea-spoonful of the Essence added. In five minutes the dish is ready for use. A shilling bottle is sufficient to make 32 pints.

Dr. HENRY ASHBY, Physician to the Manchester General Hospital for Children, says in the "British Medical Journal":—

"Mr. BENGER has recently prepared an exceedingly active and reliable curdling fluid, which I have put to some crucial tests, and I believe it will be found very useful in preparing whey, and will supersede the use of Rennet, or any of the essences."

To be obtained from all the leading Chemists, etc., or of

BENGER'S FOOD Ltd., Otter Works, Manchester.

THE MEDICAL PRESS AND CIRCULAR.

VOL. CXXXVI. WEDNESDAY, APRIL 8, 1908. No. 15.

NOTES AND COMMENTS.

The Casualties of Science. THE humane treatment of the wounded in industrial warfare has developed very rapidly in the last fifteen years, and the sweeping measure of compensation passed the year before last marks in a very practical way the growing sense of responsibility felt by the community towards those wounded in its peaceful service. Indeed, looking at the provisions of that Act, it is hardly possible to resist the conclusion that compensation for disability incurred by labour can stop short where it is at present left, and that the future will see the benefits it awards extended till sickness of every kind is included. However that may be, the person chiefly handicapped by having to provide for others is the small employer, who is struggling to make an honest living for himself and to lay aside something against his own misfortune and old age. The medical practitioner, who has no regular employer but is the servant of many, has no one to whom to look for help when laid aside by the casualties of his calling, and provision, if provision there is to be, has to be made out of his own scanty earnings. It certainly is encouraging, however, to see that the claims of scientific workers disabled by the accidents of their occupation, are receiving some public recognition. In the case of Dr. Hall-Edwards, who is suffering so grievously as the result of his ardour, not only has a sum of £1,000 been publicly subscribed, but a Civil List pension of £120 a year been granted to him by the Government. These sums are miserably small, doubtless, and they will, we hope, be substantially increased, but the very fact that public sympathy is aroused and is taking practical shape is a matter for great thankfulness.

American Recognition. A SIMILAR, and equally cogent, case for like consideration is put forward by the London Hospital authorities in the person of their own X-ray operator, Mr. Ernest Harnack, who, though not actually a medical man, has by his skill and knowledge brought his department to a very high state of efficiency. Mr. Harnack has undergone three serious operations in the last six months, two fingers and all the lymphatic glands of the left arm having been removed, as well as three fingers and part of the dorsum of the right hand. How far, if at all, the patient will ever be able to follow his occupation is doubtful, but his case is worthy of the most generous consideration at the hands of the public whom he has served so enthusiastically and with so much tangible benefit. It is worthy of note in this connection that the American Government granted a pension of £300 a year to the widow of Dr. Walter Reed, the organiser of the researches which demonstrated the part played by the mosquito in yellow fever, although Dr. Reed's death was not caused by his scientific work, and Bills are now before the United States Congress for conferring like pensions on the widows of Dr. J. W. Lazear and Dr. J. Carroll, who both lost their lives in experiments on the same subject. Inadequate, indeed, these sums seem compared with the pensions granted to ministers, judges, and civil servants, but we hope we are not mistaken in regarding them as the thin edge of the wedge. Scientific workers whose researches confer inestimable benefits on their fellow-creatures ought to be able to rely on their uncovenanted services being as handsomely rewarded as those of the hum-drum officials who enjoy large salaries during their active life.

Instructive Railway Accidents. A HIGHLY significant report has been issued by Colonel Yorke, the Board of Trade Inspector, on the railway accident which happened last January near Atherton, on the London and North-Western Railway. It appears from what is there set forth that a train containing passengers was being helped up an incline by an extra engine behind, the plan adopted being for this second engine to propel the train in front by a series of bumps. One of the bumps was carried out with such force that the train was partly derailed and one passenger and six company servants travelling as passengers were injured. The driver of the second engine died three weeks later of diabetes, and it came out on inquiry that the unfortunate man had suffered from the disease for a long time; in fact, that he was in a condition of debility and ill-health at the time of the accident, and in Colonel Yorke's opinion quite unfit to be in charge of an engine. "This case," adds the Inspector, "points to the desirability of more frequent medical examination of engine-drivers, especially after a man has been absent from duty for some months owing to a serious illness."

Their Prevention. WITH these wise words we fancy few will be found to disagree. We do not know what system of medical inspection the London and North-Western Railway imposes on their staff, but it is clear that it is not without loop-holes. The responsibilities of railway servants, especially engine-drivers, guards, and signalmen, are so great that only men in the pink of health and the pick of condition should be employed, and the only system by which the *desideratum* can be attained is by frequent and thorough medical examination. It is wonderful how few railway accidents do occur on British railways, but we cannot forget the terrible disasters which occur from time to time for which no cause can be found, and which can only be explained on the hypothesis that an engine-driver or signalman of many years' service suddenly forgot all that experience had taught him and behaved like a lunatic. Instances will occur to every reader. The only rational explanation for these occurrences is that the servant was ill, perhaps only temporarily, but sufficiently so to be unable to handle his lever, and not sufficiently to leave any post-mortem indications. In the case under notice the cause was abundantly apparent, and we have no doubt that disasters have over and over again been due to physical disability. It is the urgent duty to all railway companies not only to examine their employees systematically at short intervals, but to make it plain to the men that there will be no loss of wages for those on the sick-list through the orders of the Company's medical officers.

Tube Air.

Correspondence and comment has been going on of late with regard to a man who fainted in one of the "Tubes" the other day, and the purity of the air in these systems has been called in question, whilst statements showing the low percentage of carbon dioxide have been put forward triumphantly in refutation. One of the disputants has failed to be properly convinced by this demonstration, and he complains that he always has a sense of asphyxiation when travelling by tube, but modestly attributes his discomfort to "an over-active, and possibly morbid, imagination." We think he is laying undue blame on his mental endowment. While quite prepared to accept the statements made as to the low proportion of carbon dioxide, it is pertinent to point out that that constituent is only an indication of the quality of the air. It was a favourite argument in the days of steam-traction on the Metropolitan Railway that analysis of the air in the underground tunnels showed it to be as pure as that in the middle of Hyde Park, but the only result of such reasoning was to show people how very inadequate is chemical investigation for the purpose of gauging the purity of air. Tube air is, it may thankfully be admitted, an immense advance on the old Underground air, but that it is exceedingly vile is equally beyond question. Chemists and bacteriologists, and, let it be added, medical men, have yet to learn how to ventilate closed systems of rooms or tunnels, and even the plenum method seems so far to present but little attractions. Whatever analysis may show, the air on the front at Brighton is radically different from the air in a tube or any underground railway, and the problem before science is not to persuade people that they are the same, but to devise a method for making them so.

LEADING ARTICLES.

THE TITLE OF CHEMIST.

Now that the Poisons and Pharmacy Bill is again before Parliament, the question of the right of a limited company to use the word "chemists" as a designation of their business has been raised once more, and as the point is one involving important public issues, we make no apology for reverting to it. The matter has almost resolved itself into a duel between the Pharmaceutical Society and "Boots, Cash Chemists," but as we wish to discuss the principle involved, we hope to keep as clear of individual references as possible. The root of the discussion, from the point of view of medical men, is whether the public are as well served and as well protected by dealing with limited companies trading as chemists as if the business were conducted by a pharmacist himself. In the case of so-called "medical" and "dental" companies there can be, and never has been, any question. Both these methods of trading have proved to be of the most undesirable character, and when they have not been purely quack concerns, they have only engaged the services of men who have subordinated the professional to the trade element. The necessity, or the irresistible impulse, to act thus when a company's interest is concerned is universally recognised in medical circles, and the General Medical Council have very naturally ruled that it is infamous conduct in a professional respect for medical or dental practitioners to ally themselves with, or serve, such bodies. The calling of a medical man, if it is to be in the best and highest degree applied to the public benefit, compels individual and personal attendance on and attention to a patient, not with the primary idea of how large an account can be safely run up, but with the intention of restoring the patient to health with the greatest possible safety and ease. If it be argued that a company employing only qualified medical men would serve the public as well as, say, two or three medical men in partnership, the reply is, that the question is one of ideal and consequent method, and that whereas each of the medical men in a partnership is responsible solely and totally for his own acts, and that each is guided by professional opinion, in the case of a company medical treatment would inevitably degenerate rapidly into a method of money-making from which the spirit of Hippocrates would rapidly vanish. The profession would cease to be governed by high motives and generous feelings, and would be the instrument for earning money for a body of shareholders who sat at a distance and were guided only by a desire for dividends. It should thus be abundantly clear to legislators and to people generally that company-trading in medical services is obviously against the public interest, and we believe it is generally so accepted. How, then, does the chemist stand? Is he in the same position in this matter as the medical man? And must his calling equally deteriorate if he is "run" by a company? We are not prepared to say that the two callings stand on a precisely similar footing, but we have no hesitation in saying that the same argument does apply, perhaps not with the same undeniable force, but with little less cogency. A chemist, that is to say, of course, a retail pharmaceutical chemist, is, or should be, a great deal more than a mere purveyor of drugs. He is designed by his education, and by all the machinery to that end, to be the expert adviser of the medical man in matters affecting the dispensing of prescriptions, and there are few practitioners who have not had to thank pharmacists at some time or another for having saved them from committing inelegancies, or worse, in their mixtures. By virtue of his knowledge of drugs and dispensing the chemist acts as an extra check on the medical man, and is thus an additional safeguard to the public. The relationship—we had almost said the old-fashioned relationship—between the medical man and pharmacist is frequently of a co-operative character, each in his sphere working for the patient's good, and each adjusting his charges to the patient's financial position. Moreover, a chemist is himself personally responsible for the mixtures he prepares, and his error may be visited on him even by the criminal law; in fact, his own good conduct of his business is a matter of life and death to him. We are not now speaking of the abuses of their position which some chemists indulge in, but rather of the relationship to the public and to the profession which should exist, and, happily, does frequently exist, under a system of personal effort and personal responsibility; the relationship which the legislature would do well to foster by every means in its power. In the case of a trading company, even employing qualified chemists, no such relations are possible. The inducement to a company is to sell as many boxes of its own pills or as many bottles of its own "liver" mixture, and its own tooth-powders as possible, and to let the dispensing part of its business become ancillary to the quicker and more profitable trade. Indeed, the natural inducements to trade become so great that it is common knowledge that company "chemists" seek to extend their businesses by means of selling trinkets of all kinds, silver goods, Christmas presents, and even of establishing circulating libraries. In other words, it has been proved in practice what is on the face of it inevitable, that the lower, or trading, instinct is exalted, and the higher, or professional, instinct debased. The tendency of company-trading in the chemist's business is inevitably demoralising, and may, if extended, prove the ruin of good pharmacy.

CURRENT TOPICS.

Sir Henry Campbell-Bannerman.

Although it is not strictly our business, we cannot refrain from adding our voice to those of our contemporaries in rendering homage and sympathy to the distinguished sufferer who has just laid down the highest office a subject in this land can hold. We have used the word distinguished advisedly, for though Sir Henry Campbell-Bannerman himself would be the first to repudiate a comparison between himself and men of such brilliant parts as some of his immediate predecessors, it is not denied by political friends or political foes that he has been distinguished for having introduced into public life a new spirit in a new method. That spirit and that method are typical of all that is best in modern civilisation, the spirit of consideration for the feelings and opinions of others, and the method of ruling without cajolery or bullying. In no single person have these high and noble qualities been combined with such grace and in such pre-eminence as in Sir Henry, and the nation is proud to have been governed by a man who so clearly or emphatically sought not his own. In his sick-chamber it may be some comfort to him to know that what he has done for others is not forgotten, and that the warmest wishes go up from every corner of the land that his life may be spared and his health restored, so that he can enjoy the rest and leisure he has earned so faithfully and so well.

The Admission of Women to the Examinations of the Royal College of Surgeons.

The Council of the Royal College of Surgeons, England, have issued to each Fellow and member of the College, a reply post-card, requiring an answer, "yes" or no," to each of the two following questions:—"(1) In your opinion, is it desirable that women should be admitted by examination, as members of the College? (2) In your opinion, is it desirable that women, after admission to the membership, should be admitted, by examination, as Fellows of the College?" In conveying their request for replies to these queries, the Council point out that, although they have decided that it is desirable to admit women to examination for the diploma of member, and although they have power to act upon this opinion, they are nevertheless anxious, in accordance with a resolution passed at a meeting of the Council on May 9th, 1907, to obtain the views of the body corporate upon the subject Of course, it will first be conceded that the Council, in arriving at their decision, have only fallen into line with the other examining corporations in regard to the admission of women. There is, therefore, nothing very extraordinary in the step which it is proposed to take, nor can it be regarded as in any sense iconoclastic, so far as the College is concerned. Indeed, the wonder is, amid the glorious emancipation of women to which recent years have accustomed us, that the Council should only now have agreed to admit women to the examination for the diplomas which the College is empowered to confer. The fact that so far apparently women have been able to do without them, is rather an indication that the portals already available for women are sufficient to meet their requirements. It remains to be seen, therefore, what use they will make of this new accession to their avenues for qualification. Meanwhile there is little reason to doubt that the Fellows and members of the College will support the Council's decision—at all events, so far as the membership is concerned. With regard to the fellowship, some difference of opinion may possibly be expressed. Presumably, to a certain number of the body corporate it may seem rather a "large order," to use a hackneyed expression, to throw open to women the fellowship as well. And yet, after carefully considering the matter, we fail to see that any legitimate objection can be urged against this proposal if the membership be agreed to. On the contrary, there are substantial reasons why no restrictions should be placed upon women desirous of proceeding to the fellowship. For example, it would be very invidious to make any such distinction between the male and female diplomates, a distinction which neither common-sense, justice, nor fair dealing could endorse. We submit, therefore, that the examinational facilities of each should be the same, whether for the membership or the fellowship diploma. In this regard we are reminded of the old saying, "What man has done, man can do." It would, we believe, be only a short-sighted policy which would convert this saying into, "What man has done, woman is not allowed to do." This view of the matter, then, being self-evident, we shall be surprised if the *plébiscite* of the body corporate does not show an almost unanimous affirmation of the principle of the admission of women to the examinations for both the diplomas.

Consumption Treated on the Correspondence System.

The penny post is responsible for many things, some of them desirable, while others are of an obnoxious nature. It would be difficult for the wit of man to devise any more baneful system than that of medical consultation by post. The method, however, is clearly of advantage to the advertiser whose one dominating aim is to secure his patient's money at any cost. Some of these gentlemen go so far as to print a list of questions to be filled in by their victims and transmitted by post. As an illustration of the risks of such a proceeding, a more cogent example than that of consumption could hardly be taken. As every experienced medical man knows, it is often a matter demanding close and prolonged personal investigation and the exercise of the highest skill to determine the presence, the extent, and the progress of the tuberculous processes in any given case. To attempt to do so by post would be to undertake a task absolutely impossible to any human being with any due sense of moral responsibility. From an inquest held by Dr. Wynn Westcott at Poplar, on April 1st, it appears that "Dr. Alabone," who was struck off the *Register* some years ago, engages to treat consumption by correspondence. It was stated in evidence that a clergyman's wife wrote Alabone, who sent a form to be filled up by deceased, and subsequently sent medicine and pills. The fee for a month's treatment was one guinea. The Coroner pointed out that under the circumstances no valid death certificate could be procured. As a person who has had a medical training, Alabone must have known the impossibility of doing justice to the malady in question, even if its existence were ascertainable under the peculiar conditions in question, which is more than doubtful. It constitutes a standing reproach to our social system that any unregistered person should be entitled to play fast and loose with serious issues of life and death with the sole aim of acquiring money, regardless of the injury that may be thereby inflicted upon our weaker brethren. It is not a little curious, by the way, how often "a clergyman's wife" has a hand in the mischief.

Payments by Hospital Patients.

The evergreen subject of part payment by hospital patients was discussed last week at the United Kingdom Hospitals' Conference. It was introduced by the Hon Sydney Holland, who has always warmly advocated the principle involved, and has established it at the London Hospital. The motion brought forward by him and adopted by the Conference was to the effect that "where they can afford to do so, hospitial patients ought to be asked to pay for the food, medicines, and bandages supplied to them." There is, of course, something to be said on both sides of the question, and so far the balance of opinion amongst medical men has certainly not been in favour of the pay system. From the point of view of hospital boards, it is easy to understand how they would welcome what might be regarded as a legitimate source of revenue. The main question for the medical profession to decide is whether the interests of the general practitioner are likely to suffer by the creation of a form of commercial competition. So long as the payments exacted from patients are small and practically nominal probably no great hardship would be inflicted. It is only when fees approximating those payable to outside practitioners are demanded that the element of unfair competition is imported into the situation. There is some significance in the fact that although Mr. Sydney Holland's motion in favour of payment by hospital patients was adopted, it was well nigh unanimously condemned by all the medical speakers. We wonder how a resolution to the effect that, if patients pay, the medical men attending hospital patients should be paid for their services. At present medical philanthropy is freely exploited by the public and by the philanthropists, while the medical profession, both inside and outside the hospitals, is apt to receive scant consideration.

Viewing the Body.

In the House of Commons, on Friday of last week, the second reading was taken of a private member's Bill designed to do away with the practice of viewing the body by the jury at coroners' inquests. The chief clause runs as follows :—"From and after the passing of this Act it shall not be necessary for either coroner or jury at any inquest to view the body, unless the coroner, or, at the first sitting of the inquest, a majority of the jury, shall deem a view necessary"; so that, if passed, the Bill would only do away with the routine practice of viewing, but it would still leave the coroner and the jury discretion to inspect the body if they wished to do so. The reform designed is a slight one doubtless, but it is one of those constantly-recurring matters which there is a general demand for, like the Deceased Wife's Sister Act, and which should certainly be passed in the interest of the time of the House. The argument for the Bill is really one of sentiment, but it is a sentiment that is worthy of respect, and no person in his senses can consider that the perfunctory viewing which takes place at any inquest is of any value to anyone, provided the body has been identified satisfactorily by the relatives and a post-mortem has been made by a medical man. The opposition to the Bill was weak; in fact, it was only the professional obstructionist type of argument that was used against it, and Mr. Samuel accepted the second reading on behalf of the Government. In the course of his speech the Under-Secretary for Home Affairs stated that his chief had under consideration the advisability of appointing a committee to investigate the law relating to coroners' inquests, and though the points outlined for consideration—namely, the number of jurors, the methods of summons, and the holding of inquests in case of fire—are not of the most important, we may assure the Home Secretary that if his committee is also given power again to investigate the methods of death-certification, they will find ample and necessary work to do. Viewing the body in itself is a small matter, but the questions of death-certification and the conduct of coroners' courts are of grave moment to the community.

Dentists' Fees.

The case of Richardson *v.* Fremlin which created so much public interest and amusement last week is of a type which we fortunately do not hear much of, and which we are thankful to say there is seldom any necessity for. It is doubtless true that a medical man or a dentist is entitled as a private individual to fix his own charges, and equally so that there are certain people who never think they are getting good advice unless they are paying a very high price for it, but it remains the fact that there are certain understood limits to charges. A man who calls on a general practitioner at his house to consult him for indigestion knows that he will not be called upon to pay five guineas, and the same man knows that if he goes to Harley Street he will not be charged ten. Specialists' fees, are generally more fluid than those of physicians', but even the most fashionable specialists have recognised limits, beyond which, apart from special agreement, professional opinion would not support them. The jury in the case referred to seemed to take a middle course between the plaintiff's estimate of the value of his "body, bones, and blood," and the defendant's estimate of what he thought he ought to pay for the work—probably as convenient a solution as could be reached.

Open-Air Schools.

Signs are not wanting that the age of reason has at length dawned effectively upon the field of national education. The general recognition of the fact that to educate bodily defective children is to plough the sand, constitutes in itself a great advance in the science of a difficult social problem. When once that principle is admitted it must necessarily influence the whole trend of administrative education. In its broader issues it must lead sooner or later to a popular apprehension of the value of the child as an asset in the national commonwealth. In various parts of the kingdom this new gospel is being pushed to its logical conclusion in the shape of open-air schools. With the sanction of the Board of Education, Manchester has for some time past sent its poorer invalid children to the seaside in the summer. The Education Committee of the London County Council has recently made an important step in a similar direction. Two years ago a portion of the staff and children of the Homerton residential school for defective and deaf children were transfered for a month to Osen Island, Essex. The experiment was in every way a success, and the Special Sub-committee of the Council recommended that the visit should be applied to the whole of the children, residential and non-residential, and extended to a period of two months. The movement is thoroughly in touch with the humane and scientific modern tendencies, and is calculated to save the ratepayers the burden of supporting a number of broken-down individuals in later life.

The Control of Out-Patients.

Birmingham has made various attempts to deal with hospital abuses. The latest scheme was outlined by the Lord Mayor at the recent annual meeting of the Governors of the General Hospital of that town. It dealt with the reform of the medical administration and the relief of the pressure on the out-patient department of the institution. The Chairman stated that the special committee had decided to authorise the present medical and surgical staff to refer elsewhere trivial cases after giving first aid, and also to refer to general practitioners, clubs, dispensaries, or to the Poor-law authorities, chronic cases which did not require the treatment of the hospital staff. The surgical staff had been rearranged by the appointment of the casualty assistant surgeons as assistant surgeons, and it had been decided to appoint officers to deal with surgical casualty cases. Ultimately they hope to give effect to another arrangement by co-operating with other similar institutions, so as to regulate the treatment of the enormous number of out-patients. Over 60,000 out-patients are treated there annually, and there is no doubt that many are not really hospital cases, and ought to be treated by dispensaries or similar institutions. Mr. Neville Chamberlain reminded them that last year he characterised the out-patient department as the weakest part of the administration. Some definite steps are now being taken to check the inflow of trivial cases to that department. At present the scheme is only in its initial stages; but he believes they are on the eve of an important and far-reaching reform in medical administration. If the people can be induced to make small contributions, enabling them to claim medical relief as a right, and not as at present as a charity, they would, in Mr. Chamberlain's opinion, be making very real headway. The outcome of these efforts will be awaited with interest by the medical profession generally.

PERSONAL.

The Queen and the Empress Marie, on April 2nd, inspected the Alexandra Hospital for Children with Hip Disease, Queen Square, Bloomsbury.

Colonel Valentine Matthews, late R.A.M.C. (Vols.) has been made an honorary officer of the Ambulancia No. 3 (Madrid), Spanish Red Cross.

Professor Chrobak, the well-known Professor of Gynæcology and Obstetrics at Vienna, has resigned his appointment.

Sir Felix Semon, K.C.V.O., has been appointed British Government Representative at the International Laryngo-Rhinological Congress, to be held at Vienna this month.

The bungalow occupied by Dr. A. H. Wylie, Medical Superintendent of the Devon and Cornwall Sanatorium for Consumptives at Didsworthy, was destroyed by fire on March 15th.

Mr. Russell Howard, M.S., F.R.C.S., has been appointed Curator of the Museum at the London Hospital Medical College, in place of Mr. Arthur Keith, F.R.C.S.

Probate of the will of Mr. Edward Robert Bickersteth, F.R.C.S., of Rodney Street, Liverpool, and of Craig-y-Don, Anglesey, late Lecturer on Clinical Surgery to University College, Liverpool, son of the late Dr. Robert Bickersteth, of Liverpool, has been taken at £342,955.

A famous analyst has passed away by the decease of Dr. James Bell, late principal of Somerset House Laboratory, at the age of 82. For years Dr. Bell was chemical referee under the Sale of Food and Drugs Act. His work on "The Chemistry of Foods" has been long and widely known.

To-night the annual debate of the Hunterian Society will take place at the London Institution. Dr. Frederick Taylor will open the discussion, which is on the subject of "Rheumatism." Drs. Poynton, Horder and Luff have promised to take part.

The United Kingdom Hospital Conference took place on Wednesday and Thursday of last week, Mr. Charles Lupton, of the Leeds General Infirmary, presiding. The members of the Conference dined together on Wednesday evening, under the presidency of Mr. Cosmo Bonsor.

Dr. Stafford, Medical Commissioner of the Local Government Board of Ireland, and Mr. C. D. La Touche, have published an important report embodying the result of their researches into the social conditions and domestic economy of the working-class families in Dublin. We understand the report is a most valuable and interesting one, but, so far, no apparent attempt has been made to give it publicity.

A CLINICAL LECTURE
ON
THREE CASES OF "INOPERABLE" CANCER OF THE RECTUM.

By WILLIAM ALEXANDER, M.D., F.R.C.S.,

Senior Surgeon to the Liverpool Royal Southern and Workhouse Hospitals.

GENTLEMEN,—You have seen me operate upon two cases of so-called "inoperable" cancer of the rectum within the past few months, and the specimens removed, with their microscopic sections, are before you. The microscope shows that one is a specimen of adeno-carcinoma so often seen in this region, and the other a colloid carcinoma. Before I proceed with these modern cases with which you are all more or less acquainted, I wish to refer for a few minutes to a third inoperable case, and one that most of you will no doubt regard as a piece of ancient history—viz., the narrative of a case operated on by me on February 2nd, 1887. The case is reported in the *Liverpool Medico-Chirurgical Journal* for 1887, p. 235, from which I quote largely.

John G., æt. 42, a labourer, was admitted to the workhouse hospital on January 26th, 1887. The patient was very cachectic, and had lost flesh. A foul, fungating mass protruded from his rectum, and although the anus had escaped, the patient, on account of the extreme tenderness of the parts had to be anæsthetised before examination. Then it was found that my forefinger, pushed well up into the bowel, could just feel the upper edge of a cancerous mass that surrounded the lower four inches of the rectum. The case had been sent into the workhouse hospital as "inoperable" by the senior surgeon of a local hospital, who considered that colotomy was the only operation justifiable. The desperate plight of the poor fellow set me thinking, and the result was that I devised and performed the following operation on my patient, practising it several times on the dead subject before operating on the living.

Mode of Performing the Operation in 1887.—The patient, being anæsthetised, was placed in the lithotomy position in a good light, with his buttocks well raised and projecting over the edge of a hard pillow. The scrotum was held out of the way by an assistant, who was also prepared to pass a catheter into the bladder should the operator require it during the operation. The perineum was shaved and thoroughly cleansed with a solution of perchloride of mercury. The rectum, that had been well emptied before operation, was now plugged with cotton wool in order to prevent any outpouring of fæces or mucus during operation, and also to render the outline of the bowel more distinct. An incision was made in the middle line from the level of the exit of the fourth sacral nerve along the sacrum and coccyx up to within half an inch of the anal margin. From this point the knife was made to sweep round the anus. The lower two pieces of the sacrum and the entire coccyx were now cleared all round, the knife being applied closely to the bone during the process of denudation, and both the coccyx and the last two pieces of the sacrum were removed by the cutting bone forceps. By means of scissors the rectum was now detached from its surroundings, all bleeding points being promptly compressed. We were just able to reach healthy bowel without entering the peritoneal cavity. The diseased part was cut off after the proximal end of the bowel had been brought down and attached to the skin posteriorly, and afterwards as the sides of the wound were brought together, to the skin all round. The patient was carefully treated after operation by my house surgeon, now Dr. MacMurray, of Bootle, and convalesced satisfactorily.

I showed the patient, as well as the macroscopic and microscopic specimens of the growth removed at the Liverpool Medical Institution two months after operation, and in concluding my narrative of the case at that time I said:—

"I have not met with any case in my reading, as far as I remember, where this procedure is recommended or described. Mr. Cripps mentions removal of the coccyx to facilitate operation for rectal malformations in young children. In the *British Medical Journal*, March 19th, 1897, I read that a German surgeon had, with chisel, removed the left side of the sacrum before removal of the rectum, but this I did not know until some time after the operation. I do not know if the operation has been performed or recommended before, for my time for literary research is small; but whether it is a new operation or a revival, I can strongly recommend it to the profession. It is a formidable operation, and will require preparation on the surgeon's part to ensure its safe performance, but it is a remedy for the most formidable, most painful, and most disgusting disease that flesh is heir to. My first patient is, as yet, a standing testimony to its efficiency. How long he will remain so is a question that the future will settle, but he has already enjoyed two months' happiness and ease, and is almost certain of enjoying many more."

Well, gentlemen, time has completed for us the history of this case. The patient was again shown at the Liverpool Medical Institution ten years after operation. He was then working; the sphincterless rectum did not seem to give him any trouble. At any rate, he complained of none, and appeared to be quite satisfied with his condition. In January, 1908, I searched for him again, and found he had died on September 23rd, 1900, of broncho-pneumonia; duration of illness 14 days; so that he was really cured of his disease, and had his life prolonged for thirteen years, an excellent result of an operation on a case that was then looked upon as inoperable.

Such operations are now called by the name of Kraske, who first, in 1885, I believe, performed the operation of removing one side of the sacrum and all the coccyx and the sacro-sciatic ligaments on the left side so as to obtain access to the rectum. Many modifications of his operation have been made since, but they all, and mine included, are called Kraske's, and are performed in a great variety of ways, the sacrum and coccyx being often cut across but left attached by their ligaments, and then replaced after the operation is over. These modifications you will find in your text-books. I shall now describe to you what modifications I have found by experience to be most useful in my own operative practice.

In my first operation in 1887, I did not perform a preparatory inguinal colotomy. I have done this in both my other inoperable cases, and I generally do it now in all my "Kraske's." In 1887, colotomy, though a much safer operation than it had been, entailed some risks, and was not so absolutely safe as it is at the present time, and its performance was a somewhat serious additional risk. Now it is not so, and its performance is a distinct advantage. A colotomy diverts the fæces from their normal passage over the diseased mass. In consequence the diseased part shrinks in size, becomes less painful and more movable through the absence of irritation and the subsidence of inflammation. The strength, comfort and appearance of the patient consequently improve, often to a remarkable degree. In fact, many patients feel so much better that they prefer not to have any *further* operation. These are the ignorant and stupid patients, who, like the ostrich, hide their heads in the sand to avoid danger, and who will not look the stern facts in the face. In such cases, where the disease is very favourable for removal, I do without a colotomy, as I know I shall only have one opportunity given me; but in dealing with sensible people I always do a preparatory colotomy.

This temporary improvement after colotomy is a grand opportunity for preparing the patient to undergo the removal of the rectum. I generally allow a month or more to elapse between the colotomy and the excision. This gives the artificial anus time to get into good working order, and accustoms the patient to its presence, as well as allows him full opportunities to recuperate his health and strength.

I will now describe the method of removal of the rectum practised by me at the present time, and you will be able to compare it with that of twenty years ago. I only refer to cases where it is advisable to remove the anus with the diseased rectum. The patient is now generally placed on the *left side*, buttocks well elevated, and knees and hips well flexed. The skin covering the scrotum and anus is more thoroughly shaved and cleansed than in 1887, as the aseptic system has now displaced the antiseptic system then in vogue. Soap and water, ethereal soap, perchloride compresses are now more vigorously used. I now stitch up the anal opening closely and firmly with strong silk, leaving a loop of the silk free to enable me to pull upon and manipulate the bowel during the operation. The opening incision is the same, from the middle of the sacrum at the level of where it will be necessary to divide that bone right down to the anus when it sweeps right round the anal opening. The sacral and coccygeal bones are then denuded and removed as before, with the silk controlling the rectum in the left hand and scissors in the right, I snip through the muscles and fascia as they appear. An assistant on each side holds back the edges of the wound by retractors, and catches each vessel immediately it is seen either before or after it is cut. The peritoneum may be opened and the bowel followed up as far as necessary, and owing to the position of the patient the small intestines fall away and can be kept out of sight by sterilised gauze till all the diseased part has been freed all round from the healthy tissues. Then the proximal part of the healthy bowel is clamped, the diseased part cut away, and a Paul's tube tied in the proximal end of the bowel. The healthy bowel is then united high up with the edges of the cut peritoneum by fine silk, so as to shut off the peritoneal cavity from the wound, and the lower end of the bowel just above the tube is sutured to the skin by silk or silkworm-gut sutures. The sides of the enormous wound are allowed to fall together over strips of gauze that drain its depths. Few large wounds shrink so rapidly. A week makes a wonderful difference.

The inoperable case of 1887 would probably be looked upon to-day as quite operable by everyone, but my next two inoperable cases are modern, being operated on last year.

Case II.—F. H., æt. 53, a coachman.

History of Complaint.—In August, 1906, he was seized with violent diarrhœa for about ten days, having as many as 15 or 16 stools a day. This soon became reduced to 6 a day, a rate which continued unaltered for several months. About Christmas, 1906, he began to be troubled, in addition to diarrhœa, with a burning, gnawing pain in the rectum. This alarmed him more than the diarrhœa, and caused him to seek relief at a Liverpool hospital. He was there told that his disease was inoperable. His medical attendant gave him trypsin for about three months without any effect. In March, 1907, he went again to the same hospital, and was again told nothing could be done. In the meantime he was losing flesh and strength, had no appetite, the "diarrhœa" continued, the motions were composed mostly of mucus and blood, and the pain on each motion was now very severe, and at last he was unable to sit down on account of the agony it caused. His weight was now 11 st. 1 lb. instead of 14 st. 7 lb. before he was taken ill.

On July 29th, 1907, I saw the patient at the Royal Southern Hospital, heard his history, and advised his admittance in order to have a colotomy performed. This operation was done on July 30th, and the patient was left to recuperate until I returned from my holidays at the beginning of September. On my return he was much improved, was quite comfortable, the diarrhœa had disappeared, and the growths in the rectum appeared to be smaller and more movable. The operation for removal of the rectum that I have described was performed. The peritoneal cavity was opened, and a chain of affected glands which occupied the hollow of the sacrum behind the rectum had to be followed up to the promontory of the sacrum before I felt that they were all removed. This part of the operation required much patience and many ligatures, but no blood was lost. The peritoneum was now closed round healthy rectum that discharged its contents through the usual glass and rubber tube. The sides of the enormous wound fell together. A considerable amount of shock was experienced, but it soon passed away without any extraordinary remedies.

The patient left the hospital at the end of the year, having regained his normal weight, very happy and grateful, with the colotomy wound in good working order.

Case III.—The last case I will trouble you with just now is one where the prostate was affected and was removed entire, along with the diseased rectum. Such a case is by common consent deemed inoperable.

H. R., æt. 57, was admitted to the Royal Southern Hospital on October 8th, 1907, suffering from bleeding from the rectum and pain. Nine months ago the patient began to be troubled with pain in the rectum and a frequent desire to defæcate. He would be called to stool several times a day without passing anything except blood, and sometimes this passed in very large quantities. Patient sometimes has difficulty in passing water, and has to strain a long time before it comes. He sometimes passes no urine for 12 hours. No hæmaturia. Has been losing weight rapidly, and now feels very weak. On examination a hard, irregular mass encircled the lower three inches of the rectum. The anus, which was not involved, was attached rather firmly to the prostate in front; the prostate was enlarged. The case was considered to be inoperable except for a colotomy, but I reserved my decision until after that operation. Accordingly, on October 10th, 1907, a left inguinal colotomy was performed, and the fæces were completely diverted from their usual course. On December 12th, 1907, the patient had improved in the usual way. The rectum seemed more movable, and altogether the prospects seemed better. He was very anxious for radical cure, and there were no indications showing that the bladder was involved beyond the prostate. Conscious that we were operating upon a veritable inoperable case, but anxious notwithstanding to do something for the patient, we undertook the operation. The rectum was easily separated all round, but when we reached the neighbourhood of the prostate we could not find any line of separation between the rectum and that organ. We therefore snipped through the membranous urethra and removed the prostate along with the diseased rectum. Of course, a hole was made into the bladder, but this we stitched up as accurately as possible with numerous fine silk sutures, and a catheter was inserted into the bladder per urethram. The peritoneum did not require opening in this case. The rectum showed under the microscope colloid carcinoma, and the prostate malignant adenoma limited in extent and intracapsular, so that the adhesions to the rectum were the result of inflammatory action rather than extension of malignant disease from one organ to the other. The catheter, unfortunately, got out of the bladder during the first night after operation, and did not drain the bladder satisfactorily. Hence the formation of a small vesical fistula which partly closed of its own accord and required to be closed by plastic operations afterwards.

Gentlemen, I do not narrate these three cases to press you to operate on hopeless cases, but to impress upon you the seriousness of the decision that the surgeon has to make in declining to operate in any given case. The decision must be made from your knowledge of the extent of the disease, of the anatomical relations of the diseased and healthy structures, and the possibility of the separation of the diseased and healthy without so much hæmorrhage and shock as to threaten too seriously the life of the patient. The tenaciousness of the hold upon life and the vitality of the patient must be taken into account, as well as the healthiness of the system generally, so that it will not do to take shelter under an opinion taken from a text-book. The text-books resemble posts fixed in a stream, which are soon left far behind by the traffic of the river. So the opinions of our text-books are always those of the past, and the past is soon left behind in the rapid progress of surgery. But our books cannot tell us anything about the circumstances in which our individual cases are at the time that we have to decide the question of life and death in regard to them. Every such decision that we make is a new and original one. The first thing that we should try to ascertain is the bearing of the operation on the welfare of the patient. If we may reasonably hope to prolong life by an operation, then no trouble that we can take and nothing that we can do should be grudged to attain that end. The second question is the effect on the surgeon. No doubt the patient described in Case I. was very grateful to me, and all who knew of it congratulated me on the success, and to be the instrument of conferring twelve or thirteen years of life on a fellow-creature is an honour that is not often earned so clearly as in this case; but the results of such an honour are not entirely advantageous, Patients form the opinion that operations on extreme cases are your speciality, and you will be consulted by all the hopeless cases who have neglected themselves, and who are grievously disappointed when you tell them that nothing can be done A colotomy relieves even these, but they are not content with that. They find the supernatural powers they had ascribed to you did not exist, and vent their disappointment upon your character.

In all these serious operations you cannot be too explicit, both to the patient and especially to the friends, as to the prospects of the operation. It should only be undertaken, not only with their complete approval, but at their express desire.

Leaving these ethical matters, which are all-important in regard to your career as operating surgeons, I have one or two remarks to make about the operation.

First, by removal of the sacrum and the coccyx in the way described above, ample room is obtained for removal of the diseased rectum and glands with the least possible disturbance of the contents of the abdomen. The complete removal of the diseased structures should be the primary object of the attention of the surgeon. When this is finished the parts that are left can be attended to.

Second, the simple inguinal colotomy is of great advantage. It prepares the patient both locally and constitutionally for the more serious operation, promotes all important conditions of asepsis during and after operating, and most patients in my practice prefer to utilise the colotomy opening ever after as being more convenient and more controllable than the new sacral opening.

These inoperable cases will probably become less and less frequent in the future. The wider spread of diagnostic acumen will do much. The presence of diarrhœa as a clue to the narrowing of the bowel by cancer should not be forgotten. Piles, it should be remembered, are not the only source of bleeding from the rectum. In all cases digital examination should be made, so that the mistake of treating a cancer of the rectum for a year as troublesome piles should not be made. It will be made again and again unless routine examinations become the rule.

Cancer of the rectum is in my experience the least malignant of all the cancers. Its invasion of the bowel is slow and limited. Its tendency to glandular affection is not great, and is nearly always local.

I have not been able, for want of time, to trace my cases, but I know that the one recorded lived thirteen years after. Only the other day I found the address of a case operated in 1899, and learned that she was free from recurrence after nine years. Another patient died from inter-current disease three years after operation with the rectum quite sound, and all my cases had considerable relief allowed before recurrence took place. So that there is every encouragement to use our efforts in this terrible disease.

Remember that early operation is preferable to heroic operations, but these three cases show what can be done, even in neglected cases.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by J. Teissier, M.D., Professor of Clinical Medicine in the University of Lyons. Subject: "The Clinical Varieties of Chronic Rheumatism."*

LUMLEIAN LECTURES.

POINTS OF PRACTICE IN
MALADIES OF THE HEART. (*a*)

BY SIR JAMES SAWYER, M.D., F.R.C.P.LOND.,

Senior Consulting Physician, Queen's Hospital, Birmingham, &c.

LECTURE II.

MALADIES of the heart illustrate the truth that nothing in Nature is presented to us in an abstract form. While each of the four chief and well-known methods of physical examination is commonly employed by us in our examinations of the heart in practice, it would seem that those methods, in the hands of most of us, stand usually in order as to the time of their use as, first, inspection, then palpation, then auscultation, lastly, percussion. Inspection is a method by which errors of mal-observation are minimised, and errors of non-observation practically excluded. For the full use of inspection in these affections, a good light, as always, is needed, and the surfaces to be examined must be quite bared. In systematic inspection of the front of the chest, comparing the front surfaces of the two sides by sight, point by point, from every aspect, as to their size, shape, and outline, it is found that the two sides are always identically proportional in every part, in chests perfectly normal. As Walshe said, it is found that, "in perfectly normal chests the part of the walls lying to the left of the middle line, and corresponding to the heart, does not differ perceptibly in form from that placed to its right; these two divisions of the thorax are symmetrical." (*b*) In some circumstances, though very rarely, this complete bilateral symmetry may be deviated from, either as a slight præcordial excess of convexity, or even of depression, without there being proof of past or present disease of the heart. In by far the most of persons who are sound and healthy as to the heart, the impulse of the organ in its natural position is to be seen. "This spot, where the impulse is greatest, is," as Dr. Augustus Waller has reminded us, "often termed the 'apex-beat'—a misleading expression, for the true apex of the heart lies much deeper; a needle plunged through the spot of maximum impulse would pierce the left ventricle at the junction of the middle with the lower third. The cardiac impulse is not produced by the heart's tilting itself so as to strike the chest-wall; it is due to the sudden hardening and tension of the contracting ventricles, and the spot of impulse, or so-called 'apex-beat,' is simply the spot where the convex ventricular mass comes in contact with the chest-wall." (*c*) It would be more exact, in our present knowledge, to speak of impulse-beat and impulse-point than of apex-beat, and some such better diction is taking the place of the older words. Undoubtedly the systolic bulging of the ventricles is most manifest a little higher than the true apex of the heart. This bulging, in its pressure towards the anterior wall of the chest, is the main part of the impulse.

Our inspection, in an extended sense of the word, and in one especial to medicine, regards the

physiognomy of disease. It regards the characteristic appearance of the patient in particular maladies, which appearance is made up of various combinations of many constituent factors, such as size, shape, colour, and movement of parts, attitude, aspect, gestures, and so on. In many heart maladies this physiognomy is characteristic. Cardiac distress has its own form of orthopnœa, recognisable at sight, and also its Cheyne-Stokes respiration. The latter, previously noted by Cheyne, was described vividly by Stokes, with the pencil of a master, in a couple of sentences. "It consists," he wrote, "in the occurrence of a series of inspirations, increasing to a maximum, and then declining in force and length, until a state of apparent apnœa is established. In this condition the patient may remain for such a length of time as to make his attendants believe that he is dead, when a low inspiration, followed by one more decided, marks the commencement of a new ascending and then descending series of inspirations." (*a*) This striking and serious disturbance of the respiratory rhythm is found in the later stages of various forms of organic disease of the heart. It is not pathognomonic of any of these forms; certainly not of fatty degeneration, of which it was at one time held to be characteristic. It is found, too, in some cases of renal disease, sometimes of uræmic intoxication, sometimes in cerebral disease, and sometimes in tubercular meningitis. The central characteristic of Cheyne-Stokes breathing is a period of apnœa. Serious, as to the duration of life, as is the prognostic import of the appearance of this kind of disturbance of respiration, there is even an aspect of a compensatory and quasi-conservative kind in the long respiratory pause, in this waiting, as it were, of the breathing, until the feeble beats of a labouring heart can overtake it. The exact pathology of Cheyne-Stokes respiration has not been made out. Whatever may be the pathological explanation of this ominous perversion of breathing in cases other than those of failing hearts, when this respiratory trouble occurs in heart disease it may have an especial pathological basis. Perhaps it may not be too fanciful to think that, in this and in other morbidities of the heart, and in its health, too, the cardiac ganglia, with their "grey matter," may be the local centres of a kind of sub-conscious intelligence, by which some nerve-transmitted power is distributed, by the quasi-intelligent action of these little local brains, according to the circulatory needs of the moment. Perhaps we may think it likely, reasoning by physiological analogy, that, just as the depressor nerve bears from the heart an influence which passes through the medulla oblongata and causes reflex inhibition of vaso-constriction, so that blood pressure falls to suit the action of the left ventricle, so we may surmise that there may be a like communication between the heart and the respiratory centre, through which the breathing may be slowed down upon occasion, in correspondence with failing systoles; and so the apnœa becomes the physiological consequence of a syncopal stasis of the pulmonary circuit.

From a study of Cheyne-Stokes breathing I devised, some years ago, a clinical test which has been useful in practice. If we place a watch upon the front of the chest, over the middle of the sternum, of a healthy adult, who is lying upon his back, and tell him to hold his breath as long as he can easily do so, and if we time the breathing pause he makes by our watch upon his chest, we find that he will hold his breath for a quarter, or, perhaps, for a third of a minute. Sometimes in the case of a sufferer from a chronic disease of the heart in which there is a feebleness of ventricular contraction, and in which the patient is resting in bed, it will be found that the patient can hold his breath for a much longer time than a healthy person can, and that he will hold it for half a minute, a minute, or longer, and this even if his breathing be hurried by cardiac dyspnœa. This clinical fact seems explicable in the same way as was the respiratory pause in Cheyne-Stokes respiration. It appears that weak systoles of the right ventricle lengthen the time during which the breath can be held, because they permit such arrest when the blood tension in the pulmonary circuit is subnormal; such tension as compels inspiration is longer in being reached than when the heart is healthy. In cases of degenerative mural disease this test is useful; its use from time to time gives a valuable prognostic. This is not discoverable in every case of cardiac dyspnœa; but it is found from case to case, especially in cases of fatty heart, and also, perhaps, in chronic valvular disease, when compensation is failing. It seems to be a change which is allied to Cheyne-Stokes respiration, to be a lesser degree of that abnormality, evoked by a voluntary stoppage of breathing. I think it will be found upon further examination of this test in practice that in those cases in which the breath can be held longer than in health there is no blocking, or but little, of the pulmonary circuit.

We recognise a physiognomy of general cardiac suffering, apart from dyspnœa and apart from local pain, as the mark of a late stage of several forms of failure of the heart, when the malady nears a fatal ending. It is a peculiar unrest and distress, of regard, of face, of attitude, and of manner, with painful and frequent shiftings of posture. It is a physiognomy which mutely shows the obsession of a mighty dread, of a cardiac consciousness heaped up to the anguish of

"Impending horrors threatening hideous fall,"

in which there is added to the wakefulness of restlessness an imminent fear of death and even a sense of dying, with a determination to keep awake because going to sleep appears so like going to die. There is the torture of trying to keep awake to keep alive. This is a characteristic pervigilium, always of mortal purport.

By palpation we appreciate palpitation, cardiac thrills, and pericardial rubs, and examine the position, character, and extent of the heart's impulse. The push, the screwing swing, and the drop, which make up the recurring stroke of the impulse beat, are factors of that beat which our tactus eruditus may be unable to separate, for they happen together, in the same part, at the same time. But they are movements which the skilled touch appreciates, without differentiating them, in their various morbid combinations, in the differences of this impulse in disease. They are movements which make up the well-known characteristics of the healthy beat as felt by the hand, its mixed impulsive and gliding qualities, smooth, rather waving, decisive, unhasty, brief. It is impossible to describe the "feel" of the normal impulse beat; that is an experience which can only be learned in medical practice. We accept the systolic synchronism of the impulse; there is no question about it now. Synchronously with the beginning of the first sound of the heart, and synchronously with the systoles of the ventricles, the shock of the heart strikes the side of the chest. In most healthy people the impulse can be felt by palpation in the same place where is seen the visible impulse. In stout, broad-chested people no impulse may be palpable; in such the absence of it is not of itself a morbid sign. Some passions of the mind, chiefly fear, exaggerate the force of the impulse beat and widen the space over which it can be felt, and even give it somewhat of a heaving quality; what is called nervousness does the same, to less degrees. In few words the more usual of the teachings of cardiac palpation may be summed up. In adynamic diseases the impulse is weakened, and it is also weakened, or not palpable at all, when a pad of emphysematous lung covers it. The force and area of the impulse are increased when the heart is hypertrophied, and then the impulse point is variously displaced. Dilatation of one or of both ventricles, fatty change of the heart's walls or fatty loading of them, and pericardial effusions, may each lessen the force of the impulse beat, even to impalpability. Valvular thrill, the *frémissement cataire* of Corvisart and of Laennec, at first thought to mark mitral disease, is now known to be an occasional sign in any of the four valvular diseases of the left side of the heart. It seems to need for its origin a rippling current of blood, in forcible motion. In such conditions, perhaps some degree of spanæmia favours its production; a slighter thrill, but one distinguishable easily from the true valvular thrill, is observable in some cases of spanæmia alone. True

---

(*a*) "The Diseases of the Heart and Aorta." By William Stokes, &c. Dublin. 1854. P. 324.

valvular thrill always shows forth structural valvular disease. There are no statistics published as to the proportions of the frequency of valvular thrill with any of the valvular defects which it may accompany; but it seems to occur oftenest with mitral stenosis, next with aortic obstruction, next with mitral insufficiency, and least often in aortic incompetence. Valvular thrill marks valvular disease of old standing. It is one of the signs by which we discover the effects of an endocarditis of some time ago. My experience agrees with that of Walshe, who never found acute endocarditis to be attended with valvular thrill when there was certainty of the absence of old valvular disease. Later experience does not support his conclusion that "it has never been shown that nervous excitement of the heart, pure and uncomplicated, will produce thrill in people whose blood is healthy." (*a*) It is true that valvular thrill never arises as a neurotism, and that it is always a mark of valvular deformity; but there is a thrill of a softer kind which is certainly only a neurotism. A gentle, systolic thrill, somewhat tickling in quality, is palpable in some cases sometimes, when a palm is pressed over the impulse beat in nervous palpitation. Such palpitation has sometimes its own bellows sound, the *bruit de consultation* of some later French writers. One might call this thrill the *frémissement de consultation.* I think it comes and goes with the bruit, and the bruit comes and goes in half a dozen beats, perhaps in fewer: no bruit; no *frémissement.*

The College is fully aware of all the developments and refinements of cardiac auscultation which have been evolved, by the labours of many workers, since the time, now ninety years ago, when Laennec announced his discovery of mediate auscultation to the Académie des Sciences, in Paris, in the year 1818. As to diseases of the heart, Laennec declared, and, as we know, rightly, that he had discovered a "set of new signs," which were, as he called them, "certain, simple, and prominent," and such as would render the diagnosis of those diseases, to quote his words, "as decided and circumstantial as the indications furnished to the surgeon by the introduction of the finger or sound in the complaints wherein these are used." (*b*) Since that time many physicians, amongst the chief of whom have been not a few of this ancient foundation, have worked in medical practice with the stethoscope, and have traced, distinguished, and named every acoustic quality and characteristic, of the various audibilities which the play of the heart can yield in health or in disorder, of every sound which the human ear can appreciate, and of those which make manifest the origin, onset, and course of every variety of cardiac malady. Every sound of all these which our hearing can distinguish has been recognised, and has been traced to its pathological origin, to its diagnostic significance, and to its remedial indications. No other area of work within the science and art of medicine can show a progress more decisive, or knowledge more complete in its fulness, more illuminating in its clearness, in its import in our practice more significant or more helpful. This great mass of achievement, begun by Laennec, and developed by him wonderfully far from the immediate auscultation which was practised before his time, has grown and grows still, by slow experience and by the labours of many workers. Our hearing, and our sight, are our chief senses of inquisition. To our ear the examination of the heart has been opened fully.

We know the numerous modifications of Laennec's stethoscope which have been brought into use since his day, and which have been regarded often as steps in the evolution of his instrument towards perfection. In several particulars, real advances in the structure, shape and form of the stethoscope have been made. Of course, the stethoscope does not magnify cardiac sounds; it only brings them within our ken. It elongates; so to speak, our ears, gives them a medium of distant contact, and circumscribes and concentrates our hearing. For several years last past I have worked with a solid wooden stethoscope, modified in several particulars after many experiments, and I find such a one the best for auscultation, at the least, for cardiac auscultation. Acoustics, as well as practice, supports such a preference. I venture, in a very few words, to recall to my learned auditory the principles of the science of sounds which support my conclusion. The "points" of this stethoscope are: it is made of wood, of cedar wood; it is in one piece; it is about 15 ins. in length; it has an aural end of the usual shape and size; the chest end is accurately rounded to a hemisphere, with the base of the hemisphere three-quarters of an inch in diameter; the stem is tapered evenly from the chest end to a diameter of three-eighths of an inch, where it passes into the flat aural end; it is smooth but unpolished, so that it is relatively soft and warm to touch. (*a*) As to the comparative advantages, as a medium of transmission of sonorous vibrations to the ear, of a stethoscope in which the shaft is a hollow tube and of one in which the shaft is solid, it may be concluded with certainty that the teachings derivable from the principles of acoustics would lead to preference of the solid instrument. Although it has become customary to use a hollow tube in all auscultation, this subject of the comparative values of solid and tubular instruments was one of friendly scientific controversy early in the history of stethoscopy. The merits of this dispute were summed up ably by Peyton Blakiston, a Fellow of this College, in 1848, who found theory and trial alike in favour of a quite solid stethoscope. He described a simple form of such instrument of his own arrangement, and he was able to state, as he did in the remarkable chapter on the practice of auscultation in his book on diseases of the chest, that Dr. Watson, afterwards Sir Thomas Watson, whom some of us are so happy as to remember in the College, "one of the most accomplished and skilful physicians of the age," had "made use of this kind of instrument," namely, the solid stethoscope, "in preference to any other, for some years past." (*b*) Again, to take in testimony the words of a master, C. J. B. Williams, a pupil of Laennec, and himself the greatest and earliest authority on auscultation in England, and an ornament of this College, writing in 1835, in the classic Cyclopædia of Forbes, Tweedie, and Conolly, pronounced that, "it might be well for the attainment of greater accuracy in physical diagnosis . . . if auscultators would use," instead of one stethoscope for every use of the instrument, "a solid cylinder of wood for the auscultation of the heart." The science of acoustics teaches that audible vibrations are conducted farthest and with least loss of intensity, firstly, through solids, next through liquids, and least well through a gas, or through a mixture of gases.

If we compare a solid with a tubular stethoscope in practice, we can hear sounds in auscultation well with the tubular one, there being enough of solidity in its walls for a fairly good conduction of the sounds: but the pitch of the sound is higher, and so more striking to the ear, when heard through the solid one. The solid stethoscope brings out well the soft, short, low-pitched puffs of the systolic bellows sounds which mark one of the kinds of neurotic disturbance of the heart. The chest end of such a stethoscope cleanses well. A long and rigid stethoscope, 15 in. in length, has some administrative advantages in practice; one of that length is not too long for auscultatory percussion, and it is long enough to facilitate the use of that aid to diagnosis. As to the shape of the chest end, it is best rounded to the form of half a sphere. A smooth hemisphere, and one not too small, made of a kind of wood which is not too hard, as cedar, gives the shape and the material which allow of comparatively greater pressure upon the part to which the smaller end of the instrument is applied in its use, without the least discomfort to the patient, and so, one would think, of the transmission to our ear of

(*a*) Messrs. Cuxson, Gerrard & Co., medical instrument makers, of Corporation Street, Birmingham, have followed with much care my directions as to the making of a stethoscope of this description, and have produced one which is satisfactory in its use, and which I find yields improved auscultatory results in auscultation of the heart.

(*b*) "Practical Observations on Certain Diseases of the Chest and on the Principles of Auscultation." By Peyton Blakiston, M.D., F.R.S., F.R.C.P. London. 1848.

the sonorous vibrations we seek with the least loss of them in their convection. When a stethoscope is in use, comfort should be found at each end of it. There is another advantage in this half-ball-shaped end. I have wished long for a stethoscope which could be slided over the surface to which I was listening; could be slided without any breach of contact, like a ball castor, so that cardiac sounds could be the more easily traced as to the directions of their propagation. In some degree a solid chest end of a stethoscope of hemispherical shape can give such sliding, and the noise of rubbing between the end of the instrument and the patient's skin can be ended by a little smearing with oil.

ORIGINAL PAPERS.

PELVIC TUBERCULOSIS. (*a*)

By R. D. PUREFOY, M.D., F.R.C.S.I.,

Ex-Master of the Rotunda Hospital.

The Fallopian tubes take an important and indispensable part in the complex processes concerned in the reproduction of our race, and failure in the discharge of their functions, either from malformation or disease, must be reckoned one of the commonest causes of sterility. Consequently, the structure and the diseases of the tubes deserve the careful study of every practical obstetrician and gynæcologist, and though much attention has been of late years bestowed on them, our knowledge on some points remains inadequate. For instance, the condition termed hydrosalpinx appears to arise under many diverse conditions, and, according to one English writer, may even be a late stage in pyosalpinx. Again, it is at least probable that congenital malformation, or disease of the tube, plays an important part in bringing about tubal pregnancy, but writers are by no means agreed on the subject. For many reasons tuberculous salpingitis more than any other affection of the Fallopian tubes deserves careful study. Post-mortem examination shows that the genital organs are affected in 7 per cent. of all cases of tuberculosis, and the tubes in 90 per cent. of all these. The condition is generally bilateral, and in about 18 per cent. is primary, though much discussion has arisen as to how this occurs. Possibly tubal epithelium, damaged by the gonococcus, cannot resist the invasion of the bacillus, a condition homologous to tuberculous disease of the testis following gonorrhœal orchitis. Some hold that the bacillus enters the organism elsewhere, without causing changes at the seat of entrance, and settles in the tube. In most cases, however, tuberculosis of the tubes is secondary to that of other organs, and due to infection from the blood or from the neighbouring organs. Three forms of it have been recognised:—

1. A tubercular perisalpingitis, in which the serosa only is the seat of granulations.
2. A miliary parenchymatous salpingitis, in which the mucosa and musculosa are both affected.
3. A tubercular endosalpingitis, in which the mucosa alone is involved.

If the germ attacks the tubal mucous membrane in the acute miliary or chronic form, irritation and inflammation are set up, free round-celled infiltration and scattered tubercle may be observed; giant cells are scarce, as the tuberculous masses break down quickly, but the tubercle bacillus abounds. Extensive destruction of the mucosa takes place, often with infiltration of the muscular coat. In the chronic form the infiltrated plicæ swell, and through union of their edges, cystlike spaces, lined with epithelium, are formed. The tuberculous growth is often exuberant so as to simulate cancer or sarcoma; giant cells are usually detected in considerable numbers, while the specific bacilli disappear. The ostium does not always close, and sometimes the morbid contents of the tube are discharged, causing local or general tubercular peritonitis. If closure occurs, generally through peritonitic adhesions, the tube dilates, forming a pyosalpinx. It is to be remembered that such a swelling may result from a hydro- or pyosalpinx, secondarily infected with tubercle. In time, such a dilated tube may shrivel up, its cheesy contents becoming infiltrated with earthy salts; its diseased walls undergo a kind of sclerosis, through free development of fibrous tissue, constituting "salpingitis interstitialis." Frequently associated with tubercle of the tubes, though not pathognomonic of it, is the interesting condition described by Chiari as salpingitis isthmica nodosa, due to very irregular hypertrophy of the muscular coat, forming swellings, sometimes as big as a hemp seed, in the walls of the uterine ends of the tubes. They contain cystlike spaces lined with tubal epithelium, probably involutions of the mucosa. In the opinion of some writers these swellings are congenital, originating in Müller's or Wolff's ducts.

In its early stages the diagnosis of tubercular salpingitis is beset with difficulty. The tubercular diathesis and the presence of the disease in other organs constitute presumptive evidence when associated with pelvic pain, frequent, periodical, and localised, along with slight evening rise of temperature. With regard to the last-mentioned sign some important facts have been observed during recent years. In the first place there may be an appreciable degree of menstrual fever, without organic disease, as was shown by a case recorded in one of my Rotunda reports. A well-grown, healthy-looking young woman was admitted to hospital, seeking relief for grievous pain and vomiting every month, without any menstrual flux. Examination disclosed a very imperfectly developed vagina, and the absence of the uterus. During one of these monthly paroxysms her temperature reached 101° F. I removed the ovaries, which were considerably enlarged, and there was no further trouble. Some writers, such as Riebold, explain ovulation fever by the supposition that owing to the more active exchange of the body fluids at this time, resorption takes place from old pathological foci. Further observation has shown that in many, if not most, phthisical women menstruation is attended by elevation of temperature, and often hæmoptysis as well; both may be dependent on changes in the lungs, and not indicative of pelvic disease. Making all due allowance for the clinical facts, we should, in my opinion, regard with suspicion elevation of temperature during menstruation, even though for a time no other evidence of disease may be obtainable. When the disease has lasted for some time local signs of much diagnostic value may be detected by careful vaginal and rectal examination. In Douglas' space and about the utero-sacral ligaments granules and nodules may be found; and one or both tubes may be felt either contorted and thickened, or even already converted into an easily recognised swelling, with or without an adherent ovary. The interesting fact that a pyosalpinx may become twisted on itself, as happens in the case of ovarian cysts, was first pointed out on the Continent by Pozzi, of Paris, in 1897; and a few months later I operated successfully on a similar case, which is figured in my Rotunda Hospital Report for 1898, and is the first instance of this condition recorded in the United Kingdom. Some writers affirm that in tubercular salpingitis the menstrual function is but little affected; my opinion

---

(a) Paper read before the Obstetrical Section of the Royal Academy of Medicine in Ireland, March 13th, 1908.

is that in the majority of cases menstruation becomes either much diminished or much increased in amount, and in either event attended or preceded by much pain. Though many, or most, of the signs and symptoms here enumerated will be present in any given case, the disease under consideration sometimes exists when the general health and good condition point strongly to a different conclusion. In passing, we may direct attention to the fact that after tuberculosis of the tubes, tuberculosis of the fundus uteri is most frequent, and the part of fundus adjacent to the orifices of the tubes is most often affected. This was very well illustrated in a case which I saw lately, through the kindness of the Master of the Rotunda. The woman was middle-aged, in good health, and very good condition; but sterile and much troubled with pelvic pain. Laparotomy revealed the presence of general tubercular peritonitis, obliteration of the lumen of the tubes, and some caseating and calcareous tubercular masses embedded in the fundus uteri.

In August last I was consulted by a young woman living in co. Galway, on account of general delicacy and progressive loss of weight, attended with constipation and much lassitude, and inability for continued exertion. She was pale, thin, troubled with backache, and presented the aspect of one likely to become, if not so already, the subject of some form of tubercular disease. On inquiry I was told that menstruation had begun at 12 years of age, and had become too frequent and profuse; in the intervals leucorrhœa was troublesome. On making a vaginal examination I found the uterus of normal size, but pushed forward and to the right by an irregularly-shaped mass fixed in Douglas' space, nodular on its vaginal aspect, of no great thickness, and rather flattened on its upper surface. The appendages could not be differentiated on either side. I expressed the opinion that some operative procedure alone was likely to effect improvement in her condition, and consent to this was readily granted. On opening the belly the bladder was found spread over the fundus of the uterus, and extensive adhesions in all directions entirely concealed the appendages of both sides. With considerable difficulty, and in some dread of doing harm, I extricated a mass from Douglas' space, consisting of the right ovary and tube enclosing an abscess with very fœtid pus, most of which escaped during the process of removal. Continuing my efforts to loosen adhesions, I brought up the left appendages, the ovary being in a very degenerate condition, and the tube contorted and thickened. The fœtor of the extravasated pus was such that I dreaded some injury to the intestine, and was much relieved when I failed to detect any lesion of it. A gauze drain was brought out through the abdominal wound, and left in for twenty-four hours. The recovery was uneventful, and I have received excellent accounts of the patient's present condition.

On the subject of treatment there is not much to be said of an encouraging nature. It has been observed that when laparotomy is deemed advisable in tubercular peritonitis, the tubes should be carefully examined, as they may be the starting point of the disease, and the prognosis may be favourably affected by their removal; but in such a case this latter step would not be warranted unless a distended state of the organs was apparent. When the disease is only, or chiefly, in the tubes, it may still be possible to leave enough of the uterine ends to secure the continuance of their functions. In more advanced cases, where extensive intestinal adhesions are encountered, much time, skill, and patience are demanded in our efforts to secure a successful result. It is sometimes very difficult to locate the uterus itself, and it is often advisable to have it drawn up by a ligature fixed in the fundus, while we are engaged in extricating the distorted and dislocated appendages. The separation of adhesions is sometimes most easily effected by beginning from below, and it is sometimes a wise precaution to begin by tying the ovarian artery, a step likely to lessen the hæmorrhage attendant on the later stages of the operation.

GALL-STONES REMOVED FROM THE PANCREAS. (*a*)

By P. J. FAGAN, F.R.C.S.,

Surgeon to St. Vincent's Hospital, Dublin.

GENTLEMEN,—The case we have under consideration this morning merits the distinction of indicating in a marked and unusual way the pitfalls that surround our best methods of arriving at a certain diagnosis. This young woman, our patient, had the good luck of being from the very beginning of her illness, now two years ago, under the observation and care of the most skilled physicians. These gentlemen kindly communicated to me the opinions they formed of the origin and course of her present disease, and you will soon be in a position to judge how far and why they diverged from one another.

The Family Physician's View.—I look upon Miss C.'s sickness as due entirely to gastric ulcer. The ulcer is situated on the posterior wall of the pyloric end of the stomach. A good deal of thickening can easily be felt in this neighbourhood, due to adhesions to the pancreas. Local tenderness is well marked. The vomiting, which usually consists of altered food, sometimes blood-tinged, invariably sets in at that time when pyloric activity is most requisite. As the inflammation is creeping into the duodenum, causing paroxysms of pain and transient jaundice, and as I fear the danger of a severe hæmorrhage to be imminent, I recommend operation.

A Second Physician's View.—During her doctor's absence she consulted his friend, a neighbouring practitioner. He examined her on several ocasions, and told her that his deliberate opinion was that she was suffering from colic, due to a gall-stone working its way from her gall-bladder into the bowel. The hard lump in her stomach was due to a cramp of her muscles. But he pointed out that her liver was very big, and recommended an operation, as her gall-bladder he thought contained more stones.

An Expert's View.—I abstract the following from the report of this detailed examination :—"Taking into consideration the rapid and extreme emaciation, the presence of a hard, craggy tumour in the pancreas (not the stomach; the distended stomach was found separable from it), the enlargement of the liver and spleen, the jaundice increasing in intensity, the pain becoming more constant, the vomiting and loss of strength, with the passage of foul-smelling greasy stools, the disease is cancer of the head of the pancreas. The condition of the liver is secondary."

The witnessing of a paroxysm of pain determined me to explore.

Plan of the Operation.—A long cut was made through the outer part of right rectus muscle, and a transverse cut at right angles added above. The large triangular flap was turned downwards and inwards and exposed the liver—much enlarged and deeply congested—with the transverse colon tucked up close to it by a strong ligamentum hepatico-colicum, the stomach empty with remarkably prominent large veins along the curvatures, and some adhesions at the pylorus. On drawing downwards

---

(*a*) A Clinical Lecture delivered at St. Vincent's Hospital, Dublin.

the stomach, the pancreas, deep coloured, could be seen through the lesser omentum. In its head could be felt the hard-bossed tumour about the size of a medium orange. The gland was enlarged in every part. The intestinal veins throughout were distended. No peritoneal fluid was noted.

On cutting through the ligamentum hepaticocolicum and drawing the transverse colon downwards out of the field, a shrunken gall-bladder with very thick dark red walls came into view. Associated with the cystic duct, partly embedded in the liver substance and partly projecting into the foramen of Winslow, was a thin-walled swelling which promptly burst and discharged about two ounces of slightly bile-stained fluid. No induration or enlarged glands were present in the ligamentum hepato-duodenale or porta hepatis. On cutting lightly about one-eighth of an inch to the right of the descending part of the duodenum, that structure was lifted off the renal vessels and inferior vena cava, both of which appeared normal, and the whole duodenum turned as on a hinge upwards and inwards.

The common bile duct was now isolated and traced downwards to its termination. The fingers of the left hand were now placed beneath the head of the pancreas, the duodenum being received into the palm; the right hand was placed in front and the tumuor gently palpated. It rose and fell with each throb of the aorta which was resting against the left fingers'-tips. Now, in the posterior part of the tumour where the wall was thinnest the first stone was felt moving; this was pushed upwards as high as possible, cut down upon, and removed, and two others dealt with in a like manner. Thus three good-sized facetted stones were taken away. The fundus of the gall-bladder was opened, and no calculi being found in it, a metallic sound was passed down to the cavity originally filled with the stones, the cut at the end of the common duct was sutured with fine silk, the sound withdrawn, and the opened gall-bladder stitched to the skin. The abdominal wound was then closed. Bile began to flow immediately, and has continued to do so copiously ever since. The patient was able to leave hospital in three weeks. She never had a return of pain or sickness, but wishes the fistula closed, hence her presence here to-day.

I may add that though jaundice was present and the operation extensive, the bleeding was very slight, only one vessel, and that in the abdominal wall needing a ligature, and, notwithstanding that an hour and a quarter was spent in dissecting out these important structures, the patient rallied immediately.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Tuberculous Disease of the Os Calcis.—**Mr. Arthur Edmunds** operated on a girl, æt. 8, who had been suffering for the last two years from a discharging sinus on the outer side of the right os calcis. The case in question had been under treatment mainly at the Paddington Green Children's Hospital for the two years, and it was of interest as showing the value of expectant treatment in these cases. When the child was first seen there was a considerable amount of swelling and tenderness on both sides of the os calcis, and from the very first a question of radical operation had to be considered. The age of the patient and her excellent general health suggested, however, that it would be advisable to postpone operation until it was quite certain that conservative measures were useless. Accordingly, a splint with a foot-piece was applied, with the result that a good deal of the swelling disappeared. An abscess subsequently formed, however, and this was opened and scraped out. A sinus formed, which healed up after several weeks, but afterwards broke down. A second attempt was made to remove the disease by a scraping operation, but this again failed in its object and a second sinus formed on the inner side of the foot. During this time the child's health had been well maintained, and with the assistance of various societies she had spent a good many weeks of the year at the seaside. As the two sinuses still persisted, it was obvious that something would have to be done, and the child was accordingly admitted to the Great Northern Hospital. Both sinuses were freely opened up when it was found that the one on the outer side led into a cavity of the bone, while that on the inner side communicated with the first-named track by passing across the sole of the foot. This was scraped out, and gave no more trouble. With regard to the sinus which led directly into the bone, it was found that there was no evidence of any caries or necrosis of the os calcis, the healing having been delayed simply by the inability of the suppurating cavity to contract. Accordingly, the bone around the suppurating cavity was gouged away so as to leave merely a wide-mouthed depression in the side of the bone, which was then firmly packed and allowed to granulate.

Mr. Edmunds pointed out that although tuberculous disease of the bone could often be quickly and satisfactorily dealt with by a radical operation, such a method of treatment in the present case would have involved the loss of the whole or greater part of the os calcis, leading to a very considerable deformity and disability. For this reason tuberculosis of the os calcis should be dealt with in a different way to disease of the astragalus, a bone which can be excised without impairing the efficiency of the foot to any great extent. Further, there was not the same tendency in tuberculosis of the os calcis for the disease to spread, and cases such as the present often occur in which the disease is limited throughout to the one bone. It is therefore, he thought, quite justifiable to adopt an expectant attitude, to open abscesses and scrape sinuses as they form, and to keep the foot at rest, provided always that the general health of the patient is good, and that efficient antiseptic dressings can be applied over a long period.

In the present case the wound has granulated well, and is nearly healed, without any deformity or impairment of function of the foot

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, March 20th, 1908.

Dr. James Little in the Chair.

A CASE OF PERFORATION OF ŒSOPHAGUS.

Dr. Travers Smith exhibited specimen showing perforation of the œsophagus. The patient was a girl, æt. 18, who was admitted to hospital complaining that for three days she had had a sore throat, and felt very ill. Nothing could be found in the throat, except that the anterior parts were all red and swollen. There was a slight general tumefaction of the neck externally, but no particular enlargement of the glands. Temperature, 104°; pulse, 13; respirations, about 35. The patient complained of a little pain in swallowing. No conclusion was come to, except that she had some microbic toxæmia. On the day after admission he heard that she had swallowed a small piece of rasher bone, after which the sore throat began. On further examination, he found a small area of cutaneous emphysema over the lower margin of the ribs on the left side, and came to the conclusion that she had probably perforated her œsophagus with the piece of bone. A number of staphylococci were found in the blood, the emphysema became more marked, and he was able to make out some left pleurisy and a slight pericardial friction rub. They considered the question of operation, but there was no indication as to which side of the neck it should be performed on. On the fourth day in hospital she was unconscious and moribund. Bleeding and an injection of normal saline solution restored consciousness, but the effect did not continue, and she died quite suddenly. At the post-mortem the emphysema was marked, a small amount of pus and fibro-purulent material was found in the left pleural cavity, and there was, perhaps, some air in it; there was also some fibro-purulent pericarditis, and emphysema in the abdominal cavity all round the left kidney. In the œsophagus, just below the level of the cricoid cartilage there was a double perforation, one hole being a little lower than the other. Some pus around the holes was evidently the cause of the great redness, but no distinct abscesses had formed. There was no sign of a bone to be found anywhere; it had probably got softened and made its way downwards, and was possibly subsequently discharged.

CIRRHOSIS OF LIVER.

Dr. **PEACOCKE** showed a specimen of cirrhosis of the liver from a woman, æt. 46, who had always lived a temperate life. For twelve months she thought she had been getting stouter, but did not complain of illness until a fortnight before admission to hospital. She then noticed that she was getting rapidly more swollen, but her condition did not interfere with her health. When he saw her in hospital she was suffering from extreme respiratory distress; her abdomen was enormously distended and tense, and the abdominal wall was œdematous; the lungs, too, were œdematous. The apex beat of the heart was heard in the third space, and a systolic murmur was heard over it. The urine was very scanty, high-coloured, and slightly albuminous. The distention was due to fluid, which had come on with great suddenness. He had the abdomen opened and drained, fourteen and a half pints of fluid being measured, apart from a considerable amount which escaped. Drainage was continued for forty-eight hours, three to four pints being measured daily. Her condition was never satisfactory, and he had no expectation that she would do well. In her history she had no vomiting. She remained with slight elevation of temperature for a few days, and then became duller, finally lapsing into coma for forty-eight hours, and then dying. The liver exhibited was cirrhotic. The surface was nodular and extremely hard, and a microscopic section showed very advanced cirrhosis. The spleen, also exhibited, was the ordinary enlarged spleen met with in such cases. The case was interesting from the fact that it showed that the intake of alcohol was not necessary to the condition.

Dr. **DAWSON** said the contention that cirrhosis of the liver and alcoholism were not directly related was borne out by a converse observation. It had been pointed out by the late Dr. Conolly Norman and by Dr. Mott, of the London County Asylums, that cirrhosis was a rare occurrence in asylum post-mortems, although a large proportion of the cases admitted to pauper asylums were alcoholic. Dr. Mott explained the fact by saying that, owing to weakness of the nervous system, the alcohol acted on it before it had time to act on the liver. Although that explanation did not appear to him to explain the fact, the fact itself bore out what Dr. Peacocke had said regarding the view which was gaining ground—that alcohol was not the direct cause of cirrhosis.

Professor **O'SULLIVAN** said his experience was quite in accordance with Dr. Dawson's remarks. Within the last week he had three cirrhotic livers in his laboratory, in none of which was there the slightest suspicion of alcoholism.

Dr. **TRAVERS SMITH** cited three cases of cirrhosis in children, in all of which there was a distinct history of alcoholism. In a case in which the patient declared that she had never taken alcohol, he had found she was taking a "quack" medicine which was largely whiskey. He certainly thought that alcohol had something to do with the condition.

A FORM OF AORTITIS ASSOCIATED WITH SUDDEN DEATH.

Professor **O'SULLIVAN** exhibited a specimen showing a form of aortitis associated with sudden death. Some years ago he had received the heart of a young soldier who had dropped dead on the march. He was apparently perfectly healthy. The appearance of the heart struck him as being very unusual, and he observed that immediately above the commencement of the aorta, along the line of the valves, there was an abrupt rise in the surface level, which continued for about an inch upwards into the vessel, and then as abruptly descended again, forming a sort of table-land across the vessel a quarter of an inch or more higher than the rest of the surface. The left coronary artery was obstructed by the excrescence of the surface, which he took to be the cause of death. The specimen had gone astray, but he was able to exhibit a similar specimen from a young man who had been found dead a few days before in a lavatory. The condition of the heart was almost identical to the other. There was very little degeneration compared with an ordinary case of atheroma. The amount of over-growth of the inner coat of the vessel, as compared to the amount of degeneration, was enormous. There was some fatty degeneration in the central part of the big area. The orifice of the right coronary artery was practically closed; the opening of the left coronary artery was also reduced to small dimensions. A small depressed area, about an inch from the sinuses, was stained red, and found to have undergone a different degeneration from atheroma. Under the microscope was seen a great rise in the inner coat, composed of a reduplication of the inner tissue, but in the middle coat the elastic tissue was cut and torn, and split by masses of cell infiltration which ran along the course of the vasa vasorum. The natural conclusion was that both cases were syphilitics, although there was no direct evidence.

Dr. **TRAVERS SMITH** said it appeared to him that the cases differed more in degree than in kind from ordinary atheroma, and he thought it extremely likely that syphilis was the primary cause of the change in the middle coat.

Dr. **LITTLE** said that anything that threw light on the cause of death in cardiac disease was most important. He had made post-mortems on a great many people who died of cardiac disease, and in some cases he had wondered why they died, while in others he had wondered how they lived so long.

The **SECRETARY** said he agreed with Dr. Travers Smith that the difference between the condition shown and ordinary atheroma was a question of degree. Atheroma was not a very definite condition; it was rather the sum of a great many different changes in various parts of a vessel wall; and he saw no histological differences between those seen in the specimen and those seen in atheroma.

SURGICAL KIDNEY.

Dr. **MOORHEAD** exhibited a specimen of surgical kidney taken from a woman, æt. 42. Two days previous to admission to hospital she had suddenly got a shivering fit, with pain in the abdomen and vomiting. He found distinct crepitus at the base of the left lung, and rigidity of the abdominal wall, which yielded slowly to pressure. Her temperature, appearance, and respiration became typical of acute pneumonia, of which she developed further distinct symptoms later. There was some pus in the urine, and the patient suffered from frequency of micturition, from which he concluded she had also some cystitis. The dulness in the left lung gradually increased, until about two-thirds of the lower lobe had become consolidated. Her temperature ran up to 104° or 105°, and so remained for a fortnight. Her strength rapidly diminished, and she died. Bacterial examination of the pus in the urine gave staphylococcus aureus, and the sputum gave a pure culture of the same. The abdominal organs were all found to be healthy, with the exception of the bladder and kidneys. The former showed acute cystitis, and the left kidney was enormously large and studded with abscesses. The left ureter was extended and acutely inflamed. The pus from the abscesses gave a pure culture of staphylococcus aureus. The base of the left lung, instead of showing resolving lobar pneumonia, was studded with small abscesses, and showed typical septic broncho-pneumonia; the pus of the abscesses showed the same organism. The origin of the trouble was the bladder. It was the first instance in which he had found the staphylococcus aureus producing the particular group of symptoms.

Dr. **Goulding** asked if there was any evidence of endocarditis?

Dr. **Moorhead** replied that the thoracic organs, with the exception of the lung, were normal.

PYÆMIC KIDNEYS.

Dr. **Peacocke** exhibited specimens of pyæmic kidney from a man, æt. 60, who had been complaining for some years of what was called kidney disease. He was in apparently good health until January 3rd, when he noticed his urine scanty, and was becoming restless at night. On January 6th he became dull and restless, and delirious at night, and on January 11th, eight days after the onset of serious symptoms, he was admitted to hospital unconscious. He died a few hours afterwards. A small quantity of urine drawn off by the catheter contained pus and albumin. All the organs were found to be healthy, except the kidneys and bladder, which had red spots, and showed cystitis. The kidneys were not very enlarged, but there were patches showing evidence of the septic process.

Professor **Scott** said the kidneys were smooth and fairly tense; somewhat patchy on section. Under low power there were great granulations lying between the tubules locally. He got no organisms in staining by Gram's method, but with other methods some groups of micro-organisms turned up. He had no proof as to what organisms they were, as the kidney had got into formalin before he could make cultures. Nor was there any proof as to whether the cystitis was first or last.

INFECTIVE MOUSE TUMOURS.

Dr. **Harvey** exhibited specimens of infective mouse tumours obtained originally from Dr. Bashford, of the Imperial Cancer Research, which had been transplanted for five or six generations, and grew successfully in 40 to 60 per cent. of the mice inoculated with it. The tumour was found normally in mice; one tumour would be sufficient to inoculate 100 mice. The transplantations were generally difficult, and it took some time for the tumour to accustom itself to the new race. Dr. Bashford stated that when the tumours were first inoculated they generally contained a certain amount of the old stroma, which degenerated; then the epithelial elements grew and formed a tumour; but the stroma in the new mouse was taken from the mouse itself. The appearances were different in different sections of the same tumour, and varied still more in different tumours. He had worked entirely with one tumour, but there were already certain alterations in it. The tumours showed a great tendency to degenerate, and even in parts which looked fairly normal one found great fragmentation of nuclei.

Professor **Scott** said he had found hereditary tumours in certain strains of mice which grew so big that the mice died, but they looked rather like a sarcoma than an epithelial tumour, and they never showed any tendency to go back.

Professor **O'Sullivan** said the question of infiltration was a very important one. Dr. Harvey had got a tumour which went through the ribs, and it looked to him like the way an aneurysm would work through, rather than a carcinoma.

ANEURYSM OF AORTA.

Dr. **Peacocke** exhibited a specimen of aneurysm of the aorta from a man, æt. 40. He had noticed last summer a slight draw in his breathing, which, however, became better until colder weather set in. Early in December he became very breathless, with troublesome cough, and he was admitted to hospital in January. The chief physical signs were rather those of a pleural effusion than an aneurysm. The apex beat was in the third right intercostal space. No tubercular bacilli were found in the sputum. An X-ray examination showed a dark shadow over the upper part of the chest towards the left side. Examination of the larynx was impossible, as the man was in such extreme distress. He grew worse and worse, and died suddenly after a severe attack of dyspnœa. At the post-mortem they discovered the aneurysm, with an unusually large clot firmly fixed in it, as exhibited.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held on March 20th, 1908.

Dr. C. **Chapman** in the Chair.

A paper on a case of GRANULAR KIDNEY in a girl, æt. 15, probably due to congenital syphilis, was read by the **Chairman**. The patient had always been delicate, but it was not until three weeks previously that advice was sought on account of extreme difficulty in breathing and swelling of the feet and legs. The left ventricle was much hypertrophied, and the second sound at the base was accentuated: no thrill or murmur could be detected: the radial arteries were hard and thickened. The liver was enlarged nearly to the umbilicus. The urine was of specific gravity 1010, and contained 2½ per cent. of albumin and granular casts. The condition gradually became worse, and the patient died seven months later.

Post-mortem.—Both kidneys were markedly granular, the right weighing 2 oz. and the left 1½ oz. Inherited syphilis was suggested as the most probable cause of the condition found in the patient, as the bridge of the nose was depressed and the child's development was of one six years her junior, and the face had an aged aspect. There was no history of any one of the generally recognised causes of renal inflammation. The mother had had four miscarriages, while of the two children born at term, one died at 8 months from marasmus.

Dr. **Porter Parkinson** said it had long been suspected that many forms of nephritis were due to syphilis, both congenital and acquired, and to the former even in the adult. As Dr. Bradford has recently said, a large number of cases of nephritis suspected to be due to cold were probably also predisposed to by syphilis.

Specimens and drawings of a case of ACUTE PLEURO-PNEUMONIA, with extensive fibrinous plugs visible to the naked eye in dilated lymphatics, were shown by Dr. **George Carpenter**. The child, æt. 9 months, was suddenly taken ill and died of pleuro-pneumonia of the right apex in 48 hours. At the autopsy the solid lung displayed in profusion over the consolidated portion, areas which had the appearance of follicular stomatitis, and were of somewhat irregular outline. On microscopical examination these areas were seen to be made up of leucocytes and fibrin in varying proportions; the walls consisted of an endothelial lining only. In no part of them was there any alveolar structure or any suggestion of a destructive process. They contained encapsuled diplococci, and were evidently dilated lymphatics filled with the same material as that found on the pleura.

Dr. W. **Ewart** was inclined to regard the case as one of ulcerative peri-bronchitis with sub-acute broncho-pneumonia of mixed fibrinous and corpuscular type.

A case of Abdominal ballooning due to widespread Anterior Poliomyelitis was shown by Dr. F. **Langmead** in a child of 1 year and 8 months. There were evidences of a very extensive involvement of the anterior cornua which had occurred 18 months previously. The legs were useless and allowed great mobility, easily meeting behind the head. The back was sharply curved to the left in the lumbar region. The abdominal muscles were paralysed, especially on the left side, so that, on coughing or crying, two rounded protrusions were produced, due to local yielding of the abdominal wall. The delivery was a normal one.

Dr. G. A. **Sutherland** said that, in his experience, this complication was a very rare one. In this case the onset was very early, viz., when the child was 3 months old, and that increased the difficulty of diagnosis. He showed photographs in two cases which had been under his care of congenital absence of a certain area in the abdominal wall, which closely simulated infantile paralysis.

A case of Mongolian Imbecility, associated with other malformations, was also shown by Dr. **LANGMEAD**. The patient was an only child, and in addition to the characteristic signs of mongolian imbecility was the subject of (*a*) Congenital Morbus Cordis, probably due to an imperfect septum ventriculorum, and (*b*) An accessory auricle on the right side.

The **CHAIRMAN** asked whether these cases were connected with attempts made at abortion? He knew of one case in which he believed attempts had been made unsuccessfully, and the child was a mongolian idiot, though the previous three children were normal.

Dr. G. E. **SHUTTLEWORTH** said that some time ago, in trying to get the ætiology of a mongolian child, the daughter of a lady in fair position who had a contracted pelvis, he found that she had been persuaded to undergo a starvation diet in order to have a small child. The result was the birth of a mongolian imbecile at full term.

A case of

CHRONIC RHEUMATOID DISEASE

of both knee-joints was shown by Dr. F. **PARKES WEBER**. The patient, a boy, æt. 10½, had enlargement of the lymphatic glands, ankylosis of both knee-joints, and limitation of movement in the hip-joints. He drew attention to the relative painlessness and consequent insidious progress of such chronic rheumatoid affections in childhood.

Dr. **CAUTLEY** asked whether there was any evidence of gonorrhœal infection?

Dr. **SUTHERLAND** said he did not think the case was typical of any one disease. If there was an acute onset with marked lesions at 2½ years of age that was against it being pure rheumatism. He thought it was due to some septic infection which had involved both joints and heart.

Dr. **PARKES WEBER**, in reply, said that when he first saw the case it did not remind him of gonorrhœal rheumatism, and he saw no evidence of gonorrhœal infection.

Dr. J. **PORTER PARKINSON** showed a case of

TUBERCULOSIS OF THE KIDNEY WITH PYONEPHROSIS.

The patient was a girl, æt. 9. During the last 18 months she had suffered from attacks lasting a few days, with fever, headache, and pain in the left side of the abdomen. During the last attack a quantity of custard-like material came away with the urine. The liver was not enlarged, but the spleen extended slightly below the costal margin, and immediately below this, but more deeply situated, was a mass extending downwards for 2 or 3 inches, resistant and slightly nodular, with a rounded lower end like a kidney. It was dull except for the colon resonance which could be obtained over it. The right kidney was also thought to be enlarged. Tubercle bacilli had been found in the urine, which was reduced in amount, being from 12 to 16 oz. daily. It was acid, and deposited a large amount of pus; there was a trace of albumin, but no blood. During the last five weeks she had increased 6 lb. in weight, and the pus had almost disappeared from the urine.

Mr. **HUGH LETT** said that an attempt should be made to find out the efficiency of the opposite kidney by separation of the urine, and if it were working well, he would advise nephrectomy. Tuberculous affections of the kidney were often very chronic, and he had seen cases in which the disease had existed for years, the patient having gone on well under palliative treatment, but the present case seemed to be one requiring operation.

Dr. **CARPENTER** said that the bacillus could not always be found in the urine because the corresponding ureter might be blocked, as had happened in a case of his. If a case of tubercle of the kidney were seen early and there was no involvement of the bladder, removal of the kidney was satisfactory. But if the ureters on both sides and the bladder were involved, operation was out of the question.

Dr. **PORTER PARKINSON**, in reply, thought that the case would be far better treated by the ordinary medical measures than by surgery.

Sections of a Subcutaneous Fibrous Nodule removed from an infant, aged 7 months, were shown by Dr. **GEORGE CARPENTER**. The child was apparently free from rheumatism. This nodule had been removed from the neighbourhood of the angle of the left scapula, and there were also nodules in the occipital region. The nodule possessed a thin fibrous capsule, and was composed of a richly cellular alveolar tissue, free from organisms.

A case of Laryngeal Stridor in an infant of 6 months was shown by Dr. **GEORGE CARPENTER**. Since 2 weeks old it had breathed "like croup"; there was much mucopurulent discharge from the anterior and posterior nares, but the nasopharynx could not be examined digitally for adenoids. The epiglottis and ary-epiglottic folds felt normal. There was no narrowing of the glottis; the cry was natural.

Dr. **CAUTLEY** thought the proper treatment was to remove the adenoids.

Dr. **CARPENTER**, in reply, thought the present condition might be due to reflex spasm. He was not sure that there were adenoids.

A case of "Cerebral Diplegia" in a boy, æt. 6, was also shown by Dr. **CARPENTER**. The condition dated from 8 months of age. He had oscillating nystagmus; the upper extremities were weak and tremulous on use; he had never walked, and the lower extremities were adducted and stiff, and the reflexes exaggerated. He was of feeble intellect, and unclean in his habits. There was no history of syphilis or of any intracranial disorder during infancy.

A Mongol, aged 5 months, with "Congenital Morbus Cordis," was shown by Dr. **GEORGE CARPENTER**.

A specimen of "Congenital Stricture of the Left Ureter," with the kidney and bladder, were shown by Dr. **GEORGE CARPENTER**.

A case of "Juvenile Tabes" was shown by Mr. **SYDNEY STEPHENSON**. The patient, a girl, æt. 14, had bilateral optic atrophy, imperative desire to micturate, absence of one knee-jerk, and enfeeblement of the other. The family history was suggestive of a syphilitic taint, although the patient showed no personal stigmata of inherited syphilis.

A case of "Infantile Hemiplegia" in a girl, æt. 8¾, was shown by Dr. F. W. **HIGGS** and Mr. P. **TURNER**. The hemiplegia appeared after a series of fits, at the age of 10 months. There were lower facial paresis, spastic paralysis of the arm, with athetosis of the hand and fingers, and paresis of the leg with a talipes varus, which was only present when the child walked quickly, and which was probably of an athetoid nature also.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD MARCH 19TH, 1908.

The President, Mr. T. H. **BICKERTON**, F.R.C.S., in the Chair.

DR. W. CARTER gave an address on

REMINISCENCES OF FORTY-TWO YEARS' PROFESSIONAL LIFE IN LIVERPOOL.

Dr. **CARTER** remarked that, owing to recent reviews of the advances in medicine and surgery by Dr. Waters and Professor Rushton Parker during a period almost contemporaneous with the time of his residence in Liverpool, he would confine himself to a statement of some of those public controversies and events in which he had taken part. The first and perhaps the most trying was

The Contagious Diseases Acts.—Believing that these degraded both the womanhood and the manhood of the country, he was obliged to oppose them. In conjunction with the late Dr. Nevins, Dr. Ewing Whittle, and others, they established a National Association for their repeal in March, 1875, at a meeting at St. George's Hall, Liverpool, and decided to start a journal, the *Medical Enquirer*. He was Hon. Secretary to the Association and sole editor of the journal, also a purely honorary position. The work lasted until the repeal of the Acts in 1886, Dr. Nevins distinguishing himself above all others by his zeal and work.

Public Abattoirs.—The next public controversy was that concerning the position of the public abattoirs and hide market in a densely populated part of the city and very near to the Royal Infirmary. On behalf of a deputation from the Medical Institution he presented in 1884 to a meeting presided over by the then Mayor statistical tables proving the greater unhealthiness of the district than of any other district generally similar anywhere in Liverpool. This was confirmed by a subsequent report made by Dr. Stopford Taylor, the then Medical Officer of Health; and later still, in February, 1903, he was invited by the Committee of the Royal Infirmary to meet the Estate Committee and endeavour to dissuade them from renewing the lease of the abattoir. With the late Sir William Banks and Mr. Robert Gladstone, he strongly urged this course on the authorities, and trusted that this evil would ere long be removed. Dr. Carter next spoke of his prolonged efforts in the promotion of total abstinence both in Liverpool and elsewhere. Another controversy which was maintained for many years was that concerning the notification of infectious diseases without the slightest discretion being allowed in any case. He presided over a large meeting of the medical profession in that theatre in September, 1882, on the subject. After prolonged discussion and numerous meetings, a compromise was agreed upon, and the form now employed was sanctioned.

Medical Defence Union.—The attempt to persuade the late Sir William Jenner to found a Medical Defence Union, its subsequent formation by Mr. Rideal, and, later still, the Presidency by the late Mr. Lawson Tait, with Dr. Carter as a Vice-President, were mentioned, and every hearer urged to join the present ably-conducted Union. In 1870-71 the visitation of Liverpool by a severe outbreak of smallpox was the occasion of Dr. Carter's writing a series of articles in the late *Medical Times and Gazette*, after examination of all the returns supplied by the parish medical officers in charge of the public sheds. The mortality was strikingly the inverse to the number and size of the cicatrices. Many years later, therefore, when the practice of some medical men had arisen of making one small pin-prick and terming that efficient vaccination, he felt bound to bring the matter before the Lancashire and Cheshire Branch of the British Medical Association on February 28th, 1889, at which a resolution adverse to this was come to at a large meeting.

The Congo Atrocities.—On March 23rd, 1904, at a large public meeting held at the Philharmonic Hall under the Presidency of Mr. Emmott, M.P., the Bishop of Liverpool proposed, and Dr. Carter seconded, resolutions which had the effect of starting the Congo Reform Association. As Chairman of the Professional Sub-Committee of the Tropical Diseases School since its formation, he felt much embarrassment at times owing to his having to protest against the extravagant laudation in the annual reports of the school of King Leopold of Belgium, and when invited to accompany the President of the School and some of his colleagues to Brussels to luncheon with the King last August twelvemonth, he was obliged to refuse the invitation. He did not blame those who went, nor the gentleman who sent him the invitation, but he never could have ceased to blame himself if he had gone, nor to feel indelibly disgraced.

Midwives Bill.—When the midwives registration controversy arose, he felt bound, under the conviction that many humble homes were wrecked through the spread of pureperal fever, owing to the carelessness of uneducated and ignorant women, strongly to support the Bill for the education and registration of midwives. The matter was very hotly discussed on May 11th, 1894, at a large meeting held in that room, when his motion on the subject was lost by a large majority. He published his speech, copies of which were requested by the Royal College of Physicians for their library table, and finally, as everyone knew, an Act was passed in 1902 compelling the education, certification, and supervision of all women practising as midwives.

Generous Liverpool.—Dr. Carter lastly drew attention to the generosity and public spirit of the wealthy men of Liverpool, especially mentioning Mr. Sutton Timmis, who after the death of his wife communicated to Dr. Carter through his friend, Mr. Wade Deacon, his desire to place £10,000 in the hands of trustees for promoting a cancer research, over the committee for carrying out which he (Dr. Carter) had presided, and still continued to preside as Chairman. He mentioned other splendid acts of generosity on the part of the same gentleman, and finally spoke of the extraordinary response to the appeal made by himself a few years ago for the family of the hero, Dr. Smyth, Liverpool contributing hundreds of pounds. Rich and poor alike gave, one poor man sending twopence, another sixpence, a poor dressmaker beseeching to be allowed to make clothes for the children, and overjoyed when allowed to do so; but no class contributing so generously or so generally as the medical profession, who alone could estimate the great risks and the noble way in which that heroic man, like a true soldier, had met them.

A hearty vote of thanks, proposed by Dr. Macfie Campbell, and seconded by Mr. Rushton Parker, was accorded to Dr. Carter for his excellent address.

The meeting on Thursday, March 26th, 1908, was entirely devoted to the exhibition of clinical cases.

Among those of special interest were two by Dr. H. R. Hurter—(1) Acrocyanosis chronica anæsthetica (cum gangrena) a condition allied to Raynaud's disease and erythromelalgia. Male, æt. 35. (2) Female, æt. 23, with congenital morbus cordis and defective physical and mental development. Height 4ft. 7in. Has been under treatment for hysteria.

Dr. A. Gordon Gullan—(1) Raynaud's disease, male, æt. 56. Previous attack eight years ago, lasting 12 months. Note: Typically red, congested face, swollen purple (asphyxial) condition of fingers and toes, soles of feet, ears. (2) Myxœdema, woman, æt. 55, Menopause at 50, disease developed gradually, since typically. Note: swollen face, malar flush, glazed dry skin, large swollen tongue, spade-like hands, subnormal temperature, infrequent feeble pulse.

Dr. Percy Marsh—(1) A case of meningitis in which Calmette's reaction was positive, the cerebro-spinal fluid showed lymphocytes, did not reduce Fehling's solution. Treatment, Koch's tuberculin (T.R.) recovery. (2) An infant with chronic basilar meningitis. Symptoms: marked retro-colic spasm, rigidity of extremities, tremors, no optic neuritis, cerebro-spinal fluid turbid ("polymorph" leucocytes), no reduction of Fehling's solution. No organism by culture.

Mr. Hugh E. Jones showed two ear cases—(1) W. P. R., chronic suppurative otitis media with granulations. Headache, giddiness, pain, diplopia, optic neuritis; watch heard on pressure only, bone conduction exaggerated. Complete postaural operation. Healing with disappearance of all symptoms and return of hearing. (2) A.W., æt. 52. Acute suppurative otitis media without perforation of drum membrane. Acute apical mastoid abscess (?) primary, with extension into neck and exposure of dura mater of posterior fossa and the sigmoid sinus. Operation, March 4th.

Dr. John Hay—(1) Pseudohypertrophic paralysis in a man, æt. 23. (2) General paralysis of the insane in a woman, æt. 30. No history of syphilis. (3) Locomotor ataxia and general paralysis of the insane in a woman, æt. 40. No history of syphilis. (4) Youth, æt. 20, illustrating stunted growth from heart disease in early life.

Some surgical cases were shown by Dr. R. W. Murray, Mr. Keith Monsarrat, and Mr. J. F. Edmiston. Interesting skin cases were exhibited by Drs. Stopford Taylor, R. W. McKenna, and Dr. Leslie Roberts, and various ophthalmic cases by Mr. A. Nimmo Walker.

A demonstration was subsequently given in the theatre of Lumiere's colour photography as applied to fresh pathological specimens, illustrated by seventy lantern slides, including human and comparative pathology (macroscopic and microscopic), by Mr. G. Hamilton.

ULSTER MEDICAL SOCIETY.

Meeting held Thursday, April 2nd, 1908.

The President, Dr. John McCaw, in the Chair.

The Hon. Secretary, Dr. **Howard Stevenson**, read the report of the Committee on Hospital Abuse, and it was agreed that the resolutions of the Committee should be printed and circulated among the members, and considered at a meeting on April 16th.

Mr. **Fullerton** showed a patient who had suffered from a fracture of the fore-arm, and in whom the bones failed to unite and the arm was useless. After other methods had failed, Mr. Fullerton riveted the bones, and the union was now perfect. A radiograph showed very beautifully the bones and the rivets.

Dr. **Dempsey** read notes of a successful case of Cæsarian section. The patient was a woman, æt. 27. She had had two previous pregnancies, both terminated by craniotomy. On examination the true conjugate was found to be 2½ ins. She stated that she was the ninth of eleven children, that she had been nursed on the breast, but had developed rickets. She was 5ft. high, and bandy-legged. Dr. Dempsey advised Cæsarian section, and admitted her to hospital and prepared for operation on December 23rd, two days before confinement was due. He operated on the appointed day, Drs. J. B. Moore and McLorinan assisting, and the operation proved easy and the loss of blood almost nil. Recovery was uneventful, and the mother and child were discharged in a month, both well. Dr. Dempsey concluded with some remarks on the relative advantages of this and alternative operations.

Dr. R. J. **Johnstone** said that he had done two cases, the first in a woman suffering from inoperable cancer, who became septic and died in a few days; the second successful. He did not think pubiotomy was justified with a conjugate of less than 3 in.

Dr. **Hicks** also spoke, emphasising the simplicity and safety of the operation in suitable cases.

Dr. J. H. **McKee**, of Harrogate, read a short paper on "Harrogate and its Treatment," in which he described the various springs and the therapeutic uses to which they were put.

Drs. Dempsey, McKisack, Davison, Kevin, and the President discussed the paper.

Dr. **Cecil Shaw** read a paper on "Squint in Childhood," based on notes of over 300 cases. Dr. Shaw said that he did not purpose to discuss the highly technical question of the causation of squint, but just pointed out that it was always associated with errors of refraction, and that its successful treatment was attained by the early correction of those errors. In his 326 cases hypermetropic astigmatism was present in 79 per cent., hypermetropia in 19 per cent., and mixed astigmatism or myopia in 2 per cent. only. In no less than 16 instances more than one member of a family was affected. While 75 per cent. of cases appeared before 5 years of age, only 30 per cent. came for treatment before 5, most cases being neglected till the sight was found defective at school. There was great difficulty in following up hospital cases, which were apt to cease attending when cured, but he had been able to follow up about 50 per cent. of his cases, and found among these that treatment with glasses and atropine resulted in the cure of 50 per cent. and the great improvement of 20 per cent. If the optical treatment did not result in cure in a year or so, and if there were good vision in the squinting eye, a tenotomy or similar operation might do good, but was not to be advised otherwise, he thought. After 7 per cent. operation a further 7 per cent. were cured and 3 per cent. improved. When the squint was treated while still occasional, before it became fixed, the results were still better, 74 per cent. being cured and 22 per cent. improved. The chief point of the paper was to call the attention of the family practitioner to the immense advantages of the early treatment of squint, as in that way the squint could most likely be cured without operation, and the sight of the squinting eye would be preserved from slow deterioration. This desirable result could only be attained by the co-operation of the family doctor, who usually saw the case in the early stage. In concluding, Dr. Shaw emphasised the fact that children suffering from squint are medical cases, to be treated by medical men, and ought not to be allowed to fall into the hands of the prescribing optician or any other quack.

Drs. Killen, Cunningham, MacIlwaine, and the President discussed the paper.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, April 5th, 1908.

Hæmoptysis.

The treatment of hæmoptysis is simple enough, consisting in three drugs administered, combined or concurrently—ergotin, hippo and adrenalin.

The patient, kept in a horizontal position, the head low, without a pillow, is enjoined to absolute silence. The ice-bag is placed on the chest, and mustard leaves to the calves of the legs, while hot bottles are applied to the feet.

The ergotin can be given subcutaneously, and at the same time 2 grains of hippo every quarter of an hour until nausea sets in, while iced and acidulated drinks are given moderately.

Adrenalin is a good adjuvant, and may be combined with ergotin as follows:—

Ergotin, ½ dr.
Sol. of adrenalin, 6 drops.
Tincture of digitalis, 12 drops.
Tincture of cinnamon, 1 dr.
Cognac, 1 oz.
Syrup, 1 oz.
Water, 4 oz.

A tablespoonful every 2 hours.

Erythema of Infants.

Erythema, or dermatitis, resulting from the contact of the epidermis with the urine and fæcal matter, is at first limited to the buttocks, and finally extends to the thighs, legs and back. It is easily cured when taken at the outset by washing with some astringent infusion (walnut leaves) and the application of an absorbent powder (subnitrate of bismuth).

Where the affection is chronic the treatment is not so simple. The cause of this dermatitis is to be found in gastro-intestinal disorders, consequently attention must be paid to the feeding of the children in regulating their little repast, which is frequently sufficient to cure the affection.

M. Quillier recommends washing the parts each time they are soiled with absorbent cotton and boiled water, and, when dried, applying a mixture of fuller's earth, subnitrate of bismuth, and oxide of zinc. Ointments are generally irritating.

Treatment of Purulent Ophthalmia.

The classical treatment of purulent ophthalmia of infants by nitrate of silver has been abandoned by Dr. Westermann, who obtains the same results from the more gentle method of instillations of argyrol—

Argyrol, 10 gr.
Water, 1 dr.

Three drops are instilled into the eyes every three hours. After 48 hours of this treatment methylene blue is substituted—

Methylene blue, 1 gr.
Water (sterilised), 1½ oz.

Four drops, every four hours, between the eyelids. After two or three days of this treatment, finely powdered iodoform is blown into the inferior cul-de-sac twice a day for the space of two days, after which 1 drop of laudanum is instilled every morning for eight days, completing the treatment.

Treatment of Obesity.

The treatment of obesity is, above all, hygienic, but certain therapeutic means come in as adjuvants.

Purgatives hold the first rank. Stout persons are generally constipated through sluggishness of the liver and atony of the intestine. Saline purgatives are particularly indicated, and might be given once a week.

The use of alkalines, such as bicarbonate of soda or mineral waters are indicated for their stimulating effect on the diverse arthritic manifestations.

The administration of iodide of potassium enjoyed great favour for a long time, but to-day it is practically abandoned in the treatment of polysarcia. It is useful, however, in concomitant affections (asthma, rheumatism deformans, arterio-sclerosis). The thyroid treatment, which gives such remarkable results in myxœdema, suggested the idea to Leichtenstein, Wendelstadt, Bourneville, of treating obesity by the same method, and brilliant successes were recorded; but after repeated trials it was discovered that the thyroid treatment was not favourable to every case, and, on the other hand, its prolonged use was not without danger.

Without rejecting completely this treatment, which may be suitable to certain varieties of obesity, it should be prescribed with caution.

The thermal cure should not be neglected when possible—Chalet-Guyon, Vichy, Marienbad, Carlsbad, Kissingen, Hombourg—completed by massage, exercise and sudations.

GERMANY.

Berlin, April 5th, 1908.

At the Society of Surgeons, Hr. Rinne discussed the
Differential Diagnosis of Typhlitis and So-Called Disease of the Appendix.

Since, some years ago, having a case under his care in which the diagnosis was for a long time doubtful, and which at last turned out to be one of appendicitis, his interest had been aroused in the subject, and since that time in making gynæcological examinations, in all women suffering from perityphlitis—a total of 370—he had ascertained that amongst this number 41, or 11 per cent., had some affection of the genital system. In one-third of these there was no appendicitis; the diagnosis was therefore wrong.

As regarded differential diagnosis, the history was to be considered first. If the disease was bilateral, it was probably an affection of the adnexa. If the tumour was high up on the pelvic wall its origin was probably the appendix; if it lay around the uterus it would be adnexal. If general peritonitis was the first thing noticed, then the seat and character of the pain, the tension of the abdomen, and the course of the disease would be considered. That one was liable to errors in the consideration of these points was shown by two cases in which a ruptured tubal pregnancy was mistaken for peritonitis from appendicitis. The diagnosis was often, therefore, very difficult, and even impossible; but it was always well to treat the case as if perityphlitis was present—*i.e.*, to operate in doubtful cases.

Hr. Müller suggested that the pain zones of the skin of the abdomen should be utilised in coming to a conclusion, as those of appendicitis were different from those of disease of the adnexa.

Hr. Gottschalk was of opinion that the pain gave no clue as to diagnosis. This would be more difficult in chronic cases, especially when there was an acute exacerbation in the course of chronic disease of the adnexa, a mistake could easily be made. A very accurate examination would prevent errors.

Hr. A. Pincus communicated a note on
Therapeutical Attempts with Trypsine and Amylopsine
in inoperable malignant tumours. No harm was done by the treatment, nor any good. Post-mortem examinations showed no characteristic changes. In two cases of extensive tuberculous glandular disease of the neck, one in an adult and one in a child, there was some retrogression of the disease in the glands but no recovery.

Hr. Seefisch showed a case of
Volvulus of the Ascending Colon.

The patient was a working man, æt. 45, who for a long time had suffered from pain in the stomach after eating, and who was suddenly taken ill on January 11th with violent pain, vomiting, and collapse. The abdomen was of boardy hardness, the most tenderness on pressure in the right side. In the belief that the case was one of perforation of the vermiform appendix, an operation was performed the same night. Some odourless exudation was found in the abdomen. The cæcum and vermiform appendix were not in their usual place, but the speaker found a tense tumour to the left of the incision. After enlarging the incision this was found to be the twisted and displaced ascending colon, which was swollen and of a blue-red colour. The vermiform showed no other changes. The twisted loop, the mesentery of which was very long, was untwisted. During the toilet of the peritoneum some peppercorns came into view, and on further search a perforation of the anterior wall of the stomach not far from the pylorus. This was stitched round and over, and the abdomen well washed out and closed. Recovery was uninterrupted. The speaker thought the perforation was the first occurrence, and the volvulus the result of the vomiting.

Hr. Seefisch also showed a youth, æt. 19, who fell from the second storey of a house and fractured the first lumbar vertebra. There was paresis of both legs and transient paralysis of the bladder, which required the catheter on two occasions. He had pain in the left side, which in the course of six weeks amounted to violent colic. Röntgen illumination showed two concretions of the right ureter. The ureter was now opened and the concretions removed, the ureter being again closed. Recovery.—There could be no infection of the urinary passages that led to the formation of the concretions. There was probably a causal connection between the fracture of the vertebra and the calculi.

At the Medical Society Hr. Klapp spoke on the
Treatment of Phlegmons of the Sheaths of Tendons.

He pointed out the indifferent results that had been obtained even in recent times. He claimed that better functional results were obtained by the Bier method—*i.e.*, by smaller incisions and permanent stasis. By following this plan the function of the tendon would be retained in about half the cases. The idea had occurred to him that as good results might be obtained by the small incisions without the stasis. In a series of cases he had omitted the latter, and had made small lateral incisions in the fingers, sometimes as many as four, and had been satisfied with the results obtained.

AUSTRIA.

Vienna, April 5th, 1908.

Cutaneous Absorption.

At the Gesellschaft, Oppenheimer related his experiments on normal and pathological skins to determine the amount absorbed by the skin in disease and health. The substance used was jothion, which is absorbed rapidly when the skin is in a healthy condition, appearing in the urine in less than one hour after application.

In cutis atrophia idiopathica the drug is long in appearing in the secretions, and very scanty when it does appear, four hours at least after painting on the skin. In scleroderma universalis with a histological epidermis the rigid deposit in the cutis narrows and almost closes the vessels as well as the sebaceous and sudatory ducts which diminishes and delays the absorption more than an hour and a half, but this retardation is even less than it is in the atrophic skin. The glands of the skin seem to play an active part in this absorption, and to determine how far these participated cases of lichen ruber acuminatis universalis, ichthyosis congenita universalis and syringo cyst adenoma were acted on; but, strange, all these did not differ much from the normal condition. Hyperkeratosis and parakeratosis, which affect the follicles and sudatory glands, do not affect the absorption. On the other hand, there is a distinct difference of absorption in the smooth bald skin and that densely covered with hair. In the bald head the jothion is absorbed very slowly, while the hairy head takes it up greedily. It seems the epidermis plays an active part in the absorption from the diffusion effects of that structure more particularly on the sebaceous glands.

Röntgen Rays and Epilepsy.

Robinsohn gave a few examples of epilepsy, and expounded a new method in the *technique* of cerebral radiology whereby a number of our blunders may be avoided. He exhibited a case of traumatic epilepsy where the Röntgen rays exposed a shadow about the size of a walnut, lying in the upper part of the cerebral hemisphere and having every appearance of an alveolar tumour. To remove the deception many examinations must be made, with varying results. To avoid this Robinsohn uses two sensitised plates, which he calls the double method, wherein the weak and the strong, exposed by the same light can be brought into contrast. By this means the imperfect shadow is greatly reinforced and the morbid condition more accurately observed. Benedikt said he had recently diagnosed several epileptics with the Röntgen rays, but at first he had to confess there was much confusion in his mind with the Pacchionian cavities in the vault of the cranium, where a grey cloud seemed to linger. This nebulus which he showed, was not a traumatic affection, but rather a neoplasm. In another case of a traumatic nature this nebulus was found in a rhomboid or longitudinal depression in front of the sagittal suture. In front of this depression a spoon-like spicula of bone could be seen protruding. The patient complained of severe spasms in the toes of the opposite side of the body.

Redlich thought all these diagnosis very ingenious, but he had to confess he could not diagnose genuine and symptomatic epilepsy by means of the Röntgen rays. He then related two cases to prove his scepticism. They were both diagnosed by the rays as symptomatic epilepsy, but at the post-mortem the one had tubercle in the left frontal lobe of the brain, the second had an extensive glioma in the same region. There was great danger in relying too much on the Röntgen rays in cerebral disease.

PHYMOSIS.

Pollak, from Prague, gave a description of a method which he practises in relieving phymosis in the infant. He does not circumcise, but makes a longitudinal incision back to the corona. He then pushes all back and puts a few stitches in the wound and leaves it to heal, which it does with excellent results.

BLOOD-LETTING IN NEUROSIS.

Theilhaber is a firm believer in bleeding for the relief of neuralgia and other pains in gynæcology. He tells us that we bleed for renal diseases, uræmia, cerebral diseases, poisoning by gas, etc., and why not relieve the tension in neurosis. Dyes relates cures by bleeding in lead poisoning, others avert eclampsia by the same means, while Eversbusch relieves ophthalmia by the same method.

The indications for relieving neuralgia is when the blood tension is high. The same may be performed with pain in the abdomen, cephalalgia, sleeplessness, arthritis, and the climacteric period. Scarification of the portio will relieve nervous metrorrhagia, atonic hæmorrhagic metritis, or persistent bleeding when the vascular tension is high, but is contra-indicated in chlorosis.

HUNGARY.

Budapest, April 5th, 1908.

The Secretary of the Society of Dermatologists has lately read a paper on the progress of the prophylactic study of syphilis of late years. He said that there was renewed activity in this direction among the medical profession in recent times. The reasons were not an increase in the number of cases, nor a more severe course of the disease, but better statistics and the discovery of the bacillus of syphilis. The spread of syphilis could be limited by means which applied to the general public and the individual. The former included control of prostitution, but had proved a failure. Impracticable also was the suggested compulsory report of cases by physicians. A better measure was the education of the public as to the nature of the disease. Instructions should be given how to avoid infection innocently. He made a plea for increased facilities for treatment in hospitals and dispensaries. The Secretary, Dr. Huber, thought that at the present time the most valuable prophylaxis against syphilis ought to be practised by the medical profession in their relations with their patients. Since no methods were known to abort the disease after infection occurred, the most important duty was a thorough treatment.

At the recent meeting of the Medical Society, Dr. Kubinyi read a paper on the

CLEANSING OF THE VAGINA.

He said that the question of the preliminary cleansing of the vagina has been dealt with exceedingly much, and still is not yet satisfactorily settled. So much is true, that the cleansing of the vagina has a decided bearing on the morbidity of the puerperium. He bases his conclusions on statistical and bacteriological investigations. Three per cent. solutions of creosol were employed for the irrigations, and he absolutely denies that any disinfectant effect can be obtained with the 1 per cent. solution. The average number of cases in which no rise of temperature occurred during the puerperium was usually about 68 per cent., while during the two years in which no irrigations were employed this number sank to about 53 per cent. In the operative cases in which the cleansing was more complete and thorough, the number of cases in which no fever was present was even greater than the average. In a number of instances in which streptococci were demonstrated in the vagina before douching, a marked decrease in the quantity of growing organisms was noticed within a few hours after the irrigation had been given. The writer claims that if such a procedure is attended by the good results mentioned, there is no reason why it should not be employed, provided that it is not attended by any harmful results, and he does not believe that such occurs in the method advocated.

Dr. Lesner reported a case of

POISONING FROM POTASSIUM CHLORATE.

The patient, a man, æt. 27, purchased at a drug store a bottle containing fifty 30-centigramme tablets of potassium chlorate. Though the printed directions were to dissolve one tablet in the mouth every hour or so, the patient used the entire 50 during 18 days. On the nineteenth day the patient complained of itching, and after three days the trunk, forearms, wrists, thighs, legs and ankles were seen to be covered with innumerable reddish macules. There were also numerous petechiæ. There was no nausea, diarrhœa, or headache. The patient made a slow but uneventful recovery.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

The University Bill.—The chief interest of the week has, of course, been the appearance of the long-promised University Bill, and on all sides it is discussed with the greatest vigour. Naturally, there are differences of opinion, but on the whole medical opinion is decidedly in its favour, and this is specially true among those who have had any experience in educational affairs. A few irreconcilables, members of the association run by the late Dr. McKeown, have maintained their principles by cursing the Bill from the first report of its conception all through its period of gestation, and it is hardly to be expected that they will be silenced by its appearance; but their opposition was looked for, and is not counted of much importance. The fact, too, that it is opposed by certain politicians does not dismay its friends, for such opposition is loked on as merely a show of fight to satisfy election pledges, and whatever weight it might carry is fairly neutralised by the fact that the leading business men of the city are strongly in its favour. The Belfast Medical School has made great advances of late years, and there are a large number of young men connected with it who feel that if we are left to work out our own ends in University matters we can establish a strong and successful school with a degree that will command respect wherever Ulster men go. The raw material is excellent, as has been stated again and again by teachers from other schools who have come to Belfast, and if a properly equipped school is provided by Government and private generosity, and a high standard maintained by examiners, there is no apparent reason why these high aspirations should not be realised.

LETTERS TO THE EDITOR.

CONJUNCTIVITIS NEONATORUM.

To the Editor of The Medical Press and Circular.

Sir,—There can only be a general agreement with the editorial views which you express in your last issue upon the above subject. Nevertheless, it has been and is maintained that the term "ophthalmia" is a group name which should be retained on "practical" grounds, inasmuch as inflammation of the conjunctiva in the new-born is produced by a variety of morbid germs. Just so, however, is it in the case of conjunctivitis of the adult. In both the causes of the disease are in every way identical. Moreover, at least 90 per cent. of the cases of conjunctivitis neonatorum are due to gonococcic infection. How absurd, therefore, it is to describe them as purulent "ophthalmia," when the same disease in the adult is properly designated purulent conjunctivitis. As you rightly surmise, the newer generation of ophthalmic surgeons will probably recognise that there are no "practical" grounds for the retention of such an unscientific anachronism as "ophthalmia."

I am, Sir, yours truly,
Percy Dunn.

Wimpole Street, London, W.

A QUESTION OF FEES.

To the Editor of The Medical Press and Circular.

Sir,—The extraordinary case which came before the law courts last week, in which a dental surgeon sued the husband of a patient for £570 for work performed on his wife's mouth, suggests to me that the time has come for the whole subject of fees to be considered by medical men. Surgeons' fees have grown to an exorbitant scale, and there is a widespread distrust of them by the public on that account. Some of the specialists have destroyed the good name of the profession by their excessive fees, by their general rapacity, and the way they send patients from one to the other. On the other hand, the physician, whose art is, I consider, the more scientific and infinitely more difficult, is being crushed out of existence, while the general practitioner at the other end of the scale is being starved on fees that amount in pence to the surgeon's and specialist's fees in guineas. (Moreover, the general practitioner often loses his patients, who are annexed by the consultant or specialist.)

What is to be the remedy? Are we to look to a higher standard of education for the general practitioner, with the rising tide of post-graduate instruction as a final touching-up? Or are we to be driven on the principle, *Ut quimus, quando ut volumus non licet*? I am hopeful that the former will be the ultimate virtue.

I am, Sir, yours truly,
G. P. T.

OBITUARY.

WILLIAM WOOD, M.R.C.S., L.S.A.

Dr. William Wood, whose death we regret to announce at Garton-on-the-Wolds, near Driffield, was for many years a familiar figure in the East Riding. He passed through his medical course in London, Glasgow, and Paris, and at one time held the appointment of Demonstrator in Anatomy at Glasgow. While continuing his studies at King's College, London, he was attached to the residential medical staff at King's College Hospital, and during that time he devised a surgical appliance for the treatment of excision of the knee-joint. In 1857 he became a member of the Royal College of Surgeons, and about that time he succeeded his father in an extensive practice at Middleton. He acted for over 40 years as Medical Officer to the Driffield and Beverley districts, and also held other appointments. Dr. Wood was possessed of a keen sense of humour, and during his professional experiences, which lasted over 50 years, had ample opportunity for the collation of a rich fund of anecdote and reminiscence. He was an enthusiastic sportsman, a good shot with a rifle, at one time a follower of the Holderness Hounds, and for 25 years a member of the Derwent Anglers' Club, Scarborough.

SURGEON-CAPTAIN J. NESBITT PATTERSON.

On Thursday last, Surgeon-Captain Patterson, of Earlestown, Lancashire, succumbed to an attack of influenza, after only three days' illness. The deceased gentleman qualified in 1878, having studied at Queen's College, Belfast, and the Ledwich School of Medicine, Dublin. He went thence to Earlestown and built up a lucrative practice. He was a member of the local Urban Council, and only a few days ago was re-elected without opposition an overseer of the poor and chairman of the Warrington Board of Guardians. He also occupied the post of Surgeon-Captain to the 1st V.B.S. Lancs. Regiment.

SPECIAL ARTICLES.

THE NEW UNIVERSITY BILL.

Mr. Birrell's long-promised University Bill for Ireland was introduced on the 31st ult. and received with almost universal approval. His scheme proposes to establish two new Universities—one in Dublin and one in Belfast. The University in Dublin will take the place of the Royal University, which will cease to exist. It will include the Colleges at Cork and Galway and a new College in Dublin. The Belfast University will include the Belfast College, and probably at a later date Magee College, in Londonderry. The Senates of both Universities will be nominated at first, and hold office for five years. After that they will be elected academically. There are to be no religious tests, and no public money is to be paid for denominational education.

The powers of the Senate will be similar to those of other Universities. They will have the appointment and dismissal of the professors, though the first professors in the Dublin College would be appointed by a Statutory Commission, to be specially set up for each University. A dismissed professor would have a right of appeal to the Visitor, and the Visitor to the Crown, acting through a board, nominated *ad hoc* according to the nature of the dispute.

The Professors in the existing Colleges at Cork and Galway will go on. They hold their position under tenure from the Crown, and nobody proposes to interfere with them if they wish to go on. They will remain Professors of the University on the old terms. When they die or retire the Senate will appoint their successors under the provisions of the charter. It is thought desirable that the new Professors of the new College in Dublin should be appointed by a Statutory Commission which it is proposed to set up. There will be two Commissions—one for Dublin and one for Belfast—and they will have powers to sit together when joint interests arise. Otherwise they will be independent. There will be Commissions of seven members each—four elected by the Senate and three nominated by the Crown. It has been stated that the post of President of the Dublin College will be offered to Dr. D. Coffey, the Professor of Physiology in the Catholic University Medical School.

The official income of the Queen's Colleges, now standing at £56,500, will be increased to £100,000, of which Belfast will get £28,000, the new College in Dublin £32,000, and Cork and Galway £18,000 and £12,000 respectively. Belfast will also get a building grant of £60,000, and the Dublin College one of £150,000.

There is no doubt that Mr. Birrell's scheme has followed, as we foreshadowed some time ago, the line of least resistance, that is to say, the lines suggested by the Robertson Commission. We referred in our last issue to the probable effect of the establishment of new Universities on the Royal Colleges in Ireland, and we also drew attention to the disastrous consequences which would result from the paralysis of such bodies, both from the view of the medical profession and of the State. We trust, therefore, that immediate steps will be taken by these bodies to bring their position before the official promoters of the University Bill, with a view to securing some recognition or compensation for the injury which must result to them.

So far, all opinion on the Bill is based on Mr. Birrell's introductory speech, as the measure itself has not been printed for a sufficient time for its close study. One point is certain to cause active discussion, namely, the question as to whether the professors are to be appointed by the Senate or by the Crown. As Mr. Balfour pointed out, "it is only by appointment by the Crown you can be sure of not being unduly influenced by academic surroundings. . . . It is not often that the Senate would be anxious to go outside the limits of a certain number" belonging to the University. Another most important point is the question of the fees to be charged by the Colleges, as it would be a most undignified position if the various educational bodies were to engage in efforts at underselling one another. This is all the more important since underselling would be so very easy in the case of State-aided institutions. The Financial Clauses, too, will probably require amendment.

THE HEALTH OF THE NAVY.

The annual report on the Health of the Navy for the year 1906 (*a*) recently issued contains the usual statistical returns of disease in the Navy.

These returns show a continuous improvement in the general health of the Fleet, as compared with that of previous years. Not only are the case, invaliding and death ratios for the year under review lower than the average ratios for the last nine years, but the average loss of service for each person has dropped from 12.79 to 10.60 days, and this year's ratios are, under each heading, the lowest recorded since 1856.

The total force was 108,190, and the total number of cases of disease and injury was 77,842, which is in the ratio of 719.49 per 1,000, being a decrease of 119.3 per 1,000, as compared with the average ratio of the last nine years.

The average number of men sick daily was 3,144.77, giving a ratio of 29.06 per 1,000, and showing a decrease of 6.00 in comparison with the last nine years' average. The ratio per 1,000 of men sick daily on the various stations was: On the Home Station, 32.09; Channel, 21.51; Atlantic, 23.92; Mediterranean, 24.68; North America and West Indies with Particular Service Squadron, 31.04; China, 34.83; East Indies, 29.22; Australia, 28.16; Cape of Good Hope, 24.46; and Irregular List, 55.19. The Channel Fleet shows the lowest sick rate, and the Irregular List the highest, as was also the case during 1905.

The total number of persons invalided was 2,436, which is in the ratio of 22.51 per 1,000, and shows a decrease of 5.73 per 1,000 in comparison with the average of the last nine years.

The total number of deaths was 399, giving a ratio of 3.68 per 1,000, which shows a decrease of 1.46 per 1,000, in comparison with the average ratio for the last nine years. Of this number 269, a ratio of 2.48 per 1,000, were from disease, and 130, a ratio of 1.2 per 1,000, from injury.

As regards different diseases there were 2,950 cases of *influenza*, with 3 deaths. More than one-third of the cases occurred on the Home Station. There were 57 cases of *diphtheria*, with 3 deaths. There were 184 cases of *enteric fever*, with 32 deaths. The case ratio shows a decrease on the average of the previous nine years. There were 216 cases of *Mediterranean fever*, with 134 invalidings and 5 deaths. There were 54 cases of *dysentery* with 2 deaths, and 436 of *malaria* with 3 deaths. Of local diseases there were 904 cases of *diseases of the nervous system* with 13 deaths; 885 cases of *diseases of the eye;* 669 of *diseases of other organs of special sense* with 5 deaths; 675 of *diseases of the circulatory system* with 243 invalidings and 44 deaths; 8,165 of *respiratory diseases* with 134 invalidings and 31 deaths; 11,556 of *diseases of the digestive system* with 287 invalidings and 19 deaths; 600 of *lymphatic and glandular diseases* with 2 deaths; 767 of *diseases of the genito-urinary system* with 81 invalidings and 12 deaths; 671 of *diseases of the organs of locomotion,* 10,950 of *diseases of the connective tissue and skin,* 16,672 of *wounds and injuries* with 168 invalidings and 121 deaths. Nine persons committed suicide.

Of *tubercle* 290 cases with 216 invalidings and 39 deaths are recorded. Both as compared with last year and with the last nine years, the case and invaliding ratios show a satisfactory decrease, while the death ratio is identical with that of last year, but shows a decrease on the nine years' ratio. For the first time in these reports the cases of tubercular disease have been classified, with the following results:—Of the total number of cases, pulmonary tubercle contributed 256 cases, with 35 deaths; tubercle of glands, 8 cases; tubercle of testis, 7 cases; tubercular disease of joints and bones, 6 each; tubercular meningitis, 3, all fatal; acute miliary tubercle, 1 fatal case; tubercle of larynx, tubercular ulceration of rectum, and tubercular lupus, 1 case each.

Of *venereal diseases* the total number of cases recorded is 13,193, viz., *chancroid,* 1,672; *syphilis primary,* 1,888; *syphilis secondary,* 3,153; and *gonorrhœa and its sequelæ,* 6,480 cases. Chancroid gives 13 invalidings; syphilis primary, 10 invalidings; syphilis secondary, 163 invalidings and 4 deaths; gonorrhœa and its sequelæ, 93 invalidings and 2 deaths—a total of 279 invalidings and 6 deaths. The total number of days' loss of service was 316,631, while the average daily number ineffective from these diseases was 867.46.

The enormous amount of sickness from these diseases shows very little sign of any diminution as years go on. A slight fluctuation is noticed year by year, but the case ratio for the year under notice is practically identical with the average ratio of the last nine years. Nearly all other diseases show a pretty steady yearly decrease; these remain *in statu quo.* Australia shows the highest case ratio. The case ratio on that station was 214.75 per 1,000—an increase of 58,57 as compared with last year, and of 56.73 in comparison with the average ratio for the last nine years. At the same time it is worthy of note that Brisbane, where apparently a modified Contagious Disease Act is in force, is noted as being practically free from these diseases; and the medical officer of the *Pegasus* reported that at Noumea, where the French authorities rigidly enforce a Contagious Disease Act, not a single case was contracted, although leave was freely given to the crew during all days of the visit of the ship to this port.

The Appendix contains an interesting and careful report on Caisson Disease by Staff-Surgeon Rees, who recently acted as secretary to a committee appointed by the Admiralty to inquire into the subject. He suggests that safety in decompression may be secured by attention to two points—limiting the time of exposure and bringing the diver up slowly.

Royal Army Medical Corps.

Capt. J. H. R. Winder, M.D., B.Ch., from Malta, has been appointed to the Irish Command at Belfast for duty. Capt. D. Harvey, M.B., has been directed to proceed to Naini Tal for duty in the Station Hospital during the summer months. Sergt.-Major Harwood, the warrant-officer at the Connaught Hospital, left Aldershot on Saturday for service at Bermuda. Capt. E. Brodribb, M.R.C.S., from the Royal Army Medical College, has been appointed to Shorncliffe, as specialist in ophthalmology.

Diseases following Earthquake in Jamaica.

The Medical Officer of Kingston, Jamaica, in his report on the health conditions in the city during the last year, traces many cases of chest and pulmonary troubles, stomach and liver complaints to the exposure and privation following the earthquake. He thinks the septic dust from the broken buildings blown about by strong winds through months of drought spread disease.

REVIEWS OF BOOKS.

THE QUARTERLY JOURNAL OF MEDICINE. VOL. I. (*a*)

In this are several papers of great interest, among which we may mention one on "The Parathyroid Glands" (their function and relation to the thyroid gland). The author's object is to prove that the glands are portions of the main thyroid gland which have assumed functional activity, but have not yet formed vesicles. He brings forward evidence from (1) an evolutionary standpoint; (2) the comparative histology of the thyroid gland; (3) the comparative histology of the parathyroid glands; and (4) the embryonic and cystic adenomata of the thyroid gland. In the first place, the importance of the function of an organ depends on the duration of its existence, the vital functions being earliest developed. The long-established viscera will not be so subject to anatomical variations as those of recent origin. If the parathyroids possess the supreme importance attributed to them, their philogenetic age would be great, and their anatomical features should be constant as other ancient organs. Yet, more than any active organ in the body, parathyroids are liable to wide variation.

The author points out the very varied results obtained by different experiments after removal of the parathyroids, and explains this by the difficulty of performing the operation without injuring the thyroid gland and the likelihood of leaving some parathyroid tissue behind. He also quotes the definite statement of some experimenters that the more severely the thyroid is damaged the more likely is a fatal result to ensue.

The views of the author are founded on an examination, naked eye and minute, of the glands in the neck in 58 human subjects and 77 animals and birds. The following are his conclusions:—

(1) The parathyroids are not merely embryonic in nature. In the majority of specimens there are definite signs of cellular activity.

(2) They are portions of the main thyroid gland which have assumed functional activity, but have not yet formed vesicles.

(3) Parathyroids may develop into thyroid tissue, and intermediate types occur.

(4) The secretion of the parathyroids is a colloid material indistinguishable from thyroid colloid.

(5) The parathyroids, therefore, are glands essentially thyroidal in nature, possessing no peculiar functions, but engaged in the active secretion of the same substance as the thyroid gland.

This paper is accompanied by a very full bibliography of the subject, and is well illustrated.

In a paper on "Cervical Ribs, and their Relation to Atrophy of the Intrinsic Muscles of the Hand," the author refers to several cases he has seen since 1893 in which there was a wasting of the intrinsic muscles of the hand, which did not go on to progressive muscular atrophy, and where the wasting was not confined to the muscles supplied by a single nerve. A paper by Dr. William Thorburn in 1904 suggested that these cases were due to the pressure of a cervical rib on the first dorsal nerve, and on taking skiagrams of as many of these cases as could be traecd, 10 out of 14 showed well-marked cervical ribs.

Another paper of peculiar interest is one on "An Undescribed Form of Dwarfism Associated with a Spatulate Condition of the Hands." The authors describe 4 cases which they have seen; three of these were sisters, and the fourth case was also a female. The dwarfing and broadening of the hands gives the cases some resemblance to achondroplasia. That they are not cases of this affection, however, is shown by the following facts:—(1) The proximal segments in each limb are not relatively shorter than the distal. The hands when hanging by the side reach to about the normal position on the thighs. (2) The broadness of the hands extends to the terminal phalanges of the fingers, and not only to the proximal, so that the fingers are not conical, as in achondroplasia, and when the hand is held with the proximal phalanges closely approximated, the two distal phalanges are also closely approximated, so that there is no tendency to the appearance described by Marie as *la main-en-trident*. The last paper is one on "Ochronosis,". with a description of a case. The whole journal is well got up, and the illustrations, some of which are in colours, are beautifully reproduced.

THE EDINBURGH MEDICAL JOURNAL. (*a*)

This volume contains a number of useful and interesting papers, dealing with various branches of clinical work. Dr. W. J. Stuart gives an elaborate *résumé* of our knowledge concerning "Operative Injuries of the Thoracic Duct in the Neck"; Alexis Thomson discusses "The Making of a Shelf below the unduly Mobile Kidney"; and Miles reviews the recent literature on "The Surgery of the Prostate and on the Ulterior Results of Operations for Mammary Cancer." On the pathological side much interest attaches to the blood examinations made on a patient subsequent to excision of a ruptured spleen, by Matthew and Miles, and also to Monsarrat's paper on "Renal Sarcoma in Children." Clinical medical work is represented by Philips' paper on "Certain Adaptations of Percussion in the Diagnosis and Prognosis of Respiratory Disease," and by Sutherland's paper on "Pulmonary Hypertrophic Osteoarthropathy." Papers of interest to toxicologists, and to specialists in eye and ear work, and in diseases of women, are also included, and help to make the volume one of interest to all sections of the profession.

STEPHENSON ON OPHTHALMIA NEONATORUM. (*b*)

This very interesting monograph received the Middlemore Prize of the British Medical Association, and certainly, even if its value is only based on the amount of labour bestowed upon it by Dr. Stevenson, it well deserved recognition. The book begins with an account of the effect of ophthalmia on infants in the past, and is based on the statistics of numerous lying-in hospitals, London and provincial Poor-law maternities, foundling hospitals, and eye hospitals and clinics. We learn that, whereas the percentage of cases of ophthalmia in 15 Continental maternities prior to 1882 was 4.05, the percentage in six British maternities after that date was only 0.22.

The next section deals with the origin of ophthalmia, and in this the author refers to the many various theories which have held the field since Quellmalz in 1750 first insisted upon its connection with maternal leucorrhœa. The ultimate result of the author's inquiries is to determine the existence of two forms of ophthalmia neonatorum—a severe form which is always gonorrhœal in origin, and a milder form the outcome of the action of other organisms, traumata, and certain constitutional states such as syphilis.

The next section deals with the symptoms and histology of ophthalmia, and the two next sections with its diagnosis, prognosis and prevention. The section dealing with prevention is long and important, and its conclusion may be said to be that either a 1 per cent. solution of silver nitrate, or a 1 in 4,000 solution of corrosive sublimate, should be dropped into the eyes of every baby born in a public institution.

The last section of Dr. Stevenson's work deals with the treatment of ophthalmia, and we are glad to see that here he recommends some of the newer silver salts such as argyrol and protargol as a substitute for the nitrate of silver. A 25 per cent. solution of argyrol is what he personally uses.

Dr. Stevenson has bestowed an immense amount of time and thought on his monograph, and we are very glad to be able to heartily congratulate him on the result of his labours. Obstetrical specialists do not

require to be told of the truth of his conclusions, but there is still, we fear, a large body of medical men who are inclined to regard the precaution he recommends as unnecessary. We trust, however, that the figures in the book before us will go a long way to convert such doubters.

A SYSTEM OF MEDICINE. (*a*)

THE third volume of Allbutt and Rolleston's "System of Medicine" is divided into three parts. The first deals with general diseases of obscure origin; the second with the diseases of the alimentary canal; and the third with the diseases of the peritoneum. The volume has undergone very considerable rearrangement, and "in the main, especially as regards the more important articles, is a rewritten, rather than a revised, successor of Volume III. of the original edition." Amongst the many new articles may be mentioned Dr. Garrod's articles on rheumatoid arthritis, osteo-arthritis, and other forms of joint affections; Dr. Batty Shaw's article on pulmonary osteo-arthropathy; on achondroplasia by Dr. Poynton; on congenial hypertrophy of the pylorus by Professor Still; on the bacteriology of diarrhœa by Dr. Slater; on acute peritonitis by Drs. Allchin and Andrewes; and on sub-phrenic and other forms of peritoneal abscess by Dr. Acland.

In addition to these new articles, several others have been almost entirely rewritten. The more important of these are the articles on diseases of the mouth by Mr. Walter Spencer; on appendicitis, intestinal obstruction, and visceroptosis by Mr. Lockwood, Mr. Barnard, and Dr. A. Keith, respectively; and on the differential diagnosis of diseases of the anus and rectum by Mr. Mummery.

The third volume more than maintains the reputation of its predecessors, and from a literary point of view is in most respects admirable. It seems, however, a pity that in a book of this kind, on which so much labour has been spent, there should not be a freer use of illustrations.

HOLT ON THE DISEASES OF CHILDREN. (*b*)

IT is not often that we receive for review in the same month two works coming from the same country, both of which may be regarded as at the very top of their class. Yet recently we received for review Prof. Whitridge Williams' work on "Obstetrics," and now we have received Prof. Holt's work on "The Diseases of Children." The latter work, with which we are at present alone concerned, has reached its fourth edition, and has been thoroughly revised. It has also been somewhat enlarged. The principal alterations have been made in the sections of the book dealing with nutrition. These parts have been largely rewritten, and a considerable amount of new matter introduced. The remainder of the book has only been slightly altered.

The section devoted to nutrition consists of six chapters. The first is introductory, and deals with food constituents, and the purposes they serve in nutrition. Chapter II. deals with the dietary of the infant, and discusses in detail the various forms of foods, natural and artificial. There is some interesting information on the subject of proprietary foods, which, as the author points out, though not by any means perfect substitutes for breast milk, are often of considerable value for temporary use in pathological conditions. Chapter III. deals with the different methods of infant feeding—maternal breast, wet nurse, mixed feeding, artificial feeding, etc. It contains some most valuable tables dealing with percentage feeding, etc. Chapter IV. deals with feeding after the first year, and is also most interesting. Chapters V. and VI. deal respectively with the derangements of nutrition and diseases due to faulty feeding.

As we have already said, we consider Prof. Holt's work to be the standard work on the diseases of infancy and childhood, and we heartily congratulate the author on the fact that it has reached its fourth edition.

NEWMAN ON MOVABLE KIDNEY. (*a*)

THIS book contains a systematic consideration of the displacements and malformations of the kidney, and is based on the author's practical experience. The first chapter deals with the classification of the displacements and malformations of the kidney, and its normal anatomy. The second, third and fourth chapters deal with "movable kidney." The sixth chapter deals with floating kidney, and the seventh with fixed malpositions and malformations.

We look with interest to see what the author considers are the indications for and contra-indications to nephrorraphy in cases of movable kidney. He considers the operation should be recommended in all uncomplicated cases in which the pain is distinctly renal, where there is evidence that the displacement causes twisting of the pedicle of the kidney, and where gastro-intestinal symptoms are pronounced when the patient is active, but are relieved when she is at rest. On the other hand, he considers that the operation should not be performed when the symptoms distinctly referable to the mobility of the kidney are a small part of the trouble.

Dr. Newman's contribution to the literature of renal displacements will prove of interest and assistance both to surgeons and to physicians.

Tropical Disease Research.

A REPORT of the Advisory Committee for the Tropical Diseases Research Fund has just been issued. The revenue for last year was made up by contributions from the Imperial Government (£500), the Government of India (£500), from funds at the disposal of the Rhodes Trustees (£200), and £1,875 from the Colonial Governments. The whole made a total of £3,075. The expenditure was a grant to the Liverpool School of Tropical Medicine of £500, to the London School £1,083, to the University of London £750, and to Cambridge University £100. The total was £2,433. The Liverpool grant was employed for the payment of a lecturer in economic entomology and parasitology. A further grant has been applied for and the Advisory Committee have agreed to allot £500 extra to the School from April 1st, the amount to be applied definitely to work in connection with sleeping sickness. A programme of that work is to be submitted before the grant is made. The London School has made application for a further sum, and the Committee have decided on an extra grant of £1,000 for the establishment of a post of entomology. The Committee have also been approached by the Secretary of State for advice as to the existing conditions of sleeping sickness in Uganda. The Committee decided to advise that the measures to be adopted should include:—(1) The segregation of all persons known to be infected with trypanosomes in camps which should be situated in places free from glossina; (2) the removal of the apparently healthy from fly-infested areas to places where it is believed that no fly exists; and (3) the clearing of such bush as would afford shelter for the fly at all fords, ferries, landing places, and sources of water supplies, for a limited area, such cleared areas to be kept free of bush and cultivated with low-growing crops which could not afford suitable shelter for the fly. These recommendations have been approved by Lord Elgin, and steps are now being taken to carry them into effect.

(*a*) "A System of Medicine by Many Writers." Edited by Thomas Clifford Allbutt, M.A., M.D.Cantab., LL.D., D.Sc., F.R.C.P.Lond., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, etc.; and Humphry Davy Rolleston, M.A., M.D.Cantab., F.R.C.P.Lond., Physician to St. George's Hospital, etc. Vol. III. Pp. 1,040. London: Macmillan and Co., Ltd. 1907. Price 25s. net.

(*b*) "The Diseases of Infancy and Childhood." By L. Emmett Holt, M.D., Sc.D., Professor of Diseases of Children in the College of Physicians and Surgeons (Columbia University) New York, &c., &c. Pp. xvii and 1170, with 241 illustrations and eight coloured plates. Fourth edition, revised and enlarged. London: Sidney Appleton. 1907.

(*a*) "Movable Kidney and other Displacements and Malformations." By David Newman, M.D., Surgeon to the Glasgow Royal Infirmary, &c., &c. Pp. xii. and 233. Illustrated. London: Longmans, Green and Co. 1907.

Weekly Summary of Medical Literature, English and Foreign.

Specially compiled for The Medical Press and Circular.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Report of a Case of Degenerated Uterine Myoma.—Vander Veer (*Surgery, Gynæcology and Obstetrics*, March, 1908).—Under this heading is cited the history of a patient, æt. 53, married, two children alive, one 29 years, the other 22 years; a four months' miscarriage fourteen years previously. The patient was admitted to hospital suffering from a large abdominal tumour, which she had noticed first four years previously. The menopause was past three years. The bowels were very constipated. On examination the tumour was proved to be twice the size of a four-month pregnancy. Fluctuation was elicited. On opening the abdomen a thick-walled, non-adherent cyst presented; 18lb of fluid was evacuated, one cyst not being opened. It was then found that the tumour consisted of a myoma of the uterus. Sub-total hysterectomy was performed. The specimen proved to be multiple myoma of the uterus. Cyst of the uterus, resulting from degeneration of a large myoma. Compression and obliteration of the uterine cavity, with degeneration and destruction of the mucosa. The cavities were lined with a smooth, shining membrane, a portion of the large cavity was thrown into folds and distributed through it were yellow areas containing cholesterin crystals. H.

Stab Wound of Fœtus in Utero.—Steele (*Surgery, Gynæcology and Obstetrics*, March, 1908).—The history of the case is as follows:—On September 15th, 1907, Mrs. M., æt. 19 years, married 3 years, mother of a child 22 months old, stabbed herself with a knife in the right side of the abdomen in a fit of anger. The site of the wound being four inches to the right and one and a half inches below the umbilicus. At the time she was pregnant six and a half months. Patient was brought to hospital and the wound treated, being quite healed at the end of a week. On November 28th, 1907, she delivered herself of a live male child, normally developed and at term. It was observed, however, that in the lateral aspect of the abdominal wall, on the left side, one and a half inches above the anterior superior spine, was a wound through which intestines protruded. The intestines were wrapped in antiseptic gauze and the child brought to hospital. On examination a partly healed incised wound an inch long at the point indicated was demonstrated. The jejunum and ileum adherent to its margins protruded. The upper part of jejunum was enormously dilated. The lower part, all the ileum and colon were coiled up and adherent, and very narrowed in calibre. Meconium was found in the rectum. The abdomen was opened, but the contractions and adhesions made any operation impossible. The child lived eight hours. On post-mortem examination it was found that the jejunum was completely cut across by the stab wound at about six inches below its juncture with the duodenum. The points of interest are: how the child survived the wound and went on living and growing. Another interesting fact was the complete occlusion of the two divided ends of intestine of the fœtus, and the presence of nearly 3 oz. of glairy fluid in the stomach at the time of operation—ten hours after the birth. Literature upon subject reviewed. H.

The Diagnosis of Early Pregnancy.—McDonald (*Amer. Journ. of Obst.*, March, 1908).—In this paper the author enumerates the ordinary early signs on vaginal examination of pregnancy, and then describes other signs which are seldom—and some never—mentioned in text-books. The first is asymmetrical enlargement of the uterus, which may almost become a distortion, and may give rise to errors of diagnosis. It is sometimes likened to a face swollen from an inflamed tooth, and gives a different sensation to the hand than the part which is not hypertrophied. On palpation it seems as if a tumour is annexed to the uterus, and it has been diagnosed as a tubal pregnancy. It has been thought by Dickinson and others that the harder, firmer side represents the side of gestation, while Hubl, Schauta, and Landau believe that the softer side is the location of the pregnancy. The next sign is flexibility of the isthmus of the uterus, which depends upon the softening and vascularity of the uterine tissue connecting the cervix and corpus uteri. Other signs are the "jug" sign, in which the body of the uterus is likened to the bulging part of a jug, while the cervix is the spout. This sign depends upon enlargement of the uterus, so that it may cause a notable protuberance or bellying. It does not occur until the third or fourth month, so is not of great value in the early weeks, when the enlargement is slight and often asymmetrical. Ladinski has recently drawn attention to a spot upon the anterior wall in the median line just above the junction of the cervix, where a marked change in consistency is said always to occur. This spot is said to be elastic and fluctuating in character. The signs of compressibility (Hegars) and flexibility of the isthmus, taken with intermittent contraction and uterine enlargement and softening, allow of a positive diagnosis in the early weeks of pregnancy. F.

Recent Advances in Obstetrics: "Better Procedure."—Cragin (*Amer. Journ. of Obst.*, March, 1908).—As compared with the past, our better procedure to-day is based largely upon a better knowledge of obstetric pathology and the mechanical problem of delivery. Realising, as we now do, the seriousness of the lesion in pernicious vomiting of pregnancy, and how important a *rôle* is played by disturbed metabolism, we are no longer satisfied with the ordinary examination of the urine for albumin, casts and urea, but have it examined by a chemist, the nitrogen partition determined, and the presence or absence of acetone, diacetic or oxybutyric acid, indican and bile pigment ascertained. There is no one of the laboratory findings nor groups of findings which can be relied on exclusively for prognosis or indication for treatment. It is only when they are studied in connection with the clinical picture of the patient that our decision should be made. As to the treatment of pernicious vomiting of pregnancy, the writer believes that the best results are obtained by colon irrigations, rectal feeding for a short time only, and early emptying of the uterus. Recent knowledge of chorio-epithelioma demonstrates well the fact that prolonged menorrhagia or metrorrhagia following labour, abortion, or operation for hydatid mole should be looked on with suspicion, and that early diagnosis and hysterectomy alone give hope of satisfactory results. In the treatment of puerperal infection, our knowledge of the ease of spreading the infection has brought about one improvement in procedure—viz., the rule to keep out of the uterus unless it contains materials which should be removed, and if the removal of infected material is needed, to do this with the least possible injury to the uterine wall so as to avoid opening new avenues of infection. Frequent and careful observations on the size of the child's head as compared with that of the pelvic canal, especially in cases which have had a previous difficult labour, will often tell us the time beyond which pregnancy should not continue, and induction of labour two weeks before term will often secure a relatively easy and safe birth for a child which otherwise would be lost. F.

Arrest of Hæmorrhage after Labour.—Brock (*Practitioner*, January, 1908).—The clinical features of a post-partum flooding leave no doubt in the writer's mind that the bleeding is venous. The blood from the huge maternal sinuses is carried to the inferior cava by large veins, which are valueless. Unless the mouths of the sinuses are securely folded together, regurgitation must result. The treatment of mild cases of P.P.H. is thoroughly agreed upon. That of serious P.P.H. resolves itself into the treatment of regurgitant venous hæmorrhage, the extreme gravity of which depends on the fact that the blood which is pouring into the uterus is regurgitating from the inferior vena cava through valveless veins. Its correct treatment, therefore, must be carried out by one of two methods (1) Either by applying direct pressure to the bleeding sinuses, or (2) by elevating the pelvis and compressing, not the aorta, but the inferior vena cava by precisely the same manœuvre, and thus stopping the backwash of blood from the latter. F.

MEDICAL NEWS IN BRIEF

Schools for Mothers.

"A SCHOOL FOR MOTHERS" was started recently in St. Pancras, London, as an interesting experiment in the education of poor mothers in the feeding and training of their children. The Manchester Ladies' Public Health Society held a meeting at the Town Hall on April 1st to hear about the scheme from the Hon. Mrs. Bertrand Russell.

The Lady Mayoress (Mrs. Edward Holt) presided, and said that after visiting the new school she was fully satisfied that it was in a position to do much good work.

Mrs. Redford, the President of the Society, said that most of the things that were being done in the London school had been more or less undertaken by the workers of the Society in the poor quarters of Manchester.

Mrs. Eckhart mentioned that during last year the Manchester lady health visitors paid more than 20,000 visits to homes where there were babies. The instruction given at these visits was of incalculable value.

The Hon. Mrs. Russell gave an interesting description of the school, which is placed in a cheap shopping street near St. Pancras Station. It had already, she said, done something to lessen infant mortality. Of every 1,000 babies born, she said, about one-fifth died, and in many places the proportion was higher. The infant mortality was now probably as high as it was 60 or 70 years ago, and it was clear that something drastic must be done to bring the infant mortality into line with the improvement in general health. The school had a big shop window, filled with pictures of rickety babies, and it displayed an invitation to passing mothers to come in and learn how to keep their babies from becoming bow-legged. A cookery teacher from the London County Council came down to give demonstrations in cheap cooking—"How to prepare Irish stew for fivepence," and so on. It was an important part of the scheme to get the father interested in the welfare of the mother and child. Fathers were invited to come to the school, and after a cup of coffee and a pipe they received "talks" on hygiene. They had not yet solved the question of the older girls, "the apprentice mothers," but they hoped to develop a system of education for these on lines already successfully followed on the Continent. It would be necessary ultimately to open a milk depôt for the use of mothers who could not feed their babies themselves. Prizes were given to the mothers who attended regularly and who followed the advice given. The mothers paid a penny a fortnight each for the weighing and for the classes. The school was now treating about 100 babies a year, and was preparing the mothers for the care of many hundreds of other children. It was estimated to cost about £300 a year. A school on the same lines had been recently opened in Birmingham. The school was helping to impress on the mothers the importance of hygiene and the sacredness of child life. Mrs. Russell denied that they were pauperising the women.

The new school was warmly commended by Dr. Helme.

Dr. J. M. Rhodes said that in his opinion the slum owners were largely responsible for the horrible "slaughter of the innocents" which went on year by year.

Dr. Niven moved a resolution in favour of forming a school for mothers in Manchester, and requesting the Ladies' Public Health Society to form a committee to inaugurate a scheme, with the co-operation of persons interested in the subject of infant mortality.

Dr. Hutton seconded the resolution, and it was carried.

Germicides and Disinfectants.

DR. SAMUEL RIDEAL gave, on April 2nd, at the London School of Tropical Medicine, a demonstration of the Rideal-Walker test for determining the efficiency of disinfectants. The test was invented by Dr. Rideal in collaboration with Mr. Ainslie Walker in order to determine the relative values of germicides. Dr. Rideal used for the purposes of demonstration bacillus typhosus, and the test consisted in exposing one portion of a growth of the typhoid germ to the action of a standard strength of carbolic acid, and another to that of the particular disinfectant to be tested, and in determining the extent to which the germ has been destroyed in each in the same length of time. The test has been adopted by the War Office, the Admiralty, and other Government departments, as well as by municipal and other public authorities in Great Britain and the Colonies. Professor Hewlett, in the course of a discussion which followed, said he would like to emphasise that the public were constantly being defrauded by having foisted upon them various so-called disinfectants which had frequently no germicidal action whatever. Not only were the public defrauded in this way, but there was also very grave danger introduced when a person believed he was using something which would actually destroy germs and was thereby lulled into a sense of security when in reality no sense of security was justified. There was a growing need for some limitation of various articles which were put on the market as disinfectants when they were not efficient as such. Nothing in the way of disinfectants should be foisted upon the public which had not been proved to be germicidal in their action.

Small-pox Outbreak near Grantham.

A SPECIAL meeting of the Grantham Rural District Council was held at the Guildhall on April 1st.

Dr. C. H. D. Robbs, the medical officer, said it appeared there were four cases of small-pox at Woolsthorpe-by-Belvoir, and they were clearly traceable to a man who came back to England about three weeks ago on a training ship, landing at Southampton. He was ill when he landed, and went to Woolsthorpe, and he was not seen by a medical man until Sunday last. He walked about the village suffering from modified small-pox, and as a result of that three other people came into contact with him and had caught the disease, two of the cases being very serious. The nursing available was very limited indeed, and it was almost impossible with the present means at their disposal to even approach the question of the isolation of patients. In reply to questions put by members of the Council, Dr. Robbs said the four cases were in three houses. The epidemic had got a fortnight's start of them, and vaccination was not in a very good state. In one house affected there were three small children.

The Clerk mentioned that there were cases in various ships at Southampton, and he had received notice that other soldiers had been on those vessels. One had came into Manners Street, Little Gonerby, and another man who had not yet arrived was going to Belvoir. He was now at Woolwich. He did not know what boat the affected man had come on.

The Council decided to take two empty houses in the immediate neighbourhood which are in a isolated position, furnish them, and then quarantine not only the patients, but as far as possible the contact cases.

The Chairman thought it was desirable that they should find out why the authorities let those people go as they did.

Mr. Ernest Harnack.

THE case of Dr. Hall Edwards, of Birmingham, has caused the public to notice the equally distressing case of Mr. Ernest Harnack, of the London Hospital. Mr. Harnack has been a sufferer for ten years, and has recently undergone an operation—the third serious one within the last six months. As head of the X-ray department of the hospital, Mr. Harnack has carried out frequent experiments, and some of his discoveries have proved of much value. "After I had been engaged in the work about three or four years," said Mr. Harnack to an interviewer, "I began to feel a tingling of the fingers. I thought at first that it was caused by developing the plates, but the true explanation soon became apparent. Since that time I have suffered great agony. In 1900 a finger-nail was removed. Then in course of time I lost all my nails. Last October I was operated upon for a growth on the back of the left hand. At Christmas I found that the growth was recurring, and in the middle of January I underwent another operation. The third finger was amputated; also, it being feared that the growth was of a malignant character, all the glands of the left arm were removed. At the same time the right hand was operated upon, for it was covered with ulcers. The hand was scraped, and skin from the left arm was grafted upon it. Altogether I was on the operating table two and a half hours. Unfortunately, the skin grafted on to the right hand gave way, and a few days ago three fingers were removed—I have now only the little finger and thumb, so that the hand is practically useless." Mr. Harnack is only 40.

The Notification of Consumption Cases in Edinburgh.

THE Edinburgh Medical Officer of Health reported to a meeting of the Health Committee of the Town Council on March 31st that during the year in which the order had been in force 804 notifications had been received. The monthly returns since March of last year showed the following results:—March, 140; April, 7; May, 51; June, 55; July, 61; August, 51; September, 44; October, 63; November, 69; December, 41; (1908) January, 66; February, 88. It was also stated that in consequence of this disease having been admitted to the list of notifiable diseases, the work of the Medical Officer's department had greatly increased, as 513 dwelling-houses, representing 667 apartments, had been visited and disinfected, while the separate articles dealt with numbered 7,836. The total cost of notification was £64 7s. 6d.

Health of Irish Towns.

THE deaths registered in the Dublin area for the week ending 21st ult. represented an annual mortality of 25.5 per 1,000 of the population. There were 8 deaths from influenza. The rate in Dublin is exceeded by that of only four European cities in the list of the Registrar-General of Ireland: St. Petersburg 32.1, Warsaw 29.1, Trieste 31.1, Venice 28.3. The following towns in Ireland presented for the four weeks ending 21st ult. rates of 20 or over: Armagh 22.3, Belfast 26.4, Clonmel 21.8, Cork 27.9, Drogheda 20.4, Galway 24.3, Kilkenny 22.1, Limerick 28.3, Lisburn 23.9, Londonderry 20.7, Lurgan 25.4, Portsdown 24.6, Sligo 27.6, Tralee 48.9, Waterford 29.7, Wexford 25.7. The lowest rate is that of Dundalk, 16.

PASS LISTS.

University of Durham Faculty of Medicine.

The following candidates passed the Second Examination for the Degree of Bachelor in Medicine during March, 1908:—Anatomy, Physiology, and Materia Medica.—Pass List.—William George Bendle, Eliot Watson Blake, Francis Percy Evers, Ivor Stanley Gabe, Cyril Gray, Howard Tomlin Hunter, George Eric Warner Lacey, Thomas Alfred Peel, Elliot Jessie Ramsbotham, Harold Frieze Stephens, Alfred Tulloch Thompson, Charles Sim Thompson.

The following candidates have passed the First Examination for the Degree of Bachelor in Medicine, March, 1908:—I.—Elementary Anatomy and Biology, Chemistry and Physics.—Harold Fairclough (Honours, Second Class). Pass List.—Eric Lawrence Hancock, James K. Johnston Haworth, John R. D. Holtby, L.R.C.P. and S.Glas.; Edwin Kidd, Colin Mearns, Fred. Phillips, B.A., Alex. Gordon Taylor. II.—Elementary Anatomy and Biology.—Fife Appleton, Ronald G. Badenoch, William L. Clements, Arthur T. Crilley, Norman Hodgson, James Kerr, Francis J. Lidderdale, Sydney E. Murray, Andrew G. McFarlane, John George Ogle, Charles H. Robson, Sidney Scott, William A. Slater, Thomas C. Storey, Samuel K. Young. III.—Chemistry and Physics.—Robert Ernest Bell, Arthur S. Hopgood, Russell V. Steele. IV.—Elementary Anatomy.—Sam Phillips Bedson, B.Sc., Theonie Renée Burrell. V.—Elementary Anatomy, Chemistry and Physics.—William Guy Lidderdale.

Trinity College, Dublin.

THE following candidates have passed the Intermediate Medical Examination, Part II.:—Adrian Stokes, Charles M. Finny, David L. M'Cullough, passed on high marks; Marius A. Diemont, Beatrice Hamilton, John H. Woodroffe, Peter H. Lemass, Herbert de L. Crawford, Robert Dixon, Douglas M. Moffatt, Roelof A. Albertyn, Euphon M. Maxwell, Edmond F. Lawson (Sch.), Perceval G. Leeman, Thomas M. Crawford, Hilgard Müller, William P. H. Smiley, Vicars M. Fisher, John G. Ronaldson, Arnold K. Henry, John B. Burgess, George F. C. Healy, John G. Dods, Samuel V. Richardson, Arthur C. Hallowes, Victor B. Best, Richard H. Mathews, Charles H. Denham, Brindley H. Moore. Previous Dental Examination (Materia Medica): George Elliott. Anatomy and Institutes of Medicine: Arthur A. Smith. Physics and Chemistry: Maurice Horan.

Royal College of Surgeons in Ireland.

PRIZE list, winter session, 1907-1908:—Descriptive Anatomy—Junior: J. Prendiville, first prize (£2) and medal; A. G. Mosbery, second prize (£1) and certificate. Senior: J. T. Duncan, first prize (£2) and medal; P. J. Wigoder, second prize (£1) and certificate. Practical Anatomy—First year: V. J. White, first prize (£2) and medal; I. M. Swanepoel, second prize (£1) and certificate. Second year: T. M. Thomson, first prize (£2) and medal; F. W. Warren, second prize (£1) and certificate. Practice of Medicine—R. Adams, first prize (£2) and medal; J. Menton and Miss C. F. Williamson (equal), second prize (£1) and certificate. Surgery—R. Adams, first prize (£2) and medal; G. C. Sneyd, second prize (£1) and certificate. Midwifery—J. Menton, first prize (£2) and medal; Miss I. M. Clarke and Miss C. F. Williamson (equal), second prize (£1) and certificate. Physiology—J. T. Duncan, first prize (£2) and medal; F. W. Warren, second prize (£1) and certificate. Chemistry—T. P. Roberts, first prize (£2) and medal; M. J. Hillery, second prize (£1) and certificate. Pathology—J. S. Pegum, first prize (£2) and medal; H. R. Tighe, second prize (£1) and certificate. Physics—M. J. Hillery, first prize (£2) and medal; T. D. Condell, second prize (£1) and certificate. The following lectures and practical courses of the summer session commenced April 1st—Biology, Practical Chemistry, Histology, Materia Medica, Operative Surgery, Public Health and Forensic Medicine, and Dissections.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

THE following candidates have passed the preliminary examination, March, 1908.—B. Glasson (with honours), A. J. Almeida, D. W. Beamish, T. K. Beattie, A. E. Brandon, P. D. Daly, H. S. Digges, R. Edgar, J. J. Elliott, H. C. Hatch, Miss G. McHugh, J. H. Madden, A. Morris, M. J. Mullen, C. Murray, A. F. I. Patterson, G. E. Pepper, R. Slaney, T. S. Smith, F. R. Swanton.

THE results of the inoculative tests made in connection with the suspected cases of rabies at Northampton were negative, and the Muzzling Order was revoked on the 31st ult. by an Order which came into operation on April 4th.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.**

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

Dr. Jervois Aaron's paper on "Dysparcunia in the Male" is marked for early insertion.

Dr. S. J. Ross is thanked for his communication, proof of which will be sent him in due course.

Mr. H. M. L.—The subject is one which only remotely affects the medical profession. It is moreover fraught with legal technicalities and dangerous to handle. We do not therefore feel justified in taking the matter up in our columns.

THE CIGAR HYGIENIC

If a Harley Street specialist is right in declaring that the better the cigar the more harmful it is, it must be extreme solicitude for our health that leads a man we know to advise our selection from his cigar-case.—*London Opinion.*

Mr. W. H. W.—Your communication reached us as we were "at press," too late for present issue.

Anti-Quack.—The business would seem to be conducted by the father and daughter, who constitute the so-called "Limited Liability Company." We are making inquiries.

Flumen.—In the annual report of the Port of London sanitary authority it is announced that in the Thames training ships there were 130 cases of sickness during 1907, the most serious being seven of scarlet fever on board the "Arethusa," and eighteen of enteric fever on board the "Cornwall." The Medical Officer states that there was a previous epidemic of enteric on the "Cornwall" in 1903. The cases numbered sixteen, and the outbreak was attributed to blankets, purchased as second-hand, which had been used in South African concentration camps. In the present instance, although the source of infection has not been definitely traced, suspicion, says the report, points to bedding being again responsible.

Meetings of the Societies, Lectures, &c.

Wednesday, April 8th.

Hunterian Society (London Institution, Finsbury).—8.30 p.m.: Annual Discussion on Rheumatism (opened by Dr. F. Taylor). Dr. Poynton and Dr. Horder will speak on the Bacteriological Aspects of Rheumatism and Mr. Luff on the Irregular Manifestations of Rheumatism and their Treatment.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. J. Cantlie: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. C. O. Hawthorne: The Clinical Anatomy and Physiology of the Nervous System.

Thursday, April 9th.

Royal Society of Medicine (Obstetrical and Gynæcological Section) (20, Hanover Square, W.).—7.45 p.m.: Specimens will be shown by Dr. Herbert Spencer and Mr. Alban Doran. Short Communications by Dr. Macnaughton-Jones, Dr. Kedarnath Das, and Dr. Nepean Longridge. Paper by Dr. Herbert Williamson and Dr. Eardley Holland: A Case of Intra-Uterine Death of the Fœtus occurring in Six Consecutive Pregnancies, with Observations upon the Importance of the Examination of the Fœtal Tissues for the Presence of the Spirochaeta Pallida.

Harveian Society of London (Stafford Rooms).—8.30 p.m.: Mr. L. B. Rawling: The Surgical Treatment of the Incompletely Descended Testis. Clinical Cases will also be shown.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. G. Oliver (Harrogate): Recent Studies in Arterio-sclerosis.

North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynæcological Operations (Dr. Giles). Cliniques: Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X-Ray (Dr. Pirie). 3 p.m.: Medical In-patient (Dr. G. P. Chappel). Demonstration of Cases of Fever (at the North-Eastern Fever Hospital, St. Ann's Road, N.): Dr. F. Thomson. 4.30 p.m.: Throat Operations (Mr. H. W. Carson).

Friday April 10th.

Royal Society of Medicine (20, Hanover Square, W.).—4.45 p.m.: General Meeting of Fellows of the Society: Ballot for New Fellows.

Royal Society of Medicine (Clinical Section) (20, Hanover Square. W.).—8.30 p.m.: Short Papers by Dr. J. Graham Forbes and Dr. F. Langmead: Fatal Lymphocythæmia in Early Life; and Dr. Francis Hawkins: A Case of Multiple Rheumatic Nodules in an Adult.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—4 p.m.: Mr. R. F. Bickerton: Clinique. (Eye.)

Appointments.

Barris, J. D., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer at the City of London Lying-in Hospital.

Cooper, H. G., M.B., B.C.Cantab., Public Vaccinator for the Altrincham District of Cheshire.

Fedden, W. Fedde, M.S., M.B.Lond., F.R.C.S.Eng., Surgeon to Out-patients at the Kentish Town Department of the Hampstead General and North-West London Hospitals.

Herapath, Charles Edward Kynaston, L.R.C.P.Lond., M.R.C.S., Junior House Surgeon at the Bristol Royal Infirmary.

Kemp, Charles Gordon, M.B., B.S.Durh., L.R.C.P.Lond., M.R.C.S., Resident Casualty Officer at the Bristol Royal Infirmary.

Pirie, W. Rattray, M.B., C.M.Aberd., Assistant Physician at the Aberdeen Royal Infirmary.

Smith, G. F. Darwall, M.B., B.Ch.Oxon., F.R.C.S.Eng., Physician to Out-patients at the British Lying-in Hospital, Endell Street, London.

Troup, Arthur G., M.B., Ch.B., D.P.H.Aberd., Assistant Pathologist at the Sussex County Hospital, Brighton.

Whitehead, A. E., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Bridlington District of the county of York.

Vacancies.

County of Lanark.—Middle Ward Isolation Hospital.—Resident Physician. Salary, £150 per annum, with board, etc. Applications to the Subscriber, W. E. Whyte, District Clerk, Hamilton.

Ayr District Asylum.—Junior Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and laundry. Applications to Dr. McRae, Glengall, Ayr.

Borough of Cambridge.—Medical Officer of Health. Salary, [illegible] per annum. Applications to J. E. L. Whitehead, Town Clerk, Guildhall, Cambridge.

Stirling District Lunacy Board.—Medical Superintendent of the District Asylum, near Larbert. Salary, £700 per annum, with house, etc. Applications to James Dobbie, Solicitor, Clerk to the Board, 3, Port Street, Stirling.

Manchester Royal Infirmary.—Resident Medical Officer of the Convalescent Hospital, Cheadle. Salary, £150 per annum, with board and residence. Applications to Walter G. [illegible], General Superintendent and Secretary, Manchester Royal Infirmary.

County Council of Cumberland.—County Medical Officer of Health. Salary, £700 per annum. Applications to C. B. Hodgson, Clerk, The Courts, Carlisle.

Joint Counties Lunatic Asylum, Carmarthen.—Second Assistant Medical Officer. Salary, £160 per annum, with board, lodging, washing, and attendance. Applications to W. Morgan Griffiths, Solicitor, Clerk to the Visitors, Carmarthen.

Edinburgh District Asylum, Bangour Village.—Second Assistant Physician. Salary, £120 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent, Bangour Village, Uphall.

Richmond Hospital, Dublin.—A Throat Surgeon; third Assistant Physician, and a third Assistant Surgeon.—Immediate applications to A. Smith, Secretary and Superintendent. (See Advt.).

Cambridgeshire, etc., Asylum.—Second Assistant Medical Officer. Salary, £120 per annum, with board, lodging, and attendance in the Asylum. Applications to T. Musgrave Francis, Clerk to the Visitors, 18, Emmanuel Street, Cambridge.

Births.

Farnfield.—On March 31st, at Mere, Wilts, the wife of William Walter Farnfield, M.R.C.S., L.R.C.P., of a son.

Wells.—On April 2nd, at Orleans Lodge, Twickenham, the wife of Arthur G. Wells, M.B., B.S. (Lond.), M.R.C.S., of a son.

Marriages.

Gillett—Bancroft.—On March 30th, at Wilmington, Del., U.S.A., Henry T. Gillett, M.D., of 15, King Edward Street, Oxford, to Lucy Bancroft, second daughter of William P. Bancroft, of Wilmington, Del., U.S.A.

Hammand Fraser—McMullen.—On April 2nd, at Brixton Independent Church, London, David Hammand Fraser, M.A., M.B., B.C., of Herne Hill, London, to Annie Isabel, second daughter of William McMullen, L.R.C.S.I., etc., of Brixton Road, London.

McBride—Hulbert.—On April 2nd, at Stephen's Church, Ealing. Walter, son of P. McBride, M.D., F.R.C.P.E., and F.R.S.E., of Edinburgh, to Lillian, daughter of Maurice C. Hulbert, J.P., of Ingleside, Ealing.

Williams—Robson.—On April 4th, at St. George's, Hanover Square, W., Commander H. P. E. Tudor Williams, Royal Navy, only son of Colonel H. P. Williams, of Rhayader, Radnorshire, to Phyllis Margaret Mayo, second daughter of A. W. Mayo Robson, D.Sc., F.R.C.S., of 8, Park Crescent, Portland Place, London, W.

Deaths.

Brown.—On March 30th, at Summerlands, Heathfield, Sussex, Alfred Brown, M.R.C.S.Eng., L.S.A., formerly of Wandsworth, in his 83rd year.

Lecky.—On March 31st, at the Sussex County Hospital, Brighton, Henry Collier Lecky, M.A., M.B., D.P.H.Oxon., aged 29, second son of John Lecky, of Putney.

If in doubt—
as to the best food to prescribe to delicate or rickety children, try an eighth or quarter of a teaspoonful of "Lemco" in half a pint of warm milk. Children who cannot digest milk often experience no difficulty with it when combined with "Lemco".

EUSTACE MILES
PROTEID FOOD

THE MEDICAL PRESS, April 1st, 1908, says—

"These foods purport to be both rich in nourishing constituents and easily digestible, and our experiments show that these claims are amply justified. We find the 'Emprote' Proteid Food to contain a large amount of proteid matter. The Cocoa contains a much larger amount of proteid matter than is to be found in ordinary cocoas—the actual percentage of proteid as found by us being 27.9 per cent. It contains a satisfactory small amount of moisture (4.7 per cent.) and 6.8 per cent. of mineral matter The amount of matter soluble in water is very high, viz., 47.3 per cent., which is about 30 per cent. more than is normally found in cocoas."

HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin
with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

☞ Extremely useful in **Rickets, Scrofula, General Debility, Anæmia, Weak Heart, Neurasthenia,** and Convalescence from illness such as **Pneumonia** or **Influenza.**

☞ Unsurpassed as a **Strengthening Restorative in Diseases of the Lungs.** Has a very agreeable taste, and is taken with the utmost relish even by Children.

FREE FROM BACTERIAL GROWTH. UNCHANGED BY KEEPING.

These important qualities are guaranteed by using the highest permissible temperature in the process of manufacture (130° to 140° Fahr. for 24 hours). No guarantee of this description is possible for preparations made by a cold process with ether.

☞ In prescribing, always state "HOMMEL'S" Hæmatogen as spurious imitations are offered. ☜

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - - Take from Half to One Teaspoonful twice a day in milk.
Children - „ One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.
Adults - - „ One Tablespoonful twice a day **before** the two principal meals.

☞ **SAMPLES AND LITERATURE,** *gratis and carriage paid, on application.*

T.H.E.

"The expedient of peptonising food is one of the most rational, scientific, and practical advances of modern medicine, and has been proved devoid of the slightest theoretical or discernible objection."

PANOPEPTON

Presents the entire nutritive substance of prime lean beef and best wheat flour converted into a soluble, completely and freely assimilable form.

PANOPEPTON

Is instantly and wholly assimilable and sterile.

PANOPEPTON

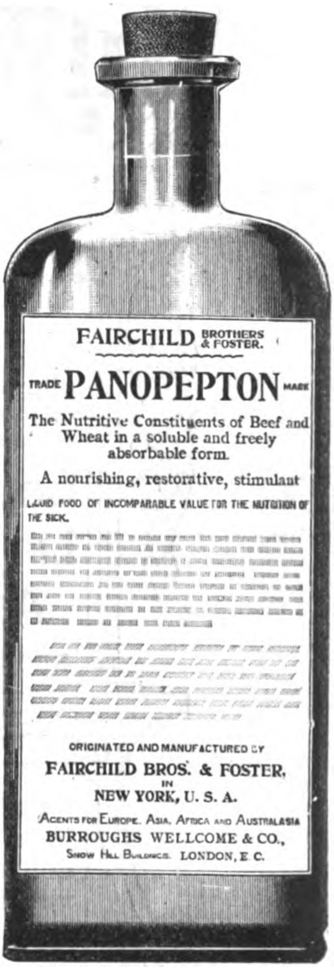
Contains all the extractives, salts, and savory matters of the beef juice, which are of peculiar value as stimulants.

PANOPEPTON

Contains all the proteids of the beef and wheat in a soluble non-coagulable form.

PANOPEPTON

Is a complete food, containing the albuminoids, carbohydrates and phosphates—the flesh, fat, and bone making elements.



FAIRCHILD BROTHERS & FOSTER.
TRADE PANOPEPTON MARK
The Nutritive Constituents of Beef and Wheat in a soluble and freely absorbable form.
A nourishing, restorative, stimulant
LIQUID FOOD OF INCOMPARABLE VALUE FOR THE NUTRITION OF THE SICK.

In all disorders of the respiratory tract in which inflammation or cough is a conspicuous factor, incomparably beneficial results can be secured by the administration of

Glyco-Heroin (Smith)

The preparation instantly diminishes cough, augments expulsion of secretions, dispels oppressive sense of suffocation, restores regular, pain-free respiration and subdues inflammation of the air passages.

The marked analgesic, antispasmodic, balsamic, expectorant, mucus-modifying and inflammation-allaying properties of **GLYCO-HEROIN (SMITH)** explain the curative action of the Preparation in the treatment of

Coughs, Bronchitis, Pneumonia, Laryngitis, Pulmonary Phthisis, Asthma, Whooping Cough

and the various disorders of the breathing passages.

GLYCO-HEROIN (SMITH) is admittedly the ideal heroin product. It is superior to preparations containing codeine or morphine, in that it is vastly more potent and does not beget the bye-effects common to those drugs.

Dose. — *The adult dose is one teaspoonful, repeated every two or three hours. For Children of more than three years of age, the dose is from five to ten drops.*

Samples and exhaustive literature bearing upon the preparation will be sent post paid, on request

NOTES AND COMMENTS.

Blackfriars on the Warpath. IT almost seems that the key to the prevention of unqualified practice lies in the hands of the Society of Apothecaries, for that ancient company is possessed of powers against those who infringe the rights of its members, such as no other professional body is armed with. The trouble has been that these powers, like the law against Sunday trading and the right of a Bishop to licence midwives, have been in abeyance so long that they are correspondingly difficult to enforce. It is, however, hopeful to see that the Society is now apparently actuated by a spirit of greater enterprise, and that it is putting its powers to the test of the law courts. Last week a herbalist, one William T. Gregory, was before Judge Tindal Atkinson at Edmonton County Court as defendant in an action brought by the Apothecaries' Society to recover a penalty of £20, for "attending, advising, and supplying medicines as an apothecary" in a particular case. As ill-luck would have it, this case was one of a poisoned hand, and the defence put in was the herbalist acted as a surgeon, which is lawful, and not as an apothecary, which is unlawful. The judge held that this defence was good, because the patient suffered from an injury from an external cause, and the case was of minor import. The action was consequently dismissed.

Apothecary or Surgeon. As the patient died from blood-poisoning, it is difficult to say which is the more commendable institution, a judge who classes the loss of human life in a "minor" category, or a law which allows a man to be mutilated by a quack, but not dosed except by an apothecary. The exact extent of an apothecary's sphere is very difficult to define at this period in the world's history, when people have long ceased to "use the 'pothecary," and have taken to "sending for the doctor." The modern general practitioner who dispenses his own medicines is, we take it, the nearest representative of the man who, in his day, was little more than a prescribing chemist, but to get a conviction it would probably be necessary to prove that the offender both attended a patient and furnished him with drugs. In spite of the ancient quarrels between the apothecaries and the surgeons, it is, however, beyond doubt that it was well within the apothecary's function to attend to minor surgical cases, such as cut fingers and crushed toes, as well as ailments, such as venereal diseases which, for some esoteric reason, are now classified with surgery. Although the Society of Apothecaries lost this case, we sincerely hope they will not be discouraged now that they have put their hand to the plough, as there is nothing likely to win greater recognition and gratitude for their company than the wholesale and rigorous prosecution of all unqualified pretenders to medical skill and knowledge.

Legal and Canine Specialists. THE manner in which the legal mind looks at quack practice may be gauged by another case heard last week. The Veterinary College, likewise galvanised into activity, obtained a conviction against a "canine specialist" for acting as a veterinary surgeon, and the defendant appealed. Legally, there was no doubt of the justice of the conviction, and the Court of three judges before whom the appeal came had no alternative but to uphold it. That they did so with reluctance was shown by the comments made by two of them, Mr. Justice Ridley and Mr. Justice Darling. The former of these gentlemen said that in his experience just as good advice was to be had from a canine specialist as from a qualified veterinary surgeon; and the latter that, "he reluctantly followed his brother." Mr. Justice Ridley doubtless is painfully aware that his opinions only carry weight in virtue of the position to which it pleased his friends to call him, but even he might possibly understand that there are certain advantages which accrue to a community through having its professions stocked with persons of certain guaranteed acquirements and under certain disciplinary control, and that though it may not be impossible that a layman could conduct a case in court, or give legal advice better than certain barristers, at the same time it is generally admitted that practice at the bar should not be thrown open to any squalid adventurer who cares to thrust himself forward.

The M.D.U. at Clerkenwell. ALTHOUGH the independence of the judiciary is considered a cardinal doctrine of the constitution, it often puzzles people why certain individuals should be raised to a place above their fellows, where they can with impunity give vent to any opinion they choose, without the object of their strictures having any remedy against them. Quite recently Judge Edge had before him in the Clerkenwell County Court a case in which a Miss Cropper sought to recover from Dr. F. H. Stokes, of Canonbury, the sum of £17. It was alleged by her that a cheque for £42 had been given to the defendant on the understanding that the sum claimed would be refunded out of it. Dr. Stokes denied that any such agreement had been made. The judge, in giving his decision, took occasion to state that he did not believe a word of Dr. Stokes's evidence, and refused him leave to appeal. Happily, owing to the action of the Medical Defence Union, it was arranged that a memorial should be presented to the judge by Mr. Dickens, K.C., setting out the grave dishonour which those remarks imputed to Dr. Stokes, and the impossibility of a gentleman of his position and character going into open court and committing gross perjury. The memorial was signed by many leading members of the profession. Judge Edge said that in all his life he had never heard of such a proceeding, but that he was glad to have the memorial, because if he had unintentionally done a wrong to Dr. Stokes he would be glad to set it right. He then made some comments on the memorial, and finished up by observing that he was willing "to accept the explanation" that Dr. Stokes's' memory had failed him as to the facts that had taken place. One must be grateful that even this tardy reparation was made, and we congratulate Dr. Stokes and the Medical Defence Union on obtaining it; but the incident only serves to emphasise the desirability of His Majesty's judges performing the duties for which they were appointed without indulging in speeches, comments, and witticisms at the expense of the parties who appear before them. The habit is a growing one, and we do not remember any period in history since the time of Judge Jeffries when such unbridled license was given to their tongues by judges on the Bench. This fashion does not conduce to the more effective administration of justice, and it sets an exceedingly bad example to the bar.

Removal of the Heart.

The marvels of modern surgery seem to have attained their climax at New York. According to the American Correspondent of the *Daily Express,* the most daring surgical operation ever attempted in America was performed at St. Joseph's Hospital on April 5th, and we are prepared to admit that if the description given is true it was certainly the greatest triumph over natural difficulties of which we have ever heard. The report given states that a certain athlete was stabbed in the heart during a street row and carried to the hospital, where he was promptly placed on the operating table. His condition appears to have been desperate. "More out of scientific curiosity than any hope of saving Mr. Inglis's life, the surgeons removed a portion of two ribs, and then took out the heart." We like the moderation of the reporter in claiming that only "a portion" of the two ribs was removed, when "two entire ribs" would have sounded so much more dramatic, but even the exiguous knowledge of anatomy that is included in a general education might have sufficed to make a sub-editor pause before believing that a living human heart could be taken out through the space allowed by the removal of a portion of two ribs. However, three stitches were put in the heart and that organ replaced. Two hours later the patient was well enough "to describe the assault and identify the assailant." The item of news is headed, "What They Do in New York. Man's Heart Replaced." This is the sort of stuff which is served up to the readers of the journal which recently advertised itself as "the reliable Express!"

National Union of Public Health Authorities.

A meeting of the Provisional Council of the above Union was held recently at the Grand Hotel, London, for the purpose of considering the rules of the association and the transaction of other business. The draft rules prepared by the Chairman and the Hon. Secretary, after being carefully considered and in a few respects amended, were adopted and ordered to be submitted to a Conference of the Union to be held on May 28th at Caxton Hall, Westminster.

LEADING ARTICLES.

THE IRISH UNIVERSITY BILL.

Mr. Birrell must, on the whole, be warmly congratulated on the immediate success which has attended the introduction of his Bill for the extension of University education in Ireland. Protests have been made, and objections have been taken to many of its clauses, but there is an absence of any organised opposition, and this is no small success, when we consider the many and obvious pitfalls which lie in the way of any scheme that could be proposed. The Bill, as it is printed, is, however, as the President of the Queen's College, Cork, has pointed out, largely a measure for dissolving a number of existing institutions and for setting up a body of Commissioners who shall shape a number of new ones from the *débris* of the old. Present criticism may therefore be directed to the omissions of the Bill, to its fallacies as regards finance, to the constitution of the governing bodies of the proposed Universities, and, indeed, to the reasons for or against the scheme as a whole; but until the Executive Commissioners have been appointed and have drawn up their scheme for the creation of the new Colleges, it is obvious that the real and final criticism cannot be made. For this reason, it seems that once the principle of Mr. Birrell's scheme is admitted, the Bill becomes of very secondary importance to the constitution of the Executive Commission, and to the principles which it selects to guide it in the discharge of its duties. In the case of the University in Dublin, three of the Commissioners are to be appointed by the Crown, and four by the new Senate. The Belfast Commissioners are to be similarly appointed. We publish in another column a forecast which is generally accepted as representing, so far as it goes, the Senates of the two Universities. It is almost certain that, in the case of the University in Dublin, the great majority of the Senate will be representatives of Dublin, and therefore we can quite understand the anxiety which the authorities of the Queen's College in Cork display as to the effect which the statutes of the Executive Commission may have on their College. All such statutes must, however, be placed before Parliament for final ratification before they become effective. Up to the present the main objections to the Bill have come from the Ulster Unionist Party, who object to the principle of watertight religious education compartments; from Cork, which objects to the non-establishment of a Cork University, on the ground that it is strange that a University is denied to the South, which asks for one, whilst it is forced on the North, which does not wish for one; from Magee College, because it has not been included as a constituent College of the new Belfast University; and from all the bodies concerned on the ground that the financial provisions are inadequate. On the other hand, the staff of the Queen's College in Belfast have adopted a series of resolutions, which our Belfast correspondent has summarised, and which unanimously express approval of the proposed establishment of a Belfast University.

PROPOSED PUBLIC HEALTH LEGISLATION.

In spite of the fact that the British national system of practical public health administration is probably the best in the world, it must be confessed that there is still room for improvement. The polluted state of many of our streams and rivers, for instance, constitutes a standing reproach to modern sanitary science. If we turn to individual slums, again, we find an appalling death-rate, and even yet such obvious questions as the eradication of tuberculous cattle, the control of the milk supply, and the lessening of a hugely disproportionate infantile mortality, have not been effectually dealt with. Under these circumstances, those who are interested in health problems will welcome the Bill which is being introduced into Parliament by Dr. George Cooper, for many years Chairman of the London County Council's Public Health Committee. His avowed aim is to amend public health administration so as to put an end to the gross neglect by local authorities of many essential sanitary duties. Nor is it possible seriously to gainsay his proposition that slums, public nuisances, and other sanitary evils abound all over the country, in spite of Acts of Parliament. In his attempt to remedy this defective legislation, Dr. Cooper proposes to apply several general principles. The first is to substitute compulsory for permissive powers wherever feasible. There can be little doubt that if this proposal were adopted, a vast amount of needful reform would be effected, as it were, by a mere stroke of the pen. In the projected Bill, County Councils are given full powers to bring to book local authorities neglecting their sanitary duties. This plan would probably be found more economical and more convenient than any attempt to enlarge the powers of a great central authority. The metropolis, which is a kingdom in itself, already has a municipal control over subordinate authorities in the special Public Health Committee of the London County Council. A further important matter dealt with in the proposed new Bill is that of payment of salaries. As a step towards relieving the medical officers of health and sanitary inspectors from local pressure, it is proposed that half the salaries should henceforth be paid by the County Councils. This condition would, of course, give the Councils a voice in the matter of dismissal of such officers, whom it would free materially from intimidation, acting now as a dead weight on the energies and the efficiency of an all-important class of public servants. Among minor details it is proposed to legalise the position of the health visitor, who constitutes an undoubtedly useful agent in the work of reforming the slums. One of the most noteworthy points in the Bill is that which makes it compulsory on every County Council to appoint a medical officer of its own. At present, many of the smaller county authorities have no such officer, while others take the part services of an officer jointly with another authority, or else they appoint one at a nominal salary. Dr. Cooper proposes that in future county medical officers should give their whole time to their duties and reside within their district. The reforms outlined in this useful and unassuming Bill have long been urgently needed, and we are glad to see that a practical measure has at length been introduced by a medical man. It is to be hoped that Parliament will find time to pass this most desirable piece of social legislation.

CURRENT TOPICS.

The Oral Use of Serums.

In The Medical Press and Circular of January 31st and Feb. 7th, 1906, we published an important communication on "A New Method of Serum-Therapy," by Dr. D. Montgomerie Paton. For eight years the writer had been studying, clinically and experimentally, the use of serums exhibited by the mouth. During that time he had used over twenty million units of anti-diphtheritic serum and forty gallons of simple plasma of the horse, sheep, and ox. This article made a short statement of some of the results obtained, but the writer hoped to put the whole work more fully before the profession in book form. In the treatment of over fifty cases of tubercle of all kinds the oral use of the simple plasma of the horse and sheep proved itself capable of transferring to the patient the resistance of the animal to the disease. On June 2nd, 1907, we published a further communication on above by Dr. D. Montgomerie Paton, confirming, as he pointed out, the results and conclusions published in his work, "New Serum-Therapy," (*a*) in which he advocated the oral use of serums, both normal and the produce of acquired immunity, for various diseases. We ourselves emphasised the importance of his work in the following terms:—"Among our original communications in the present issue will be found one of much interest from Mr. Montgomerie Paton, of Melbourne. It deals with the passive raising of the opsonic index by immune serum administered by the mouth. Last year the same observer published some original papers in the Medical Press and Circular upon the use of serums in many pathological conditions. His results were of a striking and suggestive nature. . . . . Should these observations stand the test of extended clinical experience they may possibly advance the science and art of serum-therapy by leaps and bounds." This being so, we confess to some surprise on reading the following paragraph in our contemporary (*b*), viz.: "We are informed that Dr. Latham, when reading the paper referred to in our issue of last week, under the heading, 'The Serum Treatment of Tuberculosis,' stated that the local and internal use of normal serum in many diseases characterised by tissue destruction was introduced by Dr. Hort, to whom he took the opportunity of expressing his indebtedness in connection with his paper." It will be a source of gratification to Dr. Paton to find that his original conclusions and work are confirmed in the independent work of others here; and though, anxious as our contemporary is to duly credit original work, they have overlooked the fact that Dr. Hort (*c*) himself, in a communication recently published states:

(*a*) "New Serum-Therapy." By D. Montgomerie Paton, M.R.C.S. Eng., L.R.C.P.Lond. Pp. 320. London: Bailliere, Tindall and Cox. 1906. Price 6s.

(*b*) The *British Medical Journal*, April 4th, 1908, p. 831.

(*c*) "The Therapeutic Uses of Normal Serum." By E. C. Hort, B.A., B.Sc., Univ. Paris, M.R.C.P.Edin. The *Lancet*, February 15th, 1908, p. 487.

"Since writing this paper I learn that in Australia a number of diseases have been treated by Dr. Montgomerie Paton with anti-diphtheritic and other serums administered by the mouth. The cases he has published seem to confirm amply the value of normal serum-therapy that I have independently arrive dat."

Cerebro-Spinal Fever in Dublin.

We referred a few weeks ago to the rumours that several cases of cerebro-spinal fever have occurred this spring in Dublin, and we hoped that steps might be taken to prevent a genuine outbreak of the disease. Unfortunately, we learn that the number of cases has greatly increased in the last few weeks, and there is grave reason to fear that Dublin is about to suffer as New York, Glasgow, and Belfast have suffered in turn. In the face of this situation it is of importance to inquire what steps the sanitary authorities are taking to deal with the situation. In addition to publishing quietist statements in the newspapers, we cannot find that they are doing anything. It is true that last week a special meeting of the Dublin Corporation was summoned to declare cerebro-spinal fever a notifiable disease; but those who know Dublin will not be surprised to learn that the necessary quorum to form a meeting did not attend. In all seriousness we wonder how long the citizens of Dublin are going to tolerate this official contempt for their lives. We think it was Whitman who spoke of the "tyranny of elected persons." Nowhere would he have found a better example of this tyranny than in the Dublin Corporation. It is not to be wondered at that the party of publicans and slum-owners which control that body should treat the lives of their constituents with indifference as long as those constituents are satisfied.

Proposed Memorial to the late Dr. Connolly Norman.

We desire to draw attention to a report which appears in another column of a meeting held at the Royal College of Physicians in Dublin during the past week with the object of initiating a movement for the erection of a memorial to Dr. Connolly Norman, the late highly-distinguished head of the Richmond Asylum. The secretaries of the committee appointed to draw up details of the proposed memorial are Dr. Donelan, the newly-elected Resident Medical Superintendent of the Richmond Asylum, and Dr. Fleury, from whom any further information can be obtained by those desirous of joining in this effort to perpetuate the memory of so distinguished an alienist.

Two Forthcoming International Congresses

Within the last few days the first circulars have been issued for two International Congresses—the International Congress on Tuberculosis, to be held in Washington in September and October of the present year; and the International Medical Congress, to be held at Budapest in August and September, 1909. The work of the former is divided into seven sections, viz.: Pathology and Bacteriology; Clinical Study and Therapy; Surgery and Orthopædics; Tuberculosis in Children; Social, Industrial, and Economic Aspects of Tuberculosis; State and Municipal Control of Tuberculosis; Tuberculosis in Animals and its Relation to Man. In addition to the discussions in the sections, an exhibition will form an important part of the work of the Congress. The International Medical Congress, on the other hand, will have its work divided into twenty-one sections, and the provisional programme is of the usual comprehensive character. It can hardly be claimed that Congresses of this catholic character do much to advance the cause of science. The most prominent men of science are absent, and the papers read are heard with little attention. As a means of promoting personal intercourse between scientific workers, however, they are useful, and we have no doubt that the Congress at Budapest will give a very pleasant week to those who attend it.

Adequacy of Poor-law Hospital Staffs.

The understaffing of many Poor-law Infirmaries has long been notorious, and undoubtedly lies at the root of various abuses. From time to time gross instances of the kind are brought to light, and the public newspapers are provided with a seven-days' scandal. There is no evidence, however, that the central authority has ever attempted to deal comprehensively with this important question. At the same time, it must be clear to the Poor-law Inspectors that many of the institutions it is their duty to visit are woefully understaffed, and it will be interesting to learn from the inevitable Royal Commission that will some day investigate Poor-law administration what steps they have taken to have matters remedied. On the other hand, it is not often that a complaint is made of overstaffing, even in these days of occasional palatial extravagance on the part of Guardians. Bristol appears to contribute one of these exceptions, if we may accept the statement of a Guardian, who said that two years ago the Poor-law Hospital had 117 inmates and a staff of 118. A few days ago he found 116 members of the staff to 100 inmates. The number of nurses was given as 51, an allowance that certainly seemed to be liberal, even allowing for an occasional influx of patients. While it would be a pity to check any reasonable provision for efficient nursing, the ratepayers have at the same time a right to demand a careful supervision of expenditure in that direction.

Vanishing Anthrax.

Anthrax is one of those diseases whose origin and natural history are so well known that its ultimate extinction is within the range of international prevention. In the United Kingdom we are happily free from endemic anthrax, and the majority of cases of the disease are due to imported wool. Not long ago a mysterious case was investigated by a Coroner's jury in the City of London, where a governess was found to have died from anthrax. The only probable route of infection appeared to have been infected food. Last week a case occurred in Bradford, where a wool-comber was found to have died from pulmonary anthrax. Deceased had to lift the wool, which came down a shoot, and place it in the washbowls. The premises were disinfected twice a day, and disinfectant was put in the washbowls. It is clear, however, that a workman thus engaged would be exposed to a certain amount of dust, which might readily be infected by anthrax bacilli. The jury made the commonsense recommendation that the bales of wool should be opened and steeped in disinfectant before being handled. The mere disinfection of bales, which was said to have been carried out in this instance, clearly had not destroyed the vitality of the specific organisms. It is interesting to learn that the large shop in which the case occurred has been free from anthrax for two years past, a fact which speaks volumes for the efficiency of modern methods of prevention in this dangerous trade.

Preventive Inoculation for Enteric Fever.

It seems not improbable that the future control over some, at least, of the specific infectious maladies will be by means of inoculations of various kinds. In the case of enteric fever there has accumulated a wonderful amount of evidence in favour of its preventive efficacy. Any special experience in that direction is therefore of much value. We note that in the *Journal* of the Royal Army Medical Corps, Lieutenant J. H. Graham reports recently that the 3rd Coldstream Guards (Egypt) were asked to undergo inoculation in the left flank against enteric and typhoid. The number who underwent the operation was 331, of whom only one contracted fever. Out of 381 uninoculated, 14 took fever, of whom one died. This is a sufficiently striking experience, and affords a lesson likely to be appreciated by the Army medical authorities. The saving of life among our Indian troops by the universal introduction of a really trustworthy preventive of enteric fever would be almost incalculable.

Another Resuscitation Fable.

Once again the newspapers have been flooded with paragraphs relating the wonderful story of a "return to life." It seems that the son of a Covent Garden tradesman residing at Brixton was seized with an epileptic fit, in which he was attended by a medical man. By some misunderstanding the relatives thought the latter said the patient was dead, and he was accordingly "laid out." Some little time afterwards he was found to be alive, and another fable of resuscitation was forthwith launched upon the world. On being summoned, the medical attendant said there was nothing unusual in the affair, and that when he left the patient on the first occasion he told the friends that he was practically "dead to the world." The narrative will no doubt find a place in the literature of those who are fond of parading the bogey of live burial. As a matter of fact, it is neither better nor worse than most of the fables they are pleased to put forward as evidence. It has often been insisted in our own columns that no single case of evidence that could absolutely establish the fact of live burial has hitherto been forthcoming. No case, that is to say, which could be said to be scientifically proved. Meanwhile every case, like that at Brixton, simply shows how extremely difficult it is to be buried alive.

PERSONAL.

The King has granted permission to Mr. A. F. MacCallan, M.B. (Cantab.), F.R.C.S., Chief Inspector for Ophthalmic Purposes under the Egyptian Government, to wear the Third Class of the Order of the Medjidieh, conferred on him by H.H. the Khedive.

By the will of Miss Mary Condar, the Royal Infirmary of Ryde benefits to the extent of £1,000.

Mr. R. J. Ranken Lyle has been appointed the first Professor of Midwifery in the University of Durham.

Professor W. D. Halliburton, F.R.S., of King's College, London, had the degree of LL.D. conferred on him by the University of Aberdeen.

A tablet, bearing an appreciative inscription, has been placed in the Royal Portsmouth Hospital to the memory of the late Dr. Alfred Lloyd Owen.

Lieut.-Colonel A. E. Tate, R.A.M.C., has been appointed Deputy-Assistant Director-General of the Royal Army Medical Corps at headquarters.

Mr. W. C. Bridgeman, M.P., Treasurer of the Hospital for Invalid Gentlewomen, has received an anonymous donation of £1,000 to the building fund.

The Graduation ceremony of Edinburgh University was held on April 10th, when the honorary degree of Doctor of Laws was conferred upon the Right Hon. Richard Caton, Lord Mayor of Liverpool.

Mr. J. Ward Cousins and Mr. Henry Rundle have retired from the staff of the Royal Portsmouth Hospital and been elected Consulting Surgeons. Mr. Ward Cousins has served on the acting staff for 48 years and Mr. Rundle for 34.

Mr. H. J. Hutchens has been elected to the post of Heath Professor of Comparative Pathology and Bacteriology at Durham University in succession to Dr. G. R. Murray, who has been elected University Lecturer in Medical Jurisprudence.

The First Lord of the Admiralty has appointed Inspector-General James Porter, C.B., M.D., to be Director-General of the Medical Department of the Royal Navy, in succession to Inspector-General Sir Herbert M. Ellis, K.C.B., K.H.P., F.R.C.S., LL.D., who has resigned.

At the Victoria Hotel, Manchester, on Saturday, Dr. Alfred D. Macnair was entertained to dinner by his fellow-practitioners in Broughton, upon the occasion of his leaving the district. After dinner Dr. Hamill, on behalf of the subscribers, presented him with an illuminated address which expressed the high esteem in which Dr. Macnair was held by his friends.

The Duke of Marlborough, K.G., has been appointed President of the English Committee of the First International Life-Saving Congress, to be held at Frankfort-on-Main early in June. Dr. W. Collingridge, Lieut.-Colonel Macpherson, C.M.G., R.A.M.C., and Mr. G. H. Makins, C.B., are among the other members. Mr. S. Osborn, F.R.C.S., is the Honorary Secretary.

Certifying Surgeons, Factory Act.

The following appointments under this Act have been made:—Dr. Thomas Pierse, for the Wexford district of Wexford; Dr. C. R. Wood, for the Shoreham district of Sussex; Dr. A. M. A. James, for the Kingscliffe district of Northampton. In consequence of the death of Dr. J. Servia, an appointment as certifying surgeon at Bellshill, in Lanark, is vacant.

A CLINICAL LECTURE

ON

THE CLINICAL VARIETIES OF CHRONIC RHEUMATISM.

By J. TEISSIER, M.D.,

Professor of Clinical Medicine in the University of Lyons.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE question of chronic rheumatism is still far from clear, in spite of the assiduous bacteriological and pathological research of recent years, and we are still constrained to look to clinical data for the purpose of classifying the cases described under this head. For this reason, although logically it would be preferable to limit the term chronic rheumatism to cases in which there is a history of a previous attack of acute rheumatism that has become chronic, we are fain to group under this term, at any rate, to begin with, all the clinical groups which it has become customary to comprise in the category of chronic rheumatism, including the joint affections which are generally admitted to be due to the influence of damp cold.

In this somewhat heterogeneous group we are enabled, by the aid of clinical analysis, to distinguish three groups of symptoms which are clearly defined: primary deforming arthropathies, running a regular, progressive, symmetrical non-inflammatory course, with a tropho-neurotic basis in the etiology whereof nothing can be invoked beyond damp cold; chronic joint affections consequent upon acute articular rheumatism or some infective disease (chronic infective rheumatism); and, lastly, chronic diathetic arthropathies dependent on intoxications and certain non-intoxications.

This classification, which is purely clinical and etiological, obviously differs little from that which, in common with Dr. Roque, I adopted in 1897.

The first of these affections, deforming polyarthritis, or "poor man's gout," comprises a group of symptoms clinically, if not pathogenetically, well defined. As a rule the joint manifestations are multiple with a progressive invading tendency, involving at first the small joints and passing on to the larger joints, invading successively and symmetrically the homologous members, and producing special deformities. These joint manifestations are almost invariably preceded by sensory disturbances—cramps, tingling and spasms—often lasting for many months. The joints are symmetrically involved, and present the familiar deformities with, in the larger joints, osteophytic growths and muscular atrophy. The periarticular tissues are thickened and infiltrated, the skin is smooth and shiny, as it were adherent to the bone, the synovial membrane is thickened, the cartilage undergoes velvety degeneration, and the bone is eburnated and decalcified. Skiagraphy shows the disappearance of the articular cartilages, while in places the bone is abnormally permeable to the X-rays. The muscles are atrophied, although there is no marked reaction of degeneration, the skin is also the seat of trophic disturbances, and neuritis in one form or another is often present.

This deforming polyarthritis runs a very characteristic course. There is a first period, lasting one or two years, which is characterised by sensory disturbances of the neuritic kind, slight fever, and diminished excretion of phosphates. The second period is marked by the steady invasion of the joints, which runs on for years. The third stage is that of immobilisation and cachexia. This stage is often complicated by Bright's disease, and these patients for the most part succumb to uræmic accidents unless they happen to be carried off by consumption, slow to develop, but with a rapid termination. Cardiac troubles are exceptional in this form. Endocarditis occurring in the course of chronic rheumatism is, I believe, restricted to rheumatism of the infective types.

This variety of chronic rheumatism is, in my view, a tropho-neurotic arthritis. Its clinical resemblance with nervous arthropathies, the symmetrical distributions of the joint lesions, and the tendency to hemiplegia appear to justify this view. Moreover, anatomical proof is forthcoming, for several of us have found well-marked meningeal thickening in such cases. We hold these lesions to be primary, and that the articular lesions are secondary thereto, so that the latter are of medullary origin.

This tropho-neurosis is probably of infective origin, although the specific germ has not so far been isolated. The lesions are non-inflammatory, but are essentially degenerative. With regard to the etiology, in addition to cold damp we must mention other predisposing causes: unhealthy surroundings, ancestral rheumatism, tuberculosis, etc. The last-named only acts as a predisposing cause in the cases under consideration, which are not tuberculous rheumatism, but para-tuberculous.

There does not appear to be an acute form of deforming poly-arthritis, the cases reported by Abrahams belonging, in all probability, to the group of infective rheumatism. The same remark applies to the chronic deforming rheumatism of childhood. Among the partial forms must be mentioned *morbus coxæ senilis*, an affection characterised by irregular deformities and good general health, although death from Bright's disease is always possible, and the vertebral form which requires to be distinguished from the true rhizomelic spondylosis, as described by Pierre Marie.

We will now pass on to the second group, that of chronic, post-infective arthropathies. These affect two forms: "chronic rheumatism" and "chronic infective pseudo-rheumatism," which correspond exactly to ordinary acute articular rheumatism and acute infective pseudo-rheumatism. Both in reality are of microbial origin, so that they present the same constitutional symptoms, and may be placed in the same category. The discovery of the affection now known as infective pseudo-rheumatism, after upsetting the classification of acute arthropathies has also modified that of chronic arthropathies, and it is at present generally admitted that every affection capable of setting up acute arthritis may further give rise to the chronic forms. We are thus confronted with a fresh series of cases of chronic rheumatism with deforming tendencies, varying in their clinical features according to the determining infection, but which may be classed together by reason of the nature of their complications (the frequency of visceral affections, more particularly endocarditis) and their anatomical distribution (special tendency to attack the synovial membranes and the peri-articular tissues, with marked tendency to ankylosis).

From a practical point of view, we must consider three common clinical types of chronic infective rheumatism: the true rheumatic form, the blenorrhagic form, and the tuberculous form.

The first variety, which was recognised by Charcot, Ball, and Bouchard, though controverted by the English school, appears to be tolerably frequent. As a rule the affection follows the acute form by sudden retrogression of the constitutional symptoms and limitation to three or four large joints. In this variety there are few, if any, sensory disturbances, and the resulting deformities are different. The damage bears specially on the synovial membranes, as can be seen by the aid of skiagraphy. There is no tendency to involvement of all the joints; indeed, we often witness a tendency to local improvement. But there is marked liability to endocarditis, especially mitral, but sometimes aortic. It may be stated that the presence of endocarditis in a young subject apparently suffering from deforming rheumatism is sufficient to establish the true rheumatic origin of the arthropathic syndrome. This true chronic rheumatism may be general or partial. If general, it may be grave in consequence of the extension of the process to all the peri-articular fibrous tissues and to the adjoining serous sacs as well as of the cardiac lesions. When partial, it may attack a large joint, the peri-articular tissue (scapular peri-arthritis), or the fibrous tissues (retraction of the palmar aponeurosis).

We must also admit the existence of cases of deforming polyarthritis (of the tropho-neurotic kind) in the subjects of past acute, articular rheumatism. In such cases we must suppose that the debilitating effects of the acute rheumatism have paved the way to the latter affection.

The blenorrhagic variety has long been known to us, with its peculiar tendency to involve the peri-articular tissues and its rapid course towards ankylosis, fibrous to begin with, but becoming osseous, whence the frequency of blenorrhagic rhizomelic spondylosis.

As in the preceding form, there are no sensory disturbances or amyotrophy, and no signs of compression. It does not necessarily run a progressive course, and marked improvement is not uncommon.

Tuberculous rheumatism, first described by Poncet, is almost always chronic, and is due to direct infection by the tubercle bacillus, or to the toxins elaborated by the latter; that is to say, a specific inflammation of the synovial membrane or a toxic inflammation of the periarticular fibrous tissues (arthropathy, which is histologically tuberculous or tuberculinous arthropathy). The relationship of this variety of chronic rheumatism with tuberculosis is quite clear. It occurs either in admittedly tuberculous subjects who present pulmonary lesions of a slow type, suffering, it may be, from typical white tumour; or else we find in the rheumatic subject a tuberculous lesion either apparent or latent; or it may be that the symptoms of chronic rheumatism make their appearance in a subject who is himself healthy, but whose ancestors or collaterals are largely tuberculous.

Tuberculous rheumatism assumes numerous forms, from slight local manifestations, the simplest form of local synovitis, to ankylosing rheumatism of the hip, or the common type of deforming polyarthritis, as well as the generalised form with invasion of the large serous cavities and ultimate explosion of miliary tuberculosis in the lungs. Just like blenorrhagic rheumatism, tuberculous rheumatism displays a marked tendency to ankylosis, which is, after all, only the expression of a general property of the tuberculous poison to set up adhesions in the serous membranes (especially the pleuræ and pericardium), and to induce tissue sclerosis. Here, too, the spinal column may be attacked and ankylosed (tuberculous spondylosis).

It is by no means an easy matter to establish the tuberculous origin in a case of chronic rheumatism. It may be clinically probable, but in most instances cultivations and inoculations of the synovial liquid fluid give negative results, cytological observations give uncertain data, and hæmatology throws little or no light on the subject. There remain the sero-reaction, which is of doubtful value, and the tuberculin test, which is risky. Skiagraphic examination shows nothing distinctive. We must, therefore, content ourselves with the clinical indication without being able to provide a more exact explanation of the pathology and pathogenesis of these tuberculous manifestations.

We may add that alongside tuberculosis and blenorrhagia there seem to be a chronic scarlatinal rheumatism and a syphilitic rheumatism, still little known.

We now come to the third category, comprising chronic arthropathies of toxic or auto-toxic origin. My own view is that these are not, properly speaking, cases of rheumatism at all. This can be shown by clinical analysis, which enables us to point to the differential characters of these affections, and to contrast them with those of true rheumatic arthropaties.

This group comprises all the chronic articular manifestations that occur as the result of poisons that are recognised to be liable to provoke inflammatory and trophic lesions of joints (alcohol, lead), and a whole series of joint deformities which are indubitably due to general auto-intoxication, from camptodactyly (rheumatism of gastric dilatation) to the Hippocreatic finger and biliary rheumatism, comprising also a long series of uricæmic deformities, deformities that range from Heberden's nodes, the most strictly limited form, to the most generalised forms of rheumatic gout and the arthropathies that are premonitory of interstitial nephritis.

These are constitutional diathetic manifestations. They stand in an indifferent relationship to the infection and are secondary at most. Cold damp may determine inflammatory outbreaks, but in reality the *primum movens* of the arthropathy is the constitutional disturbance due to auto-intoxication, and the nutritive disturbances thus engendered.

The features that distinguish them from arthropathies of infective origin are the following:—

1.—The morbid process never attacks the cartilage; at any rate, to begin with, on examining with the X-rays the inter-articular cartilages are seen to be in perfect preservation, in spite of well-marked deformities.

2.—The bony deformities, the swellings, and the nodular outgrowth become pale on the screen, and in the skiagraphic print they appear as white patches, showing their uric or uratic origin.

3.—The skiagraphic print may not reveal any precise modification of the kind. This means that the inflammatory tendency has been limited to the peri-articular tissues that alone share in the nodular deformity.

4.—These arthropathies are specially limited to the smaller joints, and show no tendency to generalisation. They are subject to outbursts betraying, it may be, striking alterations of size, and be associated with multiple visceral manifestations of the coexisting dyscrasia.

5.—Diathetic rheumatism is frequently accompanied by vascular, arterial and venous lesions; hypertension is the rule, renal sclerosis and aortitis, associated or not with Hodgson's inadequacy, are common, and there is an increase in the number of eosinophiles.

6.—This form of chronic rheumatism often gives rise to outbreaks of the nodular form, displaying a marked affinity for connective tissue, fibrous tissue and periosteum, etc., whence a very great variety of clinical forms dependent on the seat and the extent of the nodular outgrowths. All these manifestations find a ready explanation in the natural affinity of uric acid for white tissues, fibrous ligaments and aponeuroses.

Uricæmia, whether inherited or acquired, appears indeed to be the fundamental underlying cause of these various syndromes. The diathetic states thus caused belong consequently to the great arthritic family, of which, along with gout, they constitute the two principal manifestations.

This is why we sharply separate these arthropathies from the group of common rheumatic affections, and this distinction, which is of such great importance from the point of view of pathogenesis, is clinically indispensable since it entails altogether different diathetic and medicinal indications.

To sum up, true chronic rheumatism is of infective origin, but the infection may provoke arthritis in two different ways: (1) indirectly by trophoneurotic process, that is to say, by the primary action of the poison or the toxins on the central nervous system and the medullary roots; (2) directly by the action of bacterial poisons on the synovial membranes or the peri-articular, connective and fibrous tissues. Active infections tend to attack the joint forthwith; they have septicæmic tendencies, which are often revealed by heart lesions; this is infective chronic rheumatism. Infections that exert a slow but prolonged action act preferably on the nervous system, and it is through its intermediary that they produce trophic disturbances; this is tropho-neurotic deforming rheumatism.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Patrick Maxwell, M.D.Ed., F.R.C.S.I., Ophthalmic Surgeon to Jervis Street Hospital, Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin. Subject: "Internal Squint."*

HARVEIAN LECTURE.

SOME POINTS IN CONNECTION WITH THERAPEUTIC IMMUNISATION. (a)

By SIR ALMROTH E. WRIGHT, M.D., B.Ch.Dub., F.R.C.S.I.

THE Lecturer discussed first the importance of taking the opsonic index in cases which are to be treated by therapeutic inoculation. It was pointed out that vaccines must be used with care as regards dosage, and the ill-effects resulting from tuberculin inoculation, when it was first used for therapeutic purposes, served as an illustration of the dangers resulting from giving too large doses of vaccines. The determination of the opsonic index both before and after inoculation always serves as a useful guide as to the dose of vaccine to be given, and as to the time of giving it. If the index is not determined, then, for safety's sake, a very small dose of vaccine is usually given, and often the full beneficial effect is not obtained.

1. In some cases of staphylococcus infection, where there is a local visible lesion, *e.g.*, a boil or carbuncle, then the action of a given dose of vaccine can be observed by the local effects produced, and thus the dosage can be gauged; the same guide is present in some cases of tubercular lesion of the skin.
2. In some cases the pyrexia present serves as a guide to the therapeutic effect of the vaccine, but where the temperature becomes normal, often the lesion is not healed, and then the opsonic index is the only reliable guide to the dose to be used, This applies to the treatment of pulmonary tuberculosis by inoculation.
3. In some chronic cases, where the treatment is of long duration and the progress slow, *e.g.*, in tubercular disease of the joints, cases of cystitis, &c., the determination of the opsonic index is necessary as a guide to the dose and time of inoculation.
4. In some cases where the symptoms are latent and the lesion is not visible the index must be taken.
5. In cases where the disease is running a rapid course, *e.g.*, in septicæmia, there is danger in attempting to determine the dose of vaccine by the therapeutic effect produced for two reasons—(*a*) time does not admit of delay, (*b*) an excessive dose may be fraught with great danger. In these cases the opsonic index is the only reliable guide.
6. In some cases, a single dose of vaccine effects a cure, and here the experience of previous cases gives one an idea of the dose to use. If this is followed by the desired result, it is, of course, unnecessary to determine the opsonic index.

Sir Almroth Wright now proceeded to discuss some practical points relating to "The Pathology of Inflammation." He pointed out that there are two important factors to consider—(1) the emigration of the leucocyte (Metchnikoff's theory), (2) the transudation of lymph.

In cases of a local inflammatory lesion—

1. It is important that there should be a plentiful local supply of blood and lymph.
2. It is important that the blood and lymph should have protective substances.
3. It is important that a plentiful supply of healthy leucocytes should find their way to the local lesion.

Instances of the "Miscarriage of Inflammation" were furnished thus—

1. Where there is excessive serous effusion, and too few leucocytes as in a tubercular serous pleural effusion.
2. In abscess formation, where the leucocytes are dead, where the protective substances are absent from the fluid exuded, and where the digestive action of the fluid produced by the disintegration of the leucocytes has an inimical effect on the healing process.
3. Where a sinus or a fistula is produced, or in cases where there is much induration round a lesion the healing processes of inflammation are retarded by the adverse local conditions.
4. In cases where there is great dryness of the tissues affected by the inflammatory process the deficient supply of protective substances owing to the small amount of fluid exuded delays recovery.

The Lecturer gave many instances of the manner in which these miscarriages of inflammation could be remedied, *e.g.*, (1) by removal of excess of fluid in "serous effusion," and abscess; (2) the flushing of the local lesion in cases where there is a deficient

---

(*a*) Abstract of the Harveian Lecture delivered before the Harveian Society of London, March 26th, 1908.

supply of lymph to the part. This can be brought about by the administration of citric acid internally or by the local application of hypertonic solution of sodium chloride with sodium citrate. (3) Lastly, and most important, the protective substances of the lymph can be increased in amount by the therapeutic administration of an appropriate vaccine in proper doses.

LUMLEIAN LECTURES.

POINTS OF PRACTICE IN MALADIES OF THE HEART. (a)

By Sir JAMES SAWYER, M.D., F.R.C.P.Lond.,
Senior Consulting Physician, Queen's Hospital, Birmingham, &c.

LECTURE III.

In the frequent admixture in practice of functional disorder and of organic disease of the heart, in some cases the one of these, in others the other, is to the fore. So, in the true view of them, we have four great clinical groups of cardiac maladies. We have simply organic diseases; we have simply functional disorders; we have organic diseases complicated by functional disorders; and we have functional disorders complicated by organic disease. To these four groups, by the light of recent researches, we must add another —namely, one in which intrinsic functional disturbances of the heart's musculature are to be found. In practice, this is not always a distinct and separate group, because disorders of the cardiac musculature may complicate any of the four cases just distinguished. The healthy functioning of the heart depends upon several qualities in its muscular tissue. We have a myo-neurogenic explanation of the heart's working, in advance of the neuro-myogenic theory of the times just ago. In wasting diseases, in convalescence from acute diseases, especially from those of a pyrexial character, under the effects of various toxins, of autogenetic origin or of microbic infection, the vital qualities of the heart's musculature become impaired. In such impairment of those vital qualities we find the explanation of many cases of cardiac enfeeblement, of temporary valvular incompetence, and of temporary dilatations of cardiac cavities. In this wider conception of cardiac maladies, the observations and experience of the clinician enable him to distinguish unerringly to which group any particular case may belong, and this in most cases at once, or soon, in the others after longer watching. This complexity of cardiac maladies is what we find in practice. It would, indeed, be strange if disease of an organ so vital as the heart is in a patient's consciousness were not complicated by functional disturbance, of the kinds of such disturbance which are of emotional or of neurotic origin. Such disturbance is natural in the circumstances. And it is natural that the heart, linked as it is to many other organs by circulatory and by nervous connections, should be disturbed by extrinsic irregularities. Our therapeutics confirm this view. How often in practice do we omit the use of cardiac sedatives, of cardiac excitants, of cardiac tonics, of vaso-constrictors, of vaso-dilators, which so easily beset us, and all very useful when applied appropriately, to find such omission good, the heart's disturbance abated, and then to find the patient's comfort consummated under Gregory's powder, or under soda and calumba with an effervescent!

The nervous temperament, or nervous diathesis, as some prefer to call it, is the background, and, to change the metaphor, also the groundwork or basic principle, of most of the dynamic disorders of the heart. It is the basis of all the dynamic disorders of the organ, if there be excluded toxic causes, as the excessive use of tea or of tobacco, auto-toxic causes, as goutiness, and as what may be called copræmia from excessive fæcal retention, and also if there be excluded spanæmia, and also, what is little accounted of in these days, plethora, and also if there be excluded those disturbances of the myocardium which are marked by impairment of tonicity and of contractility in any part of that highly specialised musculature, and also if there be excluded certain rare cases of bradycardia, and of tachycardia, with or without exophthalmia. With these exceptions, the nervous temperament is the basis of the inorganic maladies of the heart. The recognition of that temperament is the clue to their successful management. In these affections the signs of the patient's disposition interpret the symptoms of his indisposition. A temperament is an individual peculiarity, a type of idiosyncrasy, of the physical organisation of a sentient and intelligent being, by which the manner of acting, feeling, thinking and suffering is affected permanently. Our definition of a temperament may include other beings besides human ones. For an instance: the manifestations of temperaments can be well studied in horses, and they may be studied in them with advantage to our understanding of those manifestations in our own kind. A temperament is a variant within certain limits of the natural organisation of living individuals. That there are temperaments in human beings is an ancient doctrine in medicine. Yet, that there is a nervous temperament is a notion which does not seem to have been uttered until fifty years ago. It might be regarded as a product of our later civilisation. But it seems to be a very old human characteristic, the differentiation of which has been recognised only in our own time. It was not until modern physiology had unravelled many of the mysteries of the nervous system that the marks of this emphasis of that part of our being could be distinguished. The wide diffusion of incomplete information is a note of our time; except for it, there appears not to be more nervousness now than of old. Dr. Pritchard, in his great essay on temperaments, published in 1835, described four temperaments, namely, the sanguine, the phlegmatic, the choleric, and the melancholic. (a) Dr. Laycock, lecturing in 1862, described six temperaments: the nervous, the sanguine, the phlegmatic, the bilious, the lymphatic, and the melancholic. He found that, "persons nervously active from predominant innervation are of the nervous temperament." (b) Such persons might be said to have a nervous system which is "highly strung." They have been said to be especially liable to nervous diseases. The truth would seem to be that they are no more liable to nervous diseases with "coarse" lesions than anybody else; but that all other nervous diseases are peculiarly their own. The phrase, a person of nervous temperament, and the words, a neurotic, are not of identical connotation. A neurotic person is one of this temperament in an extreme degree of it, or one in whom a nervous temperament of lesser degree is not under control. A neurotic is a person with one or more nervous symptoms. Such symptoms may be subjective, or they may be objective, or they may be both. These symptoms of the neurotic may be called neurotisms. All the dynamic maladies of the heart, other than those excepted just now, are marked by neurotisms, and have their essence in them. There are, too, the mixed cases in which functional disturbances blend, variously, with the signs and effects of organic disease.

Some persons of this temperament may be known by their eyes, with sclerotics unduly exposed, their eyes showing a breadth of sclerotic between the cornea and the upper lids—a sure sign, but one often absent. Temperaments appear oftenest in men. Few women show them decidedly. But when a woman is of the nervous temperament, in her it is well marked. Various temperaments may appear to be mixed in one person. A man of nervous temperament is quick in manner, if he have not a slowness which is obviously a calculated one; he may talk volubly and eat fast; he is apt to "overdo" everything into which his feelings enter, and they enter into most of his doings; he is apt for hobbies, and is often a collector of curiosities. If a good man, he is likely to make a worry of his goodness; if bad, he is apt for treasons and stratagems. Lingual physalisation is a name I suggest for a constant mark of this neuropathic type. When a patient of this temperament shows his tongue in the usual way, two broken rows of small air-bubbles are seen in the moisture upon its dorsal surface. Each row skirts the lateral edge of the tongue, and lies about a seventh of the width of the organ from this edge, a row of bubbles on each side. I have found this appearance in hundreds of cases. Its pathognomy is unerring. How does it arise? The Newtonian rule is safe, that we are to admit no more causes of a natural phenomenon than such as are true and enough. A little emotional increase in the viscidity of the mouth's moisture, as in fear, and a little emotional increase in the mouth's movements, as of swallowing, which is a physical accompaniment of what is called tenderness, and lingual physalisation results. There are other signs of this temperament. Laycock knew that temperamental signs could be made out from handwriting. A little study of the subject, accordingly to the modern French school of graphology, yields points of medical suggestiveness.

(a) Abstract of Third Lecture delivered before the Royal College of Physicians, London, Thursday, April 2nd, 1908.

(a) "The Cyclopædia of Practical Medicine." Edited by Drs. Forbes, Tweedie, and Conolly. Vol. IV. London. 1835.

(b) *Med. Times and Gaz.* 1862.

We recognise with one consent that each case of functional disorder of the heart needs its own particular treatment, in medicines, in dietetics, in education, and in self-discipline. If we can cure worry, that undue solicitude which Shakespeare called,

"A hell-hound that doth hunt us all to death"—

if we can cure worry, we are far towards the cure of many cardiac neurotisms. Worry is curable in a large proportion of instances, and that permanently. Often worry is only a continued form of impatience. The line of impatience in each case must be found, and the patient taught to develop resistance thereunto. He can develop such resistance in most instances. Worry usually is wearing and destructive. For the most part patients are to be helped against it. At the same time, experience in practice reveals that there are some worriers to whom worry appears to be a vital necessity, and in whom it is not to be resisted with advantage. How great, how curative, how durable in neurotic affections is the power of a patient to overcome harmful worry, under sympathetic and judicious medical guidance, is not recognised sufficiently. Each of us will prepare for such patients his own simple, comprehensive, and assimilable forms of an optimistic philosophy. Many such patients can be set aright if we establish in them the pursuit of a sound ground-work for daily happiness, for example, as in Chalmers's formula, by their pursuit of "something to do, something to love, and something to hope for." As in most nervous ills, the physician should be an adroit inspirer of hope, and of the patient's desire of cure, and, believe, he will get it.

It has long been known that strong and excited action of the heart, especially in a woman of nervous temperament, may cause murmurishness of the heart's first sound, as that sound is heard at the apex of the organ, and even develop there a systolic murmur. In a case purely of this kind the signs of organic cardiac disease are wanting. The abnormal sound disappears as the excitement subsides, this change often occurring during auscultation, if the murmur be observed for a few moments. More recent work in practice has elucidated this dynamic endocardial murmur. Such a murmur has been called by Potain a "souffle de consultation." He noted it: as arising with an acceleration of the beats of the heart, without any modification of the respiratory rhythm; as accompanying emotional disturbance, with the heart of normal size, and the pulse, although rapid, never irregular. Such is Piatot's account of the matter. (*a*) This is the murmur which might lead an incautious observer to a diagnosis of mitral insufficiency where no such inadequacy exists. I find this souffle de consultation is always systolic; it is to be found usually only in the mitral area, at and about the impulse point; it comes and goes under auscultation, that is, it alternates under observation, with a pure first sound; sometimes it is heard in the aortic area, too, and there, too, it is intermittent; very rarely it is aortic in site alone. Further, it is to be heard that this murmur, when it occurs in the anterior mitral area, goes with, accompanies, and is synchronous with the first sound; it does not take the place of that sound there, as the true murmur of mitral regurgitation does. The souffle de consultation is recognisable as an addition to a weakened first sound. The murmur of mitral regurgitation replaces the valvular part of the first sound and masks the muscular portion of that sound. We know that the murmur of mitral regurgitation is audible usually in the left vertebral groove; in rare instances it is inaudible there. But the mitral souffle de consultation is limited, almost always, to the impulse point; it may also be audible at the inferior angle of the left scapula, but only with the extremist rarity. One may think that this bellow's puff of emotion, when it is mitral in place, arises from some perversion of the muscular part of the heart's first sound, or from insufficiency of that part of mitral closure which is ruled by the papillary muscles, or from both, under an emotional disturbance of cardiac innervation. When this puff is aortic in area, the fine edges of the aortic valves may give for the moment a sonorous vibration to the blood passing the aortic orifice; one may opine that such an error of the lunulæ "getting in the way" would arise from arterial spasm.

Mitral insufficiency is the most frequent of all the chronic valvular affections of the heart. It is more frequent in practice than all the other valvular diseases of the heart put together. Mitral regurgitation, dependent upon organic mitral insufficiency, is marked by well-known physical signs. With some exceptions, such insufficiency is the mark of a lesion which had its local beginning in an acute rheumatismal endocarditis, usually, or in a mild form of other microbic endocarditis, rarely. Such endocarditis is exudative and proliferative in its processes, with the organisation of new products. The valves become thickened, hardened, and bound by adhesions, and a chronic endocarditis, leading to sclerotic changes, sometimes follows the acute process. Sometimes, but in my experience very rarely, the endocarditis appears to be in a chronic form from its outset. Whenever the characteristic murmur of a mitral insufficiency marking endocarditis may appear, it has come to stay. Instances of its disappearance are almost unknown. I have never known one. It must be admitted, however, that complete recovery without any valvular damage is possible, especially in young subjects, and especially after prolonged rest and quiet in bed. Potain gives the good name "holosystolic," wholly systolic, to the murmur of mitral regurgitation, so clearly and cleanly does it go with the ventricular contraction. The murmur is strong, often rough, often like the noise of a jet of steam, of equal course, with no maximum. Its tone may be high from the first, especially in young subjects, and its pitch lowers progressively, accordingly as the insufficiency increases or the myocardium fails. (*a*) Sometimes, though rarely, mitral regurgitation, as it is declared by its murmur, exists for many years without any other consequent abnormality whatsoever. A lady is still under my observation who has enjoyed this very exceptional immunity for about forty years. If with the murmur there be any other of its associated abnormalities, say, in pulse, size of heart or of liver, other complications are sure to follow. Usually the period of complete compensation is brief. We notice how much longer this time is in the well-to-do, with sobriety and light work, than in our experience of hospital patients. This malady is a typical disease of the heart. Sooner or later the valvular lesion causes hyposystole, arterial hypotension in the greater circuit, arterial hypertension in the lesser circuit, with cardiac dilatations, venous stases, hepatic, renal and other congestions, œdemas and dropsies.

Accentuation of the part of the heart's second sound which arises at the mouth of the pulmonary artery and is best heard in the "pulmonary" area, found and taught by Skoda in early stethoscopy, is an expressive sign of organic disturbance in the heart's dynamics. Its interpretation is significant in practice.

(*a*) "Traitment des Maladies du Cœur par l'hygiène et les agents physiques." Par M. le Docteur A. Piatot. Paris. Steinheil. 1898.

(*a*) "Sa tonalité, élevée dès le début, surtout chez l'enfant, s'abaisse progressivement à mesure que l'insuffisance s'exagère ou que le myocarde faiblit." Traitement des Maladies du Cœur, &c. Par M. le Docteur A. Piatot. Paris. 1898.

in diagnosis, in therapeusis, and in prognosis. This accentuation is an unfailing token of rise of tension in the pulmonary artery, of a threatening change in a vital circuit of the blood, which is beyond those tactile and metric tests which try variations of tension in systemic arteries. In health, the second sound is louder in the "aortic" area than in the "pulmonary." A louder pulmonary second sound marks some obstruction in the pulmonary circuit. It is like the banging of a door which before was closed with little sound. This sign is united with lesions of the mitral valves and of the mitral opening. Either insufficiency of the mitral valves or narrowing of the mitral opening, or both, add a new hindrance to the blood stream in the lesser circulation. In so far as such a hindrance elicits increased systolic force in the right ventricle, by so much does it raise tension in the pulmonary artery, and so accentuate the pulmonary second sound. Old mitral regurgitation or old mitral stenosis, or both, may be without this accentuation, or even with a pulmonary second sound less loud and clear than in health. This may arise from failure of the right ventricle, or from tricuspid regurgitation, or from both. In mitral disease, when the right ventricle at last fails to countervail the obstacle in the left side of the heart, the tension in the pulmonary artery falls, and with it the loudness of the pulmonary sound. When, too, in mitral disease, the tricuspid valves fail in their office, tension in the pulmonary artery falls. It would seem that this quasi-compensatory tricuspid regurgitation arises from widening of the ring of insertion of the valve, in the course of dilatation of the right ventricle, so that the valve cannot close the enlarged opening. In mitral disease, in the comparison of the pulmonary second sound with its aortic concurrent, we note that the aortic second sound is weakened relatively by the lowered systemic tension which results from mitral defects. Thus there is a pseudo-accentuation of the pulmonary sound. Such sound of normal loudness is not to be judged accentuated because it co-exists with a weak aortic sound. Hence a difficulty in practice which only long experience can solve; but it solves it quickly and surely. My observations lead me to conclude that the presence or the absence of accentuation of the pulmonary second sound, or a high or a low degree of such accentuation, are valueless in a diagnosis between mitral stenosis and insufficiency. Each of these variants of mitral disease, whether singly or howsoever blended, adds an obstacle in the lesser circuit, and tends to increased tension in the pulmonary artery. So long as this obstacle is countervailed by the right ventricle, so long is the pulmonary second sound louder than in health. When this saving force fails, as by dilatation of the right ventricle or by degeneration of its walls, or by both of them, then the pulmonary sound fails too, and may be almost lost, or quite. When mitral disease first arises, the pulmonary second sound accentuates, but slightly only. During the usual period of quasi-health, from the time of convalescence from the usual initial acute endocarditis until the time of other complications, the sound remains but slightly reinforced; during this period, which may vary from a few weeks or months to a few or to many years, it is usually as loud as the aortic sound, or a little louder, but not so markedly. Towards the end of this time, when tension in the pulmonary artery is nearing the point of prevailing over the compensatory force of the right ventricle, accentuation becomes very distinct, and reaches its loudest range. Then this sign is a grave one. It marks a height of tension not likely to be borne long. Then, as a straw upon the back of a labouring camel, some little effort or difficulty breaks down compensation. A little bronchial catarrh, and compensation fails, accentuation falls, viscera and surface congest, anasarca comes, and dropsies. Then by rest, by suitable evacuants, by indispensable digitalis, patients are likely to lose these later sequelæ of their mitral disease. As such an one improves, the pulmonary second sound swells again, as the right ventricle recovers its countervailing. With a rising sound comes recovery. But the complications of this later stage of mitral disease cannot always be removed even once; and if removed once, or oftener, at last treatment gains little or nothing. Then compensating powers are finally overcome; the pulmonary second sound strengthens no more.

In the removal of the congestive and dropsical complications of advanced mitral disease, my experience confirms the therapeutic efficacy of the well-known combination of powdered leaves of digitalis, with squill and blue pill. I have found that one pill, containing a grain each of the powder of digitalis leaf, of powdered squill, and of the officinal blue pill, given thrice daily, suffices usually. In some cases a larger proportion of digitalis in the pill is necessary for the good effects of the remedy; in such the dosage of the drug should be increased, under skilful guidance and observation. This pill is often quoted as Baillie's pill, of the great Matthew Baillie, of this College. His pill, however, contained, in his own words, "five grains of the pilula hydrargyri, combined with one grain of the dried powder of squills and half a grain of the dried powder of digitalis," and he prescribed it in hydrothorax, when, as he wrote, "dropsy of the chest does not depend upon any diseased structure of the heart." (*a*) The powder of the leaf, in pill, and the infusion of the pharmacopœia, have proved, in my practice, to be the best forms of administration of digitalis. Therapeutics, so far as it concerns the treatment of patients by drugs, in organic diseases of the heart, and especially in that condition of those diseases in which what we know as compensation is at fault, turns very largely upon the questions, in what case to exhibit digitalis, how to do so, and in what case to withhold it. Some sterling rules of practice in these particulars were reached by Withering, and laid down by him in his classical book upon the foxglove. (*b*) These rules have been refined since, notably in the distinctions between renal and cardiac diseases and dropsies, and generations of physicians of long practice have come to much clearness in the indications for the use of this great remedy. Digitalis is by far the best of the remedies of its kind. What it can do some other remedies can do in part; but none even that part so well. Digitalis has no succedaneum. As to when to give it or not, my own practice is, never to give it unless the indications for its use are complete, never to give it merely because the heart is affected; but to give it always, and then in efficient doses, when the veins and the arteries at the same time point to its use, namely, when the veins are too full and when the arteries are not full enough, and the pulse is soft.

Phlebotomy is necessary in danger of death from distension of the right cavities of the heart. In such a case I have seen the moribund saved by venesection. In such cases the old proud claim has been realised, *multos mortis e faucibus eripimus*. The more sudden the distension the greater the need for blood-letting. As the blood flows from the opened vein, the engorgement of the systemic veins, and consequently the paralysing distension of the right side of the heart, are diminished effectually; the right ventricle becomes able to propel its contents through the lungs, and so a fair supply of oxygenated blood is given to the brain and to the cardiac musculature. A cardiac cavity is a hollow muscle like the urinary bladder; hyperdistension of either results in its paralysis, with full retention of its contents. It is in cases of chronic bronchitis and pulmonary emphysema complicated by dilatation of the dextral cardiac cavities, that mortal danger most frequently arises from engorgement of the right side of the heart. In hospital practice I saw a woman, a chronic bronchitic, æt. 50. Upon becoming an in-patient her lips were bluish, with distended veins of neck, with orthopnœa, small and feeble pulse, lower extremities and hands œdematous, cardiac dulness increased transversely, with diffused impulse, hepatic dulness increased, sibilant and sonorous rhonchi all over chest, with large crepitations at bases of lung, and with scanty urine, one-fourthly albuminous. In four days she appeared to be moribund, labouring, with tracheal râles, for her

(*b*) "An Account of the Foxglove and some of its medical uses, &c." By William Withering, M.D., &c. 1785.

breath, with lips and tongue now purple, face deeply congested, veins of neck greatly distended, continued orthopnœa, and radial pulse irregular and almost imperceptible. The right median basilic vein was opened, and six ounces of very darkly coloured blood taken. The relief was at once; the pulse became regular and of fair volume, the dyspnœa lessened much, and also the venous distension, and the lips and face resumed an almost normal hue. In a fortnight she left the hospital—her œdema gone, and her urine free from albumin.

Within the thirty years last past, therapeutics in cardiac maladies have evolved two peculiar remedial procedures of importance, in certain varieties of physical training, and in certain respiratory exercises. Before that time rest usually was pressed in chronic heart cases, with no idea that any form of movement could be salutary. As to the forms of physical exercises, Oertel, in 1875, following ideas which Stokes had expressed, advised muscular exercises; these he arranged in the form of walking up slopes, in progressively augmented ascensions, and to these he added a dietary restricted as to fluids.

A physiological appreciation of the various forces concerned in the circulation of the blood makes clear the physical foundations of the remedial employments of respiratory exercises. The use of these exercises is indicated strikingly in many cardiac maladies, in organic diseases of the heart, and in neurotic disorders of the organ. In the latter I have found them aidful in assuaging the cardiac consciousness. Such exercises for cardiopaths appear to be of our own times. They are usually helpful in any form of hyposystole, and especially are they adjuvants to the blood flow in the pulmonary and hepatic circuits. I have found much benefit in practice from the twice daily use of frictions, prolonged for a few minutes, of rubefacient embrocations to the skin over the heart.

The remedial uses of alcoholic stimulants, under judicious guidance, in many heart cases are well known. The power of alcohol, when suitably exhibited, to evoke and to sustain the action of the heart's musculature is well established. I have found alcoholic remedies especially useful in practice in cardiac maladies when combined with spicy aromatics and anti-spasmodics, and I think we might revive the use of two good old cordials—of two old and good hearteners, usquebagh, which was officinal in the pharmacopœia of the College in 1677, and ipocrasse, which is a tincture of ginger and other spices in red Burgundy.

ORIGINAL PAPERS.

NOTES ON A CASE OF

GRAVES' DISEASE TREATED BY THYROIDECTOMY. (a)

By WILLIAM TAYLOR.

As the treatment of Graves' disease still remains in a somewhat unsettled state in this country, I thought it might be of interest to bring the notes of the following case before this section of the Academy, and add some remarks upon the surgical treatment of this condition.

M—— K——, a dressmaker, æt. about 24, was admitted into the Meath Hospital under my care on April 7th, 1906.

Her history was as follows:—On December 26th, 1900, she noticed that her left eye seemed to be larger and more prominent than the right. Her colour, which had hitherto been good, altered very noticeably. Her face seemed to become generally swollen and the skin assumed a greenish hue. Six months after the left eye was noticed to be prominent her right eye also became prominent, but the prominence never seemed quite so pronounced as that of the left eye. At this time she developed an insatiable thirst, and used to drink enormous quantities of water. She likewise developed an inordinate desire to eat sweets. Her heart began to trouble her, and palpitations became very distressing. She could scarcely sleep at night on account of the rapid, tumultuous beating of her heart, and her mother was unable to occupy the same bedroom with her on account of the violence of the heart's action. Then her neck became swollen, the enlargement appeared first on the right side, and gradually extended across the front of the neck. Nervousness made its appearance. She became easily frightened, dreaded going out of the house at night, and she began to give way easily to tears. In short, as she told me, she became "hysterical." She was compelled to give up cycling to business because of her nervousness, her palpitations, and the breathlessness from which she suffered on the least exertion. Even when walking to business she was compelled to stand still for a few moments on account of the palpitations and breathlessness. Ultimately she was unable to go to business, and she became very depressed and got into very low spirits. Neuralgic pains now appeared in her head and face. Her stomach and feet became swollen—her feet so much so that she had to remove her boots on getting to business. Her hands likewise became swollen so that she experienced difficulty in putting on her gloves. Loss of memory was noticed, and she developed a dislike towards and a feeling of distrust and suspicion of her friends. Her temper became very irritable. She had some dysphagia, and occasionally experienced a sensation of suffocation. Her face flushed frequently, and she often perspired profusely.

She felt a throbbing sensation in the back of her neck, and complained of severe headaches. The latter were so severe that she thought she would go mad. Her hands became very tremulous, and she had a tendency to let articles drop. At the same time she frequently felt her legs suddenly give way, and felt that they were unable to support her. She complained of pain over her heart, and once over the left eye. When very ill she slept badly, and always awoke in great fright. She was restless, and tossed about in bed. Her appetite was generally good; she vomited occasionally, and complained at intervals of abdominal cramps. The bowels were constipated. There was amenorrhœa. She frequently felt feverish and weak. Dr. Lennon saw her, and took her into the Meath Hospital, where she remained for some two months, and for six months subsequently she followed his advice and took the medicines he prescribed. She improved for a time, and then relapsed. The patient attributed her condition to a fright she received on the Easter Monday prior to the onset of her symptoms, the fright being produced by a car upon which she was driving being almost upset. From that day she felt nervous.

The condition on admission to hospital was pretty much as described in the history she related, and which I have just detailed. She was kept quiet in a private ward for some three weeks, and during this time her pulse varied in frequency from 120 to 136 beats in the minute. Belladonna and digitalis were administered during this period. She was exceedingly tremulous, and her agitation and nervousness were so pronounced that she could scarcely speak intelligibly. The urine contained neither albumin nor sugar. Operation was performed on May 7th, a hypodermic injection consisting of morphine 1-6th gr. and atropine 1-100th gr. being given half an hour prior to the administration of the anæsthetic, which was chloroform. There was nothing unusual in the operation, which consisted in the removal of the right lobe, which was greatly enlarged, and with it almost the entire isthmus. The pulse for the subsequent 24 hours varied from 120 to 140, and the temperature rose to 101.4°. On the second day the temperature was normal, and the pulse fell to 120 again. Convalescence was uneventful, the drainage tube was removed on the third day, and the sutures on the sixth day. The pulse gradually fell in frequency until the tenth day, when she left for the convalescent home. On this day I found the record was 78 pulse beats, but, on counting it myself, it varied from 80 to 84 in the minute. The patient has since expressed herself to me as feeling better than she has felt for many years. The eyes are still prominent, but much less so than they were before operation. She has no palpitations, her muscular tremors are gone, and she is scarcely more nervous than any young girl would be whilst being medically examined.

(a) Paper read before the Surgical Section of the Royal Academy of Medicine in Ireland, February 28th, 1908.

Graves' disease, until comparatively recently, was generally looked upon as coming more within the province of the physician than the surgeon. I need scarcely trouble you with a list of the drugs usually prescribed. Phosphorus is probably the best of them. Naturally, we should have expected the somewhat fashionable animal extracts to have had their advocates. Not only have these been shown to be useless, but some of them, such as thyroid extract and ovarian preparations, have been shown to be positively dangerous. Cases treated from their initial stages by these preparations progressed rapidly from bad to worse. The beneficial effects ascribed to drugs would probably be more correctly attributed to the rest in bed and to the quiet to the nervous system generally.

More recently Lanz endeavoured to neutralise the poison in the patient's system by feeding his patients upon the milk of goats whose thyroid glands had been previously removed. He reported several cures. The outcome of this line of treatment was the production for the market of a powder of milk called rodogen. This powder supplies, or is supposed to supply, the principle conveyed by the milk of the thyroidectomised goats. The experience of other observers does not bear out the wonderful effects for these lines of treatment claimed by Lanz and his followers. In any case the treatment is not curative, but simply palliative. Professor Schlesinger, of Vienna, says his experience of the treatment of Graves' disease by the milk of thyroidectomised goats and by rodogen is negative, and not worth further consideration. The effects of treatment by injection of blood serum derived from sheep whose thyroid glands had been removed is thought to be more beneficial.

The operative treatment of this strange disease has undergone many transformations. Division of the isthmus of the thyroid gland, and even its excision, had their devotees some years ago. The operation of ligature of two or more of the thyroid arteries claimed its followers, but the most empirical of the operative procedures suggested and practised pretty extensively by some surgeons was that of sympathectomy on one or both sides of the neck. Considering the conflicting ideas that prevailed concerning the pathology and causation of the phenomena, it is not surprising that the effects of these various operative procedures were far from convincing physicians that operation provided better results than their eclectic drug treatment. In truth, the one seemed just as empirical as the other. Even at the present time there will be no difficulty in finding surgeons who still consider Graves' disease essentially a physician's disease so far as treatment is concerned. Quite recently Mr. Berry expressed himself strongly in the *British Medical Journal* in that direction. Considering the modern ideas respecting the pathology and causation of the phenomena of Graves' disease, Kocher, C. H. Mayo, and many others, whose experience is such as warrants them in drawing trustworthy deductions therefrom, state that thyroidectomy in some form or other is the proper line of treatment for this disease. Kocher says, by taking away the diseased gland in due time, one can cure even the severest cases of the disease, as one thus removes the source of the mischief by removing the organ in which the disease has its localisation. When, however, secondary changes have taken place in the fatty tissues of the orbits and in the cardiac muscle, etc., the complete re-establishment to normal conditions is hindered. The degree of amelioration of the symptoms, Kocher says, is in direct proportion to the amount of hypertrophied gland tissue removed or destroyed by the operation—that is to say, in direct proportion to the amount of diminution of the functions of the gland. The preliminary treatment consists in rest in bed with or without the administration of phosphorus or belladonna for some time before operation.

C. H. Mayo has adopted, as a preliminary to operation in severe cases a course of exposure to X-rays, and in some such cases has had X-rays applied to the remaining lobe after operation, and apparently with beneficial results.

The mortality of any or all of these operative procedures was naturally at first high, but surgeons whose experience is great in this branch of surgery state that the operative mortality of Graves' disease will be but little in excess of that following partial thyroidectomy for simple colloid goître, provided the operation is undertaken before the patient's heart, muscle, and system generally have become degenerated by the toxic poisons circulating in the blood. The latest report of Kocher's operations to which I had access showed that he had only one death in his last 52 thyroidectomies for Graves' disease, and that one was due to secondary hæmorrhage—a preventible condition. C. H. Mayo, in his last report, states that he had only two deaths in his last 64 thyroidectomies for Graves' disease. In considering the question of mortality, before deciding upon operation one should consider whether the particular case is one primarily of Graves' disease, or whether the phenomena of Graves' disease have developed secondarily in a patient who had been the subject of an ordinary colloid goître for some considerable time before, as the mortality, so far as I am able to learn, seems much less after operation for secondarily developed Graves' disease, while the prognosis as regards complete and permanent cure after operation can be given with greater certainty.

The mortality after thyroidectomy for Graves' disease has been attributed to shock, to a combination of symptoms to which the name of acute thyroidism has been applied, to acute tetany and to the effects of general anæsthesia, as well as to pneumonia, sepsis and such accidental conditions. In five cases of death from acute thyroidism reported by one surgeon, albuminuria was present in all before operation. The condition of acute thyroidism has been attributed to the absorption of thyreotoxins, which escaped into the wound after division of the isthmus of the gland; to the absorption of toxic blood serum from the wound, or serum containing thyroid secretion in suspension, or to rough handling of the gland during operation forcing a considerable quantity of thyreotoxins into the circulation.

To obviate as far as possible the risk of this complication, one should handle the gland gently and expose it freely before actually handling it at all. Free drainage should be provided for 24 to 48 hours, and as little raw gland surface should be left exposed in the wound as possible.

If there is anything which increases absorption in a wound or gland, it is loss of blood; consequently one should endeavour to prevent this absorption by introducing a considerable quantity of saline solution immediately after the operation. Should some toxic absorption have already taken place, the free administration of saline solution would dilute the poison and at the same time stimulate the kidneys to eliminate it rapidly.

To what extent the removal of, or destruction of the parathyroids in the performance of thyroidectomy for Graves' disease plays a part in the subsequent mortality is at present uncertain.

Their removal or destruction seems to be accountable for the acute tetany which occasionally causes death after thyroidectomy.

Halstead believes that the surgery of Graves' disease centres in the problem of removing the greater portion of the thyroid gland without sacrifice of the parathyroid glandules. This can be done by following the *technique* recently described by C. H. Mayo. It consists in peeling the posterior capsule off the lateral lobe during its removal, thus leaving that portion of capsule with the parathyroids on its posterior aspect intact.

As medical treatment is generally considered useless, and as surgical treatment is shown to be curative by men of experience such as Kocher and C. H. Mayo in early cases, and of pronounced benefit even in advanced cases, surely, it is not asking too much of physicians who see these cases first to ask them to try the effects of surgical interference more frequently than they have hitherto done, and at an early period in the course of the disease.

OPERATING THEATRES.

VICTORIA HOSPITAL FOR CHILDREN.

Inguinal Hernia, with Presence in the Sac of an Appendix which had been Subject to an Attack of Appendicitis.—Mr. Joseph Cunning operated on a boy, æt. 3, who was suffering from right inguinal hernia. The patient had worn a truss for about a year, but as the hernia was still present, it was considered there was no prospect of its cure by aything but operative measures. At the operaion an incision was made over the inguinal canal; the fibres of the external oblique were slit up to the internal ring, and the sac was then isolated from the structures of the cord. On opening the sac it was found that the appendix was present in and was adherent to the sac. The adhesions were separated and the appendix pulled down. There were many adhesions between the appendix and the ileum, and between the appendix and the cæcum; these were separated, the meso-appendix ligatured, and the appendix removed by the purse-string method. The sac was then ligatured and removed. The internal oblique and the conjoint tendon were sutured to the deep part of Poupart's ligament behind the cord, and the external oblique was sutured in front of the cord. Mr. Cunning then remarked that nothing was known regarding the undoubted attack of appendicitis which this child had evidently been the subject of. This, however, was not remarkable, seeing how often attacks of appendicitis received the name of stomach-ache, colic, indigestion, etc. It was fortunate, he thought, in this case that the cæcum came down freely into the sac, for it enabled him to remove the appendix without enlarging the ordinary hernia incision. He had once before operated on what seemed strangulated hernia, but, on opening the sac, its contents were found to be pus and non-strangulated intestine, while at the upper end of the inguinal canal was found an acutely inflamed and perforated appendix. The intestine in this case was gently reduced and left lying within the abdomen at the site of the internal ring after gauze packing had been introduced to shut off the rest of the abdominal cavity. The patient made a good recovery. He remembered also another case about two years ago of strangulated hernia in a female infant, æt. 1½, in which the strangulated contents proved to be the tube and ovary, and the strangulation was of such a degree that he considered it advisable to ligature and remove the tube and ovary, and then suture the inguinal canal. With regard to the radical cure of hernia in children, he considered that the mere removal of the sac was sufficient to restore the inguinal canal to as good a condition as that of a normal unruptured person, and that the ordinary methods of repair of the inguinal canal such as were used in adults are not really necessary, though he still employed a few stitches as a precautionary measure. The difference between a hernia in a child and one in an adult was that the internal oblique muscle which is so important in the prevention of protrusion, is normal in a child, whereas in an adult who has had a hernia for a long time the muscle is stretched, and very often distinct intervals are found between its fibres.

The convalescence of the child operated on was uneventful.

Small-pox on a Clyde Steamer.

On arrival of the Anchor Liner *Olympia* off Greenock, on April 5th, it was reported that on the voyage from Bombay to the Clyde three cases of small-pox had occurred on board.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, March 27th, 1908.

The President, Sir Henry Swanzy, in the Chair.

TUBERCULAR JOINT DISEASE TREATED BY DENYS' TUBERCULIN.

Dr. Frank Dunne exhibited two patients suffering from this disease. A man, æt. 39, suffering from tubercular ulcer of lower third of leg and ankle-joint for five years, also several sinuses on both arms. An X-ray photograph showed extensive matting and pulping of bones of tarsus. All discharge ceased early in September last, and the patient had good use of his foot and both arms. The second patient, a girl, æt. 20, suffered from tubercular wrist for about three years, and both ankles for over two years. The wrist was scraped with little improvement. When treatment commenced this patient was very much run down. Temperature, 100-102°; pulse, 100; weight, 6st. 3lb. All discharge ceased early in June and temperature has not been above normal since. . X-ray photograph shows matting and pulping of every bone in wrist-joint, yet the girl has good use of the hand, and can walk perfectly. In both these cases treatment lasted for about a year. The man gained 1st. 9lb. in weight, and the girl 3st. 6lb. In both cases about fifty injections were given.

The Chairman said his practice had been confined to Koch's tuberculin, T. R. Denys' tuberculin appeared to be a very effective preparation, and he would like to know some details as to the method, and the indications as to dosage.

Mr. Lentaigne: It was a mistake to think that tuberculosis had not been cured in the past. He had seen numbers of cases that had got well of themselves. Recently he had had a large number of cases of complete cure, the time of which was measured by months, not by years, as in the cases exhibited. While expressing his appreciation of the good work done by Dr. Dunne, still he believed that the results would have been more quickly attained by surgical assistance. He himself was assisting surgical treatment by tuberculin, and he had found that Koch's tuberculin had not to be given so often as Denys'. Perfect cure had been obtained by gauging the injections by the opsonic index, but it was a difficult method, and he had seen no increased negative phase produced by calculating in a rough way the time of the negative phase of the previous injection. If the disease was found to persist or recur—and no one could say that the cases exhibited would not recur—they should look to the surroundings of the patient, as the question of environment was of great importance.

Professor McWeeney said the method for obtaining Denys' and Koch's tuberculin was the same up to a certain stage. Both grew the tubercle bacillus on the surface of a broth containing 5 per cent. of glycerine, and filtered off the bacilli. But Koch's method from that point consisted in evaporating the liquor of the culture to one-fifth of its original bulk, while Denys' used it without reducing it in volume. The difference, then, was that Denys' contained presumably toxic and presumably therapeutic materials which were easily destructible; these would be destroyed by boiling, in Koch's. The latter was more concentrated than Denys', but he was not aware of any difference in the dosage. Nowadays the tendency was to have a small dosage, and to avoid producing a reaction in a rise of temperature; in Koch's old system a rise was considered necessary. He had lately been working with tuberculin in ophthalmo-reaction. He used Koch's old tuberculin diluted to the strength of 2 per cent. This provided material for hundreds of patients at a cost of 8s. 6d. One drop produced the desired result. Contemporaneously with this he used the cutaneous reaction by inoculating both arms, the right with a drop of 25 per cent. of the old tuberculin and the left with 3 per cent. boric-acid solution. In a couple of cases he thought he noticed a marked therapeutic result from the method in the absorption of a pleural effusion, and in two other cases there was a distinct improvement in the symptoms. As the result of his experience of the opsonic index, he stated deliberately that, in his hands at least, he had never been able to convince himself that the errors of experiment did not outweigh the very slight differences from the normal obtained by means of the method, and he did not think he would attach any importance to opsonic indices obtained otherwise than by Wright himself, his immediate assistants, or those who worked for a prolonged period under his immediate supervision.

Mr. **M'Ardle** said that, while the theory with regard to the influence of tuberculin might be discussed by scientists, it was their duty, as practising surgeons, to take heed of what really happened. It would be impossible to carry out the serum treatment in many cases if they were obliged to have some one capable of taking the index at their elbow all the time. The treatment of the cases before them had been carried on in what might be called a haphazard way, but he had seen cases where, with the persistent employment of tuberculin, the patient rapidly put on flesh. He had seen laparotomies, for instance, carried out without beneficial effect, and after the injection of tuberculin the patients recovered, and were now quite well. He had seen a vast improvement in some of Dr. Dunne's cases—cases which were apparently hopeless —under the influence of tuberculin. But while tuberculin exerted a beneficial influence in such cases it exerted no influence, but a harmful one, once abscess formation had occurred.

Dr. **Dunne**, in reply, said he had no hope of being able to use the opsonic index, as he had too many patients, and too little assistance, to be able to do so. He was guided, as to the dosage, by the effect of the injection on the patient. That might be a temperature or a local reaction, but as much as possible he avoided a temperature reaction. If there was marked reaction he either left a longer interval or reduced the dose. He quite agreed that operative treatment would, in some cases, materially hasten recovery. He had about 90 cases under tuberculin treatment, and he found that he got the best results with small doses at short intervals. After three and a half years of using tuberculin he was firmly convinced that, as far as their present knowledge went, there was no treatment anything like equal to it for tuberculous affections, no matter where situated.

DIAGNOSIS OF IMPACTED CALCULUS IN THE URETER.

Mr. C. **Arthur Ball** read a paper on this subject, and gave an account of a case in which an erroneous diagnosis of impacted calculus in the ureter was made even with the assistance of an excellent radiograph, taken with a shadowgraph bougie *in situ*. The case was that of a man who had been operated on elsewhere six months previously for renal calculus. Since the operation all the urine from that kidney came through a fistula in the loin. A shadow by the X-rays of a supposed stone was found, apparently in the ureter; this was verified by several radiographs, and the relation to the ureter established by use of shadowgraph bougie. The ureter was exposed by an extraperitoneal iliac incision, but no stone was present. The ureter was dilated, and the final result was satisfactory. The origin of the shadow, which is still present, has not been established. Mr. Ball said the mistake could only have been avoided by a stereoscopic radiograph taken with a shadowgraph bougie *in situ*, and that in future he intended to make use of this method in all similar cases.

Mr. **M'Ardle** said they were accustomed to hear only of successes in the statistics of surgery generally, but Mr. Ball had followed the line taken by those who had placed surgery on a firm footing. The case was one of exceeding difficulty; the examination was carried out with extreme care, and the only thing in doubt was the "spot on the sun," which it would require time to determine. The paper was an exposition of the dangers of jumping at conclusions with regard to urinary troubles

Mr. **Wheeler** said the case had been formerly in his hands, and two X-ray photographs verified the diagnosis of renal calculus. After the stones were removed a catheter was passed into the bladder, and every care was taken to see that no calculus remained in the ureter. The urinary fistula gave him trouble, which he put down to using silk in order to get a firmer cicatrix and prevent a lumbar hernia; but the silk became infected, and bits came away. The shadow in Mr. Ball's skiagraph had developed since the man was under his care.

Dr. **Harvey** said the diagnosis was a very natural one, but, since the result was not what was anticipated, it would be interesting to see in what way the diagnosis could have been avoided. The shadow on the photograph was evidently some substance which was denser in the centre than at the periphery; that was not generally the case in urethral stone, nor was it oval. He understood that no urine was passing from the ureter, and in passing the urethral catheter it would appear to him natural to expect the catheter to be stopped by the stone.

Dr. **Lane Joynt** mentioned a case in which a shadow appeared in the neighbourhood of the base of the lung, and could not be explained, as the patient had no evidence of any lung trouble or history of old phthisis. Ultimately a diagnosis was made of calcification of the pleura. He quoted also a case of a deformed elbow —from an injury twenty-five years previously—in which a soft mass, like a hernia of the muscles round the forearm, gave a dense shadow like iodoform, though there was no history of any such drug having been used in the treatment.

Mr. **Gunn** said the line of the ureter varied a good deal, and it was difficult to conclude whether the shadow was really in the line of the ureter or not.

Mr. **Ball**, in reply, said the stone might not cause obstruction to the passage of the bougie, as it might act as a kind of ball-valve, and might be pushed upwards into the dilated ureter. There were no symptoms connected with the appendix. He would try and get a stereoscopic photograph.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Sheffield, March 27th, 1908.

The President, Dr. A. J. **Wallace** (Liverpool) in the Chair.

A **vote** of condolence to Mrs. William Walter, of Manchester, on the death of Dr. Walter, was carried.

Dr. **Miles Phillips** (Sheffield) exhibited a specimen of uterus bicornis unicollis, with atresia of the external os and absence of the vagina. The patient was 16 years of age, and had enjoyed good health up to October, 1907, when she began to suffer from pain in the right iliac region, and fever. She had never menstruated. Examination revealed a normally developed vulva, but there was no vaginal orifice, and per rectum a rounded, smooth, hard swelling, the size of a duck's egg, occupied the middle of the pelvic cavity. Under anæsthesia the lower pole of the tumour was reached by an easy perineal dissection, but the thickness of its wall resembled a uterine rather than a vaginal collection of fluid. The abdomen was therefore opened, and it was seen that the tumour consisted of the right enlarged horn of a bicornute uterus, together with a distended right Fallopian tube. The left cornu was rudimentary, and the Fallopian tube patent in only half its length. The uterus and appendages were extirpated, except the normal left ovary, which was saved. Recovery was complete and uneventful.

Dr. **Lloyd Roberts** (Manchester) showed a vaginal fibroma removed from a patient, æt. 46, who had had six pregnancies. The labours had always been difficult. She complained of painful and difficult micturition and an irregular sanious vaginal discharge. The tumour, which had a sessile attachment to the left vaginal fornix, was removed by enucleation.

Dr. **Briggs** (Liverpool) communicated a case of ACUTE COMPLETE INVERSION OF THE UTERUS, manually reduced on the 20th day after labour. The patient was 28 years of age, 4 years married, and had

had 2 miscarriages. The labour had been slow on account of premature rupture of the membranes, and the delivery with forceps under chloroform had occupied two hours. During the third stage fundal pressure had been used on account of severe hæmorrhage. For three weeks there had been febrile disturbance with one definite rigor the day before admission to hospital, severe abdominal pain and vaginal bleeding, dribbling and incontinence of urine. Vaginal douching of lysol had been carried out, but no examination made till the 19th day, when she was sent into hospital under the care of Dr. Briggs. On examination under anæsthesia the inverted ulcerated uterus lay in the vagina, and the ring of cervix was faint and sharp. The uterine cup became palpable bimanually, and reduction was effected by 20 minutes continuous increasing pressure gradually exerted so as to lift the body of the uterus through the thin cervical ring without damage. A douche of sterilised water at 120° was then given, and repeated twice daily for 7 days. Convalescence was tardy, with febrile disturbance, but the patient left hospital 8 weeks after the reduction of the inverted uterus.

Drs. **Briggs** and **Edmiston** narrated a case of

SEVERE ACCIDENTAL HÆMORRHAGE

occurring in a patient, æt. 26, v.-para, with a history of previous easy labours. During her present pregnancy she had had a great deal of worry, and said that she remembered falling on one occasion, but without serious consequence. At 11.30 a.m., March 6th, three days short of the full term, she was seized with severe abdominal pain and vomiting. At 7.30 p.m. the collapse became grave. She was pallid, cold and restless, pulse thready, 152 per minute, temperature sub-normal. The physical signs of a tense tender full-term uterus were present. Fœtal heart sounds were inaudible. Vaginally, the cervix admitted two fingers, there was no bleeding, and the examining finger could reach neither placenta nor blood clot. The membranes were unruptured, and labour pains were absent. In this condition she was admitted to hospital, and Dr. Briggs ordered morphia ¼ gr., and atropine 1-100 gr., hypodermically at 9.30 p.m. The patient slept five hours, and at 8 a.m. (March 7th) the pulse had fallen to 120. The hypodermic injection was repeated in three hours on account of restlessness, and the patient slept at intervals. The os now admitted three fingers. Shortly after midnight, March 8th, pains became pronounced, and a speedy and spontaneous delivery was completed; 2½ lbs. of clot and about a pint of fluid blood were expelled. The fœtus, which had been dead about a week, weighed 7¾ lbs. At the end of the third stage the pulse was 156, but gradually fell until the eighth day, when it rose to 140, and the temperature to 102°. The involution of the uterus had been slow. On the tenth day an intra-uterine douche of sterile water at 118° was given. The temperature fell to 97.8°, and the pulse to 112, gradually assuming the normal level. The points of interest are the entire absence of bleeding, the large size of the retro-placental clot, and the success of the treatment adopted. The amount of blood-clot amongst Goodell's cases with recovery was never above 2 lbs. In this case the retro-placental clot weighed 2½ lbs.

Dr. **Miles Phillips** related a case of

CONCEALED HÆMORRHAGE

at the fifth month of pregnancy, treated by vaginal hysterotomy. The patient had had nine children, the last 1½ years ago. Menstruation was regular, but the three periods before Christmas, 1907, were less in amount than normal, and the two periods since Christmas consisted of smart floodings with hypogastric pain. The last had ceased three days before she was seen by Dr. Phillips. The abdominal tumour extended to within 1½ ins. of the umbilicus. No fœtal parts or movements could be felt, and no heart sounds heard. Threatened miscarriage was diagnosed, and complete rest in bed enjoined. A week later the hæmorrhage recurred, and the patient was admitted to hospital. She looked very ill, and complained of severe abdominal pain. The uterus now extended 1 in. above the umbilicus. The pulse was 96 per minute. A laminaria tent was introduced into the rigid cervix, and rectal salines given. Five hours later, as she seemed to be getting worse, it was decided to evacuate the uterus, and under anæsthesia a transverse incision was made in the anterior vaginal fornix, the bladder separated, and the rigid cervix incised in the mid-line as well as 1½ ins. of the lower uterine segment. A large amount of old and recent clot was evacuated by the finger, and the intact ovum reached on the left side of the fundus was delivered. The blood was apparently in the decidual cavity. The incision was closed by catgut sutures, and a gauze pack left in the uterus. Recovery was uneventful.

Dr. **Gemmell** (Liverpool) read a note on

PRIMARY CARCINOMA OF THE FALLOPIAN TUBE,

based on a recent case, in which there was a history of profuse, watery, offensive vaginal discharge in a nulliparous woman, æt. 45. The physical signs led to a diagnosis of multiple uterine fibroids, with chronic inflammatory disease of the right appendage. Laparotomy revealed double chronic inflammatory appendage disease, right hydrosalpinx and left pyosalpinx. Subsequent examination of the specimen demonstrated that the left tube which was closed at its fimbriated end, sausage-shaped, 3 ins. in diameter, contained pus and an enormously thickened mucosa forming a papillomatous growth. Microscopically this proved to be adeno-carcinoma. Both ovaries were normal; the right tube was in a condition of simple salpingitis.

HARVEIAN SOCIETY OF LONDON.

A MEETING of the Society was held on March 26th, at 8.30 p.m., at the Stafford Rooms, the President, Mr. D'Arcy Power, F.R.C.S., in the chair, when Sir Almroth Wright, M.D., F.R.S., delivered the Harveian Lecture on "Some Points in Connection with Therapeutic Immunisation." An abstract of this lecture will be found on page 424.

CENTRAL MIDWIVES BOARD.

MEETING HELD THURSDAY, APRIL 9TH, 1908.

The **President** in the Chair.

THE first business—viz., the election of Chairman and Treasurer, resulted in Dr. Champneys resuming the chair, and Mr. Fordham continuing his appointment as Treasurer.

The report of the Standing Committee dealt with sundry correspondence referring to instruction for midwives, Dr. Nepean Longridge suggesting that they should possess some knowledge of the warning symptoms of uterine cancer. The Chairman undertook to draft a leaflet on the subject. In reply to certain letters from the Secretary of the British Medical Association, commenting on the Board's reference, in its letter to the Privy Council, to the hostility existing in some districts between medical men and midwives, it was stated that the matter referred to was founded on communications to the Board, on communications which have appeared in the *British Medical Journal and Supplement*, in the medical Press in general, in the nursing Press, and on facts within the knowledge of the Board.

Applications for approval as teacher were granted to Elsie M. Inglis, M.B., W. H. Wright, M.D., and to C. Vere Nicoll, M.R.C.S., L.R.C.P., and G. B. Messenger, L.M., S.S.A., *pro hâc vice*.

With reference to the Board's resolution of March 19th, that some action be taken in the matter of payment of fees to medical men called to the assistance of midwives, it was agreed:—(1) That the Privy Council be asked to furnish the Board with a return showing the Boards of Guardians which have adopted the suggestions of the Local Government Board in the Circular of July 29th, 1907. (2) That it be referred to a meeting of the Standing Committee to frame a statement on the subject; and (3) That when the return has been furnished the Privy Council be asked to receive a deputation of the Board on the subject of the payment of the fees of medical practitioners summoned to assist midwives in emergencies.

The **Secretary** furnished the Board with a statement as to the results obtained from his inquiry—sent to all the County Councils and Borough Councils in

England and Wales—respecting the number of midwives practising within their areas. Although there are only 135 County and Borough Councils, the Secretary had had to deal with 276 Local Supervising Authorities, owing to several of the Councils having delegated their powers. Six out of this number had not replied to the inquiry at all; in some cases where the powers had been delegated they had been repudiated by the authority to whom they were delegated, so that in those districts the Midwives Act was not being worked at all. The returns obtained cannot be considered absolutely reliable, especially as regards Wales, where, for instance, Anglesey is reported to have only one practising midwife, and Cardigan three. The total number in England and Wales, according to the returns, is shown to be 10,000, which, as the Secretary pointed out, is considerably under the correct estimate.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, April 12th, 1908.

Hypertrophy of the Tonsils.

Medical treatment can, says Dr. Guisez, in the *Journal des Praticiens*, when the tonsils are not too enlarged, give good results. The following gargle relieves the inflammation and acts as a slight antiseptic:—

Phenic acid, 15 gr.
Menthol, 6 gr.
Glycerine, 2 oz.
Cherry laurel water, 5 oz.

A tablespoonful in a glass of warm water, used as a gargle morning and evening.

In children too young to gargle, the parts may be touched with a mixture containing iodine or resorcin. The general treatment should not be neglected; it consists in cod-liver oil, iodide preparations, and sulphurous or arsenical mineral waters. The above treatment only succeeds where the hypertrophy is soft and of recent date, or where surgical treatment is counter-indicated by hæmophilia; or, in the case of epidemic infection (grippe, eruptive fevers, diphtheria).

Before proceeding to operate, the variety of the affection should be exactly recognised. Soft tonsils bleed but little; fibrous tonsils, on the contrary, frequently bleed profusely, from the fact that the vessels remain patent after the section. The form of the tonsils also commands attention (pedunculated or sessile). The bistoury may be employed in the pedunculated form, and in the spongy form observed in children, on account of the little danger of hæmorrhage. The galvano-caustic snare in children when the tonsil is pedunculated, or in the pedunculated fibrous form of adults. Removal by piecemeal is the method usually followed to-day, and is applicable to every case.

Ablation of the tonsil by the bistoury should only be employed by experienced hands; the tonsil is seized in a forceps and cut across by one stroke of the knife. A better instrument is the tonsillotome, but it is only applicable to children.

Removal by the galvanic red-hot wire is also employed with success, without fear of hæmorrhage as the vessels are cauterised during the passage of the wire. But the best method, according to Dr. Guisez, is that of piecemeal ablation.

The operation should be done under general anæsthesia for children, or local anæsthesia for adults. For this latter the region is painted with cocaine (1—20), and the anæsthesia is completed by two injections of stovain (1—100) into each of the pillars. After the tonsil has been removed by pieces with the forceps, the patient is given ice to suck, while iced drinks are ordered for 24 hours.

Vegetations of the Genital Organs.

Of all the means employed for destruction of vegetations of the genital organs, resorcin is the most efficacious. When they are isolated and pedunculated, it is sufficient to apply powder, pure or moistened with a little water, and covered with a compress. The applications are made every day until the vegetation dries up. When these papilloma are sessile and generalised, the following preparation is used:—

Collodion, 3 oz.
Resorcin, 6 dr.

Before applying the mixture, the parts should be washed with ether to remove any humidity which would hinder the adhesion of the collodion. After the first application the vegetations begin to wither up, and generally two or three applications complete the treatment. To avoid relapse, the patient is recommended to wash the parts with a weak solution of resorcin (½—100), and to powder with:—

Carbonate of zinc, 2 dr.
Subnitrate of bismuth, 2 dr.
Resorcin, ½ dr.
Fuller's earth, 3 oz.

Treatment of Aortic Aneurysm.

The palliative treatment consists in rest, lacto-vegetarian diet, the ice-bag over the region of the aneurysm, and injections of morphia.

For the curative treatment, iodide of potassium or sodium, mercury (if syphilis is suspected), chloride of calcium and gelatine.

Chloride of calcium is a good coadjuvant, and should be given in 20-grain doses three times a day.

Gelatine should not be given by the mouth, as it is transformed into peptone in the stomach. Lancereaux proposed to administer it subcutaneously:—

Gelatine, 2½ dr.
Bicarb. of soda, 2½ dr.
Water, 1 quart.

This solution should be sterilised. From 2 to 6 oz. might be injected once a week, and for a long time.

GERMANY.

Berlin, April 12th, 1908.

At the Medizinische Gesellschaft, Hr. His read a paper on

Medicine and Over-culture.

He started from the point that "nervosity" was a very widespread disease, and brought it into dependence on our social and cultural conditions. He thought we lived in a state of over-culture. He looked on subjectivism as the sign of our times, and as dominating all the spheres of our culture. Without altogether denying the influence of heredity, he believed that as an ætiological factor it was much overestimated by many. Moebius saw the chief cause of it in the modern means of intercourse, on the one hand, our spiritual aspirations towards the true, and the neglect, associated with it, of intellect.

As a reaction from our over-culture, a striving for a return to simplicity and nature was noticeable, arising out of a repugnance to the present conditions of culture. From this arose the various "Nature" methods of treatment, which were of the ages, and which were again brought to light. The speaker glanced at the histories of other epochs in which a period of highest culture was followed by one of over-culture. The period of the later renaissance was an exception to this. From this, as well as from the depressions that followed the Thirty Years' War, as well as the downfall of Prussia at the commencement of the last century, we learnt that prosperity alone could not be "nervosity," but that something else belonged to it—viz., security, freedom from danger to body and life. Over-work played a lesser part. This was a relative term; with a constitutional disposition it might lead to the injury of the individual, but never to an epidemic outburst.

Those called to improve these conditions were the physicians, who must take the best they could for combating the disease wherever it might come from. The most important was psychical treatment. An object must be placed before the nervous, the weak-willed, however small the circle it might benefit, and when it was accomplished we should have put new life into his self-consciousness, have strengthened his will, and increased his pleasure in life. Valuable, as had been emphasised on many sides, as was the support of religion, it was not a question of "confession" or denomination, but of faith where one submitted to a higher will.

For obviating the security it would naturally be false in principle to wish to bring war and misery about us, but in the time of peace it behoved us to play at war. For this, military service was of the greatest advantage. All kinds of games and bodily exercises were also of great use. The speaker concluded by appealing to physicians to be not only the bodily but also the mental advisers of their patients; these, however, must be brought to see that their organisms not only consisted of different parts, but that they were complete entities, and that they should not run to a different specialist for each separate disease, but should place their trust in their family doctor.

At the Verein für Innere Medizin, Hr. Zinn related a case of

Pulmonary Metastases in a Case of Epithelioma of the Chorion.

The disease occurred in a woman, æt. 31, and ran a seven-weeks' course, with symptoms similar to those of miliary tuberculosis. She was admitted into hospital with hæmoptysis, cyanosis, dyspnœa, and moderate fever. For about four weeks the expectoration was hæmorrhagic, muco-hæmorrhagic, sometimes more purulent. There were attacks of exacerbated dyspnœa, fever, and cyanosis. There was slight dulness at the apices of the lungs, diffuse fine râles, the latter bilateral, later on. The menses had appeared two months before; vomiting was frequent, as in the first pregnancy. The uterus was two finger-breadths above the symphysis. The case was taken to be one of miliary tuberculosis. Four weeks after admission the first bleeding from the vagina took place. It was repeated, and was profuse at times. A number of rounded bluish growths the size of cherries were found in the vagina; some were broken down and bleeding. The uterus was the size of the fist, movable and anteflexed. A portion excised showed the characteristic signs of chorionic epithelioma. Operation on the gynæcological side was declined on account of the pulmonary symptoms. Improvement took place under treatment with Fowler's solution and atoxyl, but the patient died 3½ months later with symptoms of cerebral hæmorrhage.

At the autopsy the lungs showed numerous metastases the size of peas, and larger equally disseminated through the lungs. There were several nodules in the uterus, and a smaller one in the vagina. In the posterior lobe of the brain was a fresh hæmorrhage into a cerebral metastasis. The typical structure of chorionic epithelioma was seen in the microscopic preparations, both in the excised portion from the vagina and also from the metastases in the brain. In some of those in the lungs there were marked retrogressive changes—necroses—and but few typical tumour cells. A similar condition was present also on the uterus. There were plainly spontaneous processes of recovery in progress, such as had been described by many authors.

Of all tumours, chorionic epithelioma afforded the most frequent metastases in the lungs—in about 41 per cent. This was the result of the growth of the tumour into the maternal vessels. The frequent participation of the lungs without any sign from the genitals was of importance for the clinician. The diagnosis was difficult in such cases, but less so when there was early vaginal hæmorrhage. The patient had passed a vesicular mole two years before.

In view of the tendency to spontaneous recovery the treatment should be surgical, and the uterus should have been removed. Only in that way could the sources of the metastases have been cut off, and those in the lungs were not a contra-indication of operation.

AUSTRIA.

Vienna, April 12th, 1908.

Acromegalia.

Hochenegg presented a patient at the Gesellschaft, æt. 30, on whom he had operated for a tumour in the hypophysis. The patient suffered from a severe form of acromegalia when brought to hospital, but immediately after the removal of the tumour the acromegalia began rapidly to disappear.

Exner thought there was something wrong in the logic of this disease. It has been affirmed that the function of the hypophysis is lost when acromegalia appears. Now this operation must have destroyed, or at least partially destroyed, the function of the hypophysis; yet all the symptoms of acromegalia disappeared, which is a contradiction in terms.

Redlich said he looked upon the disease of acromegalia as a hyper-function of the hypophysis, and not a loss of function, as sometimes affirmed. In the light of extirpation curing the disease, this theory is easily understood.

Perennial Horns of the Deer.

Grosz next brought in a male deer, which he had castrated, with the horns peculiarly placed as if the animal had on a peruke or periwig. This he assured the members was the result of castration. In all his experiments he found the horns fell off the next week after the removal of the testes, this was supported by perennial imitations which gave the animal an appearance of wearing a periwig.

He next exhibited two horns, one taken from an animal he had castrated, the other taken from another whose testes had been destroyed by injury to the organ. Both of the horns resembled each other in appearance and constituents.

Khautz remarked that the formation of this peruke was not always the sequence of castration, and argued for an exception to the rule.

Tandler thought the principal characteristic of this peruke after castration was the formation of a covering integument that persisted and never was shed as in the healthy animal.

The Rays and Syphilitic Exanthemata.

Ehrmann showed a patient who had suffered from a persistent syphilitic papular exanthemata which he had cured with the ultra-violet rays. Photos confirmed his statements. He commenced with the right shoulder on February 25th and 26th; in the right groin on February 27th and 28th; and on the forearms on March 4th. Photos of the two sides were now shown, as well as those before application. The gummata, as well as the syphilides, had undergone absorption, and this after three or four applications, or within four days. He considers this an effectual cure for local syphilis.

He brought forward a patient he exhibited to the members in January last who was then suffering from erythrodermia exfoliativa, with a blood anomaly of 32 per cent. of eosinophile leucocytes with enormously enlarged glands. After four radiations of the inguinal region and two of the supra-clavicular glands the swellings subsided, and the cutaneous symptoms disappeared. The blood constituents are quite changed, and the eosinophile cells reduced to 27 per cent., and the mononuclear increased from 1.7 per cent. to 11 per cent.

Squamous Epithelial Carcinoma.

Menzel showed a patient with a perfectly initial primary squamous epithelial carcinoma of the soft palate about the base of the uvula. Around the hard area a few nodules could be found, giving an irregular appearance to the surface. The histology and diagnosis were determined from excised sections.

Lang thought many of these surfaces had flat cancerous growths which often healed spontaneously: others healed up in the centre, leaving the periphery as a source of infection.

Epilepsy and the Röntgen Rays.

Schuller reopened the discussion on the positive results of diagnosing epilepsy by means of the Röntgen rays, which he considered quite possible. Changes in both the soft and bony tissues could be observed. He divided epilepsy into four groups:—(1) Traumatic fissures, impressions and defects; (2) circumscribed or diffuse hyperostosis and osteoporosis, particularly that arising from syphilis; (3) asymmetry of cranium, both in contour and thickness; and (4) tumours or other processes producing increased pressure. The more recent additions to the diagnosis are an abnormal branching and serpentine movement of the arteria meningæ, and an excessive dilatation of the venæ diploëticæ, the latter having many variations, but distinct from the normal, and which is a guide to surgical interference, as these dilated vessels are difficult to check after being opened. All these changes appear in inter-cranial pressure, as they are always associated with tumours in the cerebrum. From the commencement of these changes the venæ diploëticæ appear to be the first vessels that are affected, and hence their diagnostic value in epilepsy.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Carnegie Trust.—The details of the second quinquennial scheme for the allocation of grants in aid of University endowment, which have been awaited with considerable interest, have now been made public. Of the income (£50,000) available, the demands made by grants in aid of research, and by the upkeep of the College of Physicians' Laboratory, will tend to increase: the trustees, therefore, have limited the expenditure on endowments to £40,000—a sum of £200,000 spread over five years. The previous decision of the trustees not to alienate permanently any of the sources of the income available is adhered to, but a part of the grant to each University not exceeding £1,000 may be treated by the body receiving it as income, and applied provisionally to the maintenance of the lectureships for which the Carnegie trustees are gradually, year by year, building up endowments. Coming to the individual claims of the several centres, the library grant has proved universally beneficial, and it is proposed to continue it (£1,000) to each of the four Universities. In St. Andrews and Dundee a number of endowments have been received since the last quinquennial allocation, and the trustees propose to contribute £1,000 towards the endowment fund of the Botanic Garden, £10,000 to complete the engineering department, and £500 for the equipment of the pathological laboratories; £5,000 each is to be devoted to lectureships in geology, history, and economics, with an annual grant of £300 additional in each case. The University of Glasgow, besides its library grant, asks for £13,500 to clear off debt on the departments of physiology, materia medica, forensic medicine, and public health; these the trustees have sanctioned. Sums varying from £1,500 to £7,500 are allocated towards the endowment of a Chair of Mercantile Law, and lectureships in English, French, German and Bacteriology. On the principle laid down above, provisional assistance in the way of annual income will also be afforded to these lectureships. The Glasgow and West of Scotland Technical College, and the Agricultural College, also receive substantial help from the fund. Speaking of the claims of the extramural medical schools, the trustees do not think that the results of the last quinquennial method—viz., the payment of subsidies to the teachers towards salaries of assistants, justify the continuance of the experiment. Special cases of this kind will be dealt with under the endowment of research. Anderson's Medical College, Glasgow, therefore, gets only a renewal of its £500 for equipment. The University of Aberdeen's needs, as far as buildings are concerned, will be met by an annual grant of £1,000. Various law, educational, and language chairs and lectureships fall to be endowed at a cost of £25,000. The University of Edinburgh is granted £6,000 to complete the physics buildings, £1,200 for fireproof room and library, £2,000 for apparatus, and £300 for cataloguing the anatomical museum. An endowment fund of £20,000 for lectureships is also allocated, and £13,000 is set aside for the extension of the departments of physiology, natural history, and pathology. Of extra-mural institutions, the Heriot-Watt College receives £2,000, and the School of Medicine of the Royal Colleges £250 a year, and the Medical College for Women £250 a year. A summary of the grants shows that during the ensuing five years St. Andrews will receive £37,500; Glasgow, £35,500; Aberdeen, £43,000, and Edinburgh, £58,000.

BELFAST.

The University Bill.—During the past week many meetings have been held, and many opinions expressed, on Mr. Birrell's University Bill. The point which promises to give most difficulty as regards Belfast is the affiliation of Magee College, "the one weak point of the scheme," as it has been called by a high educational authority in England. The academic opinion of Belfast is opposed to any such affiliation, and foresees all sorts of wirepulling to get other institutions affiliated. On the other hand, those interested in Magee College want it to be a constituent part of the new University, and not merely affiliated. The Higher Education Committee of the Presbyterian Church is considering the matter, but has not yet made a public pronouncement upon it. A meeting of the professors and lecturers at Queen's College was held in the College last week, when the President gave an account of the Bill and explained some of its clauses and how they would affect the College. After a discussion a series of resolutions was passed unanimously. The first expressed extreme gratification that an earnest attempt is to be made to settle the Irish University question on a permanent basis. The second was "That we rejoice that the provisions of the Bill ensure that the proposed new University in Belfast shall stand upon the same broad non-sectarian and academic basis on which Queen's College, Belfast, has worked since its establishment; that the University shall be free from religious tests and from all ecclesiastical control; that it is to be a free and completely self-governing University; and that public bodies, benefactors, professors, graduates, secondary teachers, women and students will be represented on its governing body." The third resolution was, "That in our opinion the elevation of this College to University rank will not only add much to the dignity of Belfast, making it a University city, but will give a great impetus to higher education here and throughout Ulster; that it will stimulate both teachers and students to show themselves worthy of the higher status now proposed to be granted by the Legislature; that it will excite much greater public interest in the College, and attract an increasing amount of public support from local benefactors; and that it will largely stimulate literary and scientific research, and promote the diffusion of knowledge and culture throughout the North of Ireland." The fourth and last resolution ordered these resolutions to be sent to various quarters. These give clearly and briefly the grounds on which the Bill has been so well received among the friends of the College.

The Treatment of Cerebro-Spinal Meningitis.—At a meeting of the Public Health Committee last week, the physician to the fever hospitals, Dr. Gardner Robb, reported that the treatment of cerebro-spinal meningitis by Flexner's serum was giving great satisfaction. Since its introduction last autumn the death-rate has been reduced from 75 per cent. down to 30 per cent. There is no corresponding decrease in the death-rate of cases outside not treated with the serum, and there seems no room for doubt that the credit must be given entirely to the new remedy. There are at present 16 cases of the affection in question in the Purdysburn Fever Hospital.

LETTERS TO THE EDITOR.

THE REFERENDUM OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of The Medical Press and Circular.

Sir,—It is a pity to enter into a controversy regarding the results of the voting on the Referendum as long as there is a prospect of coming to some amicable compromise, but "Nil Desperandum's" letter cannot be allowed to go unchallenged He is an instance of the want of study of the question which is really responsible for the apparent apathy among the members, for he confuses the object of the Referendum, and speaks of it as intended to "bring about reforms," and therefore "marking an era in the history of the Association." When even the Referendum itself is misunderstood in this absurd fashion, how can your correspondent be expected to know much of a really complicated document like the draft charter? The Referendum, according to Sir Victor Horsley and the other "reformers," was an "unconstitutional" and "illegal" procedure, but, in the opinion of those who are as competent to judge, was a dignified and indignant protest against the attempt on the part of certain men in the Association to capture the control of its affairs, without any means of checking their policy, however extravagant it might become. There is no intention to charge the members with indifference or want of intelligence, but the fact remains that, from want of time and inexperience of the business affairs of the Association, the bulk of the members know very little of the details of the Charter. Beyond the vague and often-repeated assertion that it is to be made more actively useful to the profession, they are apparently ready to take things on trust on the authority of a great man like Sir Victor Horsley. So your correspondent implies, but I doubt whether that clever surgeon will thank him for the prominence which he gives him. Statesmen have been known to wreck their party, and it is not worthy of a great profession to pin their faith to any man's sleeve. If we were afflicted with a 'family circle arrangement" in the Council, we are in danger of a still more select and autocratic oligarchy in the future government of the Association. I make no attack on Sir Victor Horsley or any man individually, and believe them, as I hope they believe me, to be actuated by purely disinterested motives.

The framers of the draft Charter have given an enormous amount of time and labour to the task, and have produced a splendid piece of work, for which they deserve our heartiest gratitude. But they are not infallible, and they may be too sanguine and even rash in their policy. At all events, I claim the right of individual judgment, and every instinct of prudence and caution rises up against the proposal to turn the Association into a medical trades union and a political faction. I see imminent danger, in these schemes, of internal dissension and external conflict which will neither make its financial position secure or its professional status respected.

Let us take a glance at the figures of the voting, and see what can be gleaned from them.

In the first place, it will be found that the majority is confined to England and Wales alone, and to the more populous parts of it. Everywhere else the vote is hostile to the "reformers," as your correspondent styles them. In Scotland the majority is decisively against—namely, 65 per cent. to 35 per cent. In Ireland the voting is more equal, being 54 per cent. against and 46 per cent. in favour. But a surprise comes from the Colonial Divisions, in whose supposed interests and at whose urgent request the draft Charter is being hurried on. With strange ingratitude the Colonial Divisions have gone dead against the "reformers," seven out of the ten which met being overwhelmingly hostile. No less than 70 per cent. of the votes cast were against the minutes. It will not do to waive aside in the airy fashion your optimistic correspondent affects to do the fact that the members of the Association are supremely indifferent to its business affairs. It is no sense of security in the profound wisdom of this or that leader that can account for such lamentable want of interest. Gallant little Wales came up to the scratch in splendid fashion by 8 out of 9 Divisions holding a meeting, and about 19 per cent. of the members attending (who belonged to these Divisions). Scotland comes next with 18 meetings out of a possible 22, and a voting strength of 13.8 per cent. England had 118 out of a possible 146, and an attendance of 12.5 at the meetings. Ireland showed very badly in the matter of meetings—viz., 5 out of a possible 14; but the attendance was not so bad—viz., 17.8. The Colonies are nearly as bad as Ireland, with 10 out of 32 possible meetings, and an attendance of only 8.6 of members. How are the abstention of members and the failure of Divisions to be accounted for? Meetings held for scientific purposes are not neglected in this fashion. Purely business matters have no attractions for our busy men, and they cannot afford the time to attend. Besides, the draft Charter is a hard document to grasp. Even the men who did attend had perforce to take their opinions from those who professed to understand it, for there was an extraordinary absence of individuality in the voting. In no fewer than 76 Divisions the voting was unanimous on one side or the other, and in 19 more was very nearly so. In only 23 Divisions was there anything like a healthy difference of opinion. This accounts largely for the result of the voting, for the "reformers" have a larger following in the representative meeting than their opponents, and big battalions tell. The delegates were exhorted to support their party, and the Divisions called upon to give a vote of confidence in their favour.

The voting has not been on the merits of the Charter at all, but a trial of strength between two parties, the smaller of which has been defeated. Let the victors beware how they act, for the real struggle is yet to come, and the rupture of the Association will be the result of any forcing tactics.

I am, Sir, yours truly,

"Festina Lente."

Edinburgh, April 8th, 1908.

THE QUESTION OF FEES.

To the Editor of The Medical Press and Circular.

Sir,—To the discussion of this important question, broached by a correspondent in your valuable paper of this week, I will, if you please, make a contribution. I assume that outside quacks, unqualified or fraudulent pretenders, are not included, and that we are considering only the ethics of remuneration among honourable professional men. Of course, there are quacks within the profession, but I believe they form a very small minority. And by a quack I mean a man who does not give the very first place to consideration of the welfare of his patient, but puts more or less in the foreground the thought of how much money he can extract from him. Men of this type are the subjects of moral obliquity approaching more or less, or even reaching, criminality; and, I repeat, I do not believe there can be many such among the members of our profession. It is, however, one thing to adopt the methods of a cynical, unscrupulous, and sordid money-grabber, and quite another thing to demand the fullest payment for devoted professional services. Then, next, what is a specialist? A specialist is one who, by knowledge, talents and accomplishments, has made himself conspicuously skilful in one or other department of medicine or surgery. What shall be the scale of remuneration for the real specialist, or, indeed, for any particular practitioner for whose services there may be more than the average demand—and it is only in these latter circumstances that he can, as a rule, obtain fees higher than the average—must surely be left for each individual practitioner to determine for himself. I would further urge that, assuming the specialist's skill to be of consummate excellence, no fee within the means of a patient, especially of a wealthy patient, can be considered exorbitant. All that the practitioner is called upon in fairness to do, is to inform his clients beforehand what are his fees, and particularly to leave no doubt when an unusually large fee will be called for. With this proviso it is certainly to the advantage of the profession, and in no way hurtful to the public interests, when a specialist demands the highest possible pecuniary reward for his services. He knows very well that there are a large number of men in the profession quite as able as he to deal with the ordinary cases he may reject, whilst by his rejection, by restricting his services to the few able to pay his high fees, he really helps to raise the scale of remuneration of all his brethren, who, although they may be less popular, are not much less skilful or deserving than he himself. Surely it must be for the advantage of the profession if the scale of pay for the most distinguished members is kept at the highest level. The world takes the profession at its own "price," and if there are more "five guinea men" at the top, there are likely to be fewer "eighteen-penny (including medicine) men" at the bottom. Much as I should like to append my name, there seem reasons, which I am sure you and your readers will appreciate, which compel me to withhold it, and to sign myself,

Yours truly,

A Specialist.

Cavendish Square, April 8th, 1908.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Conveyance of Whooping-Cough to Animals.—Macewen publishes (*British Medical Journal*, January 11th, 1908) the report of an experiment on the transference of whooping-cough to a cat. A healthy animal was chosen, and, being placed in confinement, was fed on sputum and vomit from patients suffering from uncomplicated whooping-cough, the material being mixed with milk. This feeding was maintained for seven days, and then the cat was fed with ordinary milk. A fortnight later the cat began to show signs of sickness, and at the end of a month it had developed a choky cough, which was always followed by vomiting. A little later the cough became spasmodic, and was accompanied by a definite whoop. During the spasms the animal became greatly distressed, and clung to the floor of its cage with its claws. The conclusion is justified that the infective material of whooping-cough exists in the sputum or vomit, or both. It is also suggested as possible that cats may act as agents for the distribution of the infection. R.

Pathogenesis of Acute Pancreatitis.—Williams and Busch (*Journal of Medical Research*, October, 1907) make suggestions, borne out by experiments on animals, as to the pathogenesis of acute pancreatitis. Starting from the observed association of acute pancreatitis with gall-stones, they suggest that some cases of pancreatitis may be due to regurgitation of duodenal contents into the diverticulum of Vater, the way having been opened by the passage of gall-stones. Attempts were made on the human cadaver to force the duodenal contents into the diverticulum of Vater, but without success, except in one subject out of nine. In this case the bile passages were dilated, the gall-bladder contained gall-stones, and a gall-stone was lodged in the cystic duct. In three animals out of ten, the introduction of duodenal contents to the pancreatic duct by injection produced pancreatitis, and in three others fat-necrosis. In several animals attempts were made to enlarge the diverticulum of Vater by forcing glass beads into it, with the result that more than half the animals experimented on developed fat-necrosis or pancreatitis. The authors further suggest that duodenal contents introduced to the pancreas produce pancreatitis by auto-digestion, as the necrotic pancreatic tissue seen in cases of acute hæmorrhagic and gangrenous pancreatitis closely resembles pancreatic tissue that has undergone auto-digestion. R.

Cancerous Growths.—Whipham publishes (*Journal of Pathology and Bacteriology*, January, 1908) a study of some 650 cases of cancerous growths which came under observation at St. George's Hospital in the course of seven and a-half years. 496 of the cases were carcinoma, 130 sarcoma, and 24 endothelioma. 268, or 44.3 per cent., of those affected were males; 362, or 55.7 per cent., females. This difference was due to the greater liability of the breasts and generative organs to be affected in women than in men. On the other hand, the alimentary tract was more frequently attacked in males—143 cases, as compared with 42. In 34 cases, or 5.2 per cent., there was a history of malignant disease in the family, and it is curious that in 28 of these the persons affected in one family were of the same sex in each case. In three instances cancer occurred in married couples. Two instances of cancer of the breast in the wife were associated with cancer of the liver and of the œsophagus in their respective husbands, while in the third instance the wife suffered from cancer of the tongue and the husband from cancer of the pancreas. An exciting cause was assigned in 145 cases, or 22.3 per cent., as follows: previous injury, 6.9 per cent.; irritation, inflammation, or ulcer, 10.1 per cent.; pre-existing tumour, 5.2 per cent. No cases of carcinoma were encountered under the age of 20, and only 2.6 per cent. under 30; the highest incidence, 30.2 per cent., was between the ages of 40 and 49, though the incidence in the following decade was very little less—29.6 per cent. Of sarcoma, 9.2 per cent. of the cases occurred under 20, the highest incidence, 23.9 per cent., being between 30 and 40. Of endothelioma, 4.1 per cent. occurred under 20, the highest incidence, 41.7 per cent., being between 50 and 60. It appears, therefore, that carcinomata and endotheliomata agree in reaching their maximum late in life. Dissemination of the primary growth occurred in 58 per cent. of the carcinomata, 36.1 per cent. of the sarcomata, and 50 per cent. of the endotheliomata. (This estimate must be far from complete, since many of the patients were alive at the time of writing, and many metastases are only discovered on the post-mortem table.) The author discusses the various theories of the mode of spread of cancer, and he believes that in many of his cases of carcinoma of the alimentary, respiratory, and genital tracts (22 in all) dissemination took place by direct implantation. He adds a complete tabular record of the cases, giving the primary seat, the nature of the growth, the occurrence of metastases, the results of treatment, and other particulars. R.

A Modified Opsonic Technique.—Veitch describes (*Journal of Pathology and Bacteriology*, January, 1908) a modified method of estimating the phagocytic activity of the blood. The essential difference from Wright's method is that he omits the washing and preparation of leucocytes. The materials used are two volumes of the patient's or control blood, two of 1.5 per cent. sodium citrate solution, and one of a suspension of the bacteria in 1.25 per cent. salt solution. These ingredients are measured and mixed in the usual way, incubated for 15 minutes, a film stained and examined. The author states that quite sufficient leucocytes are present. If immediate incubation is impossible, then only the blood and the citrate solution should be mixed at first, the bacterial emulsion being added immediately before incubation. The author has in several cases compared the results obtained by this method with those obtained at the same time by Wright's method, and the differences are negligible. The method certainly has many advantages in its ease of application. R.

Treatment of Actinomycosis by Vaccines.—Wynn (*British Medical Journal*, March 7th, 1908) publishes the report of a successful case of what is, we think, the first attempt to treat actinomycosis by a vaccine. The patient had actinomycosis of the lung and liver, which necessitated the removal of part of a rib in an attempt at drainage. A copious discharge of pus, containing the ray fungus, persisted, and the temperature continued pyrexial. Agar-cultures of less than 48 hours were adopted for the preparation of the vaccine. The growth was scraped off, sterilised, and dried for an hour at 60° C. It was then ground in an agate mortar with normal saline solution containing 10 per cent. glycerine. One-thousandth part of a milligram of the solid substance was used as a dose. The first injection was given three weeks after the operation, and resulted in an immediate improvement in the patient's condition, the pulse-rate and temperature settling to normal. In all six inoculations were given at intervals of ten days to a fortnight, the results being marked in every case. At the end of the treatment the patient was apparently in excellent health, and though a cavity remained in the lung, there was no sputum, and the breath was not offensive. Ten months later there had been no falling back. Attempts were made to keep opsonic observations, and the writer is confident that the index was raised by the treatment. R.

Papillary Cystadenoma of the Breast.—Greenough and Seminous (*Publications of the Massachusetts General Hospital*, June, 1907) publish a description of the above tumour, based on a study of 20 cases. The same tumour has been described under various names, of which some of the best known are adenoma, duct papilloma, and duct cancer. According to the writers, it is not an uncommon growth, and it involves, as a rule, the large ducts of the breast, and is therefore situated near the nipple. The typical structure is one or more cysts filled with papillary ingrowths springing from the wall. The papillary growths have a branching connective tissue stalk, containing blood-vessels, and supporting a luxuriant growth of epithelium in the form of villous projections and gland-like interlacing tubules. The epithelium shows no tendency to infiltrate the surrounding tissues. It varies in its appearance in different specimens, and even in different parts of the same specimen. The lining of the larger cysts is commonly flattened and of several layers, whereas that on the smaller cysts and on the papillary tufts is more columnar in shape. The degree of proliferation of epithelium varies greatly. The rate of growth is slow, but of the twenty cases three showed signs of adeno-carcinoma. No definite cause can be assigned, the tumour being independent of trauma and lactation, and occurring at all ages. One of the patients was a male. R.

The Cell-Islets of Langerhans.—Vincent and Thompson (*Biophysikal. Centralbl.*, February, 1908, p. 319) have examined the pancreas in several mammals, in birds, fish and amphibia, and report accurate details of their work. They have arrived at one important conclusion regarding the cell-islets of Langerhans, and that is that there is a constant upbuilding of the gland parenchyma out of these islets, and a subsequent breaking down of the parenchyma during gland activity. In the condition of inanition of the gland brought about after exhaustion of secretory power by the injection of secretin, there is a great increase in the number of the islands, followed later on, as the gland recovers, by an increasing preponderance of the ordinary gland acini. The authors, in consequence, conclude that the islets cannot be regarded as a tissue *sui generis*. As regards their function, no opinion is expressed. M.

Ranula of Unusual Size.—Dr. Bale reports a case of a patient in whom a ranula of very large size was present (*South African Med. Record*, March 10th, 1908, p. 68). The patient was a native girl, æt. 13, who came under notice complaining of a swelling in the neck which had been present for three years. The tumour occupied the right submaxillary region, and extended in a spindle-shaped form along the anterior margin of the right sterno-mastoid muscle down to the level of the cricoid cartilage. On opening the mouth a tumour was also found under the front of the tongue, and was readily proved to be in communication with the cervical swelling, inasmuch as pressure upon the one caused enlargement of the other. The cyst was eventually excised, and proved to be a large bi-lobed ranula containing glairy mucoid fluid of a reddish colour. M.

Primary Hæmangioma of Muscle.—Davis presents an important literary and clinical study of this subject, based upon one case of his own and five others that had been operated on in the Johns Hopkins surgical clinic (*Johns Hopkins Hospital Bulletin*, March, 1908, p. 74). He has been able to include in his review 153 cases in all—a number which shows that the condition cannot be regarded as extremely rare. His main conclusions are as follows:—Primary hæmangiomata of muscle are slowly growing tumours, usually congenital in origin. They occasionally follow trauma, and may occur in any striated muscle. Compressibility, change in size on raising or lowering the limb, and pain, are the three typical symptoms, although any one or all of them may be lacking. The skin over them is usually normal, and the tumours themselves are usually soft, but may be hard, smooth, or lobulated, movable or fixed, circumscribed or diffuse. They vary in size from a small nut to a child's head. There are two principal varieties—the simple, which is rare, and the cavernous, which is more common. On section the characteristic appearance of a blood-filled sponge, brownish-red in colour, is seen. Microscopically the typical picture is that of blood-filled spaces lined with endothelium, containing normal blood, and surrounded by walls of smooth muscle and connective tissue. Phleboliths are often present in the blood spaces, as well as in the dilated veins, and are thrombotic in origin. The only treatment of value is excision, which, if complete, is practically sure to cure the condition. M.

Polyserositis.—May reports a case of this interesting condition (*Ext. Centralbl. f. Inn. Med.*, April 4th, 1908, p. 343). The patient, a man, æt. 20, was admitted to hospital suffering from severe ascites. Nothing abnormal could be detected on examining the heart, and in consequence a diagnosis of tubercular peritonitis was arrived at. At the autopsy complete obliteration of the pericardial sac was found; the spleen was enlarged, with thickened capsule; the liver was reduced to one-half its normal size, was smooth and uniform, and had its serous covering enormously thickened. The general consistence of the liver also was increased. Neither the peritoneum nor the pleura was thickened. May considers the absence of pleural and peritoneal involvement should prevent one from considering this a true case of polyserositis, and is inclined to group it under the symptom complex described as a pericardial pseudo-liver-cirrhosis. M.

OBITUARY.

DR. ROBERT COWAN LEES, M.B., C.M.GLASG., F.F.P.S.

We regret to record the death of Dr. Robert Cowan Lees. Till quite recently he was discharging his usual professional duties, but he was prostrated by pneumonia, which culminated fatally early on April 3rd. He received his education in Glasgow, passing from school to the University, where he graduated in medicine in 1879. All through his professional career he was associated with Glasgow, and had many interests sincerely at heart. For some years he lectured on medicine in the Western Medical School. He was a frequent contributor to medical journals, and in 1885 he was elected a Fellow of the Faculty of Physicians and Surgeons. In the Volunteer movement he took an active part, attaining the rank of surgeon-major in the 1st Lanarkshire Rifle Volunteers. Apart from professional work, he found time to devote to public affairs. He was a Justice of the Peace, Chairman of the Park Ward Municipal Committee, and President of the College Division of the Conservative Association, succeeding in the latter office the late Professor Sir Thomas M'Call Anderson. Keenly alive to everything bearing upon his profession, he commanded the confidence of his patients, and his frank and generous temperament made him many loyal friends.

FRED J. MACPHAIL, L.S.A.

We regret to announce the death of Dr. Fred J. Macphail, medical officer at Winwick Asylum, Warrington, who died on April 6th. The deceased gentleman previous to his appointment at Winwick, was one of the best known Rugby footballers in the district, being a prominent member of the Liverpool Old Boys' Club. His father is the Rev. Dr. Macphail, who was pastor of Canning Street Presbyterian Church, Liverpool.

Medical News in Brief

Royal College of Surgeons of England.

At a quarterly meeting of the Council, held at the College last Thursday, the President and Vice-Presidents reported that, in pursuance of a resolution adopted by the Council at their last meeting, they had addressed the following letter to Sir Henry R. Swanzy, President of the Royal College of Surgeons in Ireland:—

The New Irish University Bill.—"At their meeting on March 12th the Council of this College had under consideration your letter calling attention to the proposed foundation of a new Irish University, and its probable effect upon the Royal College of Surgeons in Ireland; and we were desired by the Council to write and express to you the strong sense which they entertain as to the importance of maintaining in Ireland a Royal College of Surgeons, and the hope that in any Bill which is brought forward to establish a new Irish University, provision may be made to safeguard the interests of your College. The Royal College of Surgeons in Ireland, like its sister College in England, was founded with the object of promoting the study of surgery and regulating its practice for the benefit of the public, and we venture to think that the history and traditions of your College amply show that continuous effect has been given to this primary object of its foundation. We highly esteem the important services to surgical education rendered by your College through its school and examinations, and specially do we regard your Fellowship as of great value as a mark of surgical skill and knowledge; and we believe that in promoting the study of surgery, and maintaining a high standard of professional conduct among its practitioners, your College has been able to perform duties of great value to the State and public. We should, therefore, regard it as a misfortune, not only to the profession, but to the public, if legislation were introduced which should result in diminishing or impairing the functions now exercised by the Royal College of Surgeons in Ireland. The Council of this College sincerely trust that you may be successful in your appeal to His Majesty's Government, and that the Royal College of Surgeons in Ireland may be able to continue that career of usefulness which has won for it so much distinction in the past."

Primary Examinations for the Fellowship.—It was determined to inform the Deans of the Medical Faculties of the Universities of Leeds, Liverpool and Sheffield that the Council, having consulted the several medical schools in reference to the proposal to alter the dates of the primary examinations for the Fellowship, and having considered the various suggestions made, were of opinion that it is undesirable to make any change.

Mr. Arthur Keith was admitted as conservator of the museum. A vote of thanks was given to Mr. R. H. Burne for his services in carrying on the duties of conservator of the museum during the illness and since the death of Professor Stewart, and he was appointed Assistant Conservator. Mr. Burne has been anatomical assistant in the museum since 1892.

A vote of thanks was given to Mr. Edmund Owen for his services as visitor to the examinations of the Egyptian Medical School at Cairo. The Jacksonian Prize for the year 1907 was not awarded. The subject for the prize for the year 1909 will be, "The Treatment of Surgical Affections by Vaccines and Anti-Toxins." A report was received from Mr. J. Ward Cousins regarding the proceedings of the Central Midwives Board during the past year, and the thanks of the Council were given to him for his services as the representative of the College on the Board.

Mr. J. B. Dawson, M.B.Lond., having passed the required examinations and conformed to the by-laws, was admitted a Fellow of the College. Mr. T. J. Walker, Consulting Surgeon to the Peterborough Infirmary, and Mr. H. P. Keatinge, Director of the Egyptian Government Medical School at Cairo, were elected Fellows of the College as members of twenty years' standing. Messrs. K. D. Panton, Toronto University; R. K. Paterson, Kingston, Canada, and London Hospital; and G. C. E. Simpson, M.B., B.A., Cantab., were admitted members of the College.

The Senates of the Proposed New Irish Universities.—Forecast.

It is stated that the following will be nominated as members of the Senate of the proposed new University in Dublin:—Chancellor: Sir William Butler, K.C.B. Members of the Senate: The Most Rev. Dr. Walsh, Roman Catholic Archbishop of Dublin, and the Most Rev. Dr. Healy, Roman Catholic Archbishop of Tuam; Mr. J. S. McArdle, Dr. J. J. O'Carroll, and Dr. M. J. Cox. Among the seven Protestant members are Mr. Butcher, M.P., Dr. Douglas Hyde, and Mr. Stephen Gwynn, M.P.

In the case of Belfast the forecast is fuller, and is as follows:—Chancellor: The Earl of Shaftesbury. Pro-Chancellors: Sir Donald Currie, Sir Robert Hart. Vice-Chancellor: The President of the Queen's College. Crown Nominees: Right Honourable Robert Young, Mr. John Cooke (H.M.L., Londonderry), Dr. P. O'Connell. Staff Representatives: Professor Sir William Whitla, Professor M. F. Fitzgerald, Professor E. A. Letts, Professor T. Sinclair, Professor J. Park, and Professor S. Dill. Graduates' Representatives: Mr. Justice Dodd, Judge Shaw, Dr. J. Walton Browne (R.U.I. Senator), Professor M. Leitch (R.U.I. Senator), Professor Leebody (R.U.I. Senator), and Mr. R. T. Martin. Registrar: Professor Johnson Symington. Representatives of Benefactors: Sir Otto Jaffe, Mr. H. Musgrave, D.L.; Mr. F. Purser, F.T.C.D.; Dr. P. Redfern, Mr. R. Dodds, M.A. Local Representatives: The Lord Mayor (Sir Robert Anderson), President Chamber of Commerce (Sir Charles Brett), Chairman Royal Victoria Hospital (Sir William Crawford). Secondary School Representatives: Mr. R. M. Jones, M.A.; Principal Royal Academical Institution (probable).

The Late Dr. Connolly Norman.

A meeting was held on Thursday last in the Royal College of Physicians, Dublin, to consider the question of erecting a suitable memorial to the memory of the late Dr. Connolly Norman. The President of the College presided. Among those present were Sir Henry Swanzy, President of the College of Surgeons, Dr. Little, Sir Francis Cruise, Sir Thornley Stoker, Dr. Magee Finny, Dr. W. Dawson, Dr. Maxwell, Dr. J. O'Conor Donelan, Dr. Baker, Dr. Fleury, Dr. Cullinan, Rev. M. Taylor, J. R. O'Connell, Esq., LL.D., and Dr. Carroll. Dr. Little and Sir Francis Cruise expressed sympathy with the object of the meeting. Sir Henry Swanzy paid tribute to the memory of the late Dr. Connolly Norman. After some discussion an executive committee was appointed. Dr. Dawson and J. R. O'Connell, Esq., LL.D., were appointed treasurers, and Dr. Donelan and Dr. Fleury secretaries. The meeting then adjourned for a fortnight.

PASS LISTS.

Royal College of Surgeons in Ireland—Election of Examiners.

A meeting will be held on Tuesday, May 5th, at 4.30 p.m., to elect examiners.

"Graduates of any University which may be from time to time recognised by the College shall be eligible for election as Examiners in the subjects of General Education. All the other Examiners shall be Fellows or Licentiates of the College, or Professors or Lecturers in any School of Medicine recognised by the College."

Candidates are requested to lodge their applications in writing with the Registrar, at the College, on or before Tuesday, April 28th, at 10 a.m.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

The following candidates have passed the first Professional Examination, April, 1908:—T. D. Condell, N. S. Deane, T. Dillon, W. H. Johnston, J. Kearney, J. E. J. Roche Kelly, W. Lumley, F. P. McDermott, L. O'Donovan, P. Walsh, V. White.

The offices of the Committee of Management will be closed from April 16th to 20th, 1908 (inclusive).

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

VIRIDIS.—The question of the origin of the green colouring of oysters has agitated people for quite a century, but MM. Puysegur and Bornet, by careful experiments, showed in 1877 that it was caused by the blue diatomea, which served as food for the oysters. Oysters purchased at Arcachon or in Brittany are placed in ponds dug out in the clay. There the oysters either "work" or "sulk." An oyster "at work" opens and closes its valves from time to time, sets in movement numberless vibratile filaments, thus causing a whirlpool, which drags into its stomach the water with a multitude of small particles and Diatoms. At the same time as it becomes green the oyster fattens, its flesh becomes more delicate. The fattening process is more or less slow; it occupies at least a season. The oysters that "sulk" remain closed, because some unfavourable circumstance disturbs them. If their situation improves, they get to "work"; if not, they die.

LESSEE.—You have to pay the house duty yourself, but the land lord is bound to allow you to deduct it from the next payment of rent.

OBSTETRICS.—The matter of midwifery instruction is a very serious question which will have to be settled definitely before long. We fail to agree about present-day teaching. We may deal with the matter shortly.

HUJUS.—We should be very glad to know more of the circumstances. Could you send us a cutting from the local press? We will be most happy to take your part if we find the circumstances warrant our doing so.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, APRIL 15TH.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m.: Mr. J. Strachan: On Dendritic Growths of Copper Oxide in Paper. Mr. F. Enock: Nature's Protection of Insect Life (illustrated by lantern slides in three-colour photography.)

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (20, Hanover Square, W.).—8.30 p.m.: Adjourned Discussion on Dr. Prout's paper on the Rôle of Filaria in the Production of Disease. Dr. Prout: On an Unusual Cause of Dysenteric Diarrhœa in the Tropics. Dr. T. P. Macdonald (North Queensland): Tropical Lands and White Races.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m.: Mr. T. P. Legg: Clinique (Surgical.)

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Cliniques: Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks). 3 p.m.: Demonstration on Fevers (at the North-Eastern Fever Hospital, St. Ann's Road, N.): Dr. F. Thomson.

Appointments.

BAIRD, HARVEY, M.D., Ch.B.Edin., Assistant Medical Officer at the Cardiff Mental Hospital.

CALDWELL, M. F., M.B., B.Ch.Irel., Junior Assistant Medical Officer at the Cardiff Mental Hospital.

DOWNES, HAROLD, M.B., L.R.C.P.Edin., Medical Superintendent to Benenden Sanatorium.

FORDE, T. A. MUNRO, M.R.C.S., L.R.C.P.Lond., Honorary Senior Surgeon to the Royal Hospital, Portsmouth.

GRIFFITHS, EVAN JOHN, M.B., Ch.B.Edin., Medical Officer for the Inspection of School Children by the Pontypridd Education Committee.

HEBBLETHWAITE, A. G., M.R.C.S., L.R.C.P.Lond., Honorary Physician to the Keighley Victoria Hospital.

LAWRIE, D., M.B., M.S.Glasg., Assistant Medical Inspector of Schools for the Glastonbury District of Somerset.

NASH, J. T. C., M.D., C.M.Edin., D.P.H.Cantab., Medical Officer of Health to the Norfolk County Council.

PAGE, H. M., F.R.C.S.Eng., Honorary Anæsthetist to Guy's Hospital.

STEVENSON, T. H. C., M.D. State Med. Lond., Chief Medical Inspector of Schools for Somerset.

Vacancies.

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, apartments, attendance, and washing. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

Borough of Southend-on-Sea.—Medical Officer of Health. Salary, £550 per annum. Applications to William H. Snow, Town Clerk, Southend-on-Sea.

Camberwell House Asylum, London, S.E.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, and laundry. Applications to the Medical Superintendent.

County Borough of Southampton.—Assistant Medical Officer of Health. Salary, £150 per annum, with residence, board, and washing. Applications to the Town Clerk, Town Clerk's Office, Municipal Offices, Southampton.

Borough of Bootle.—Hospital for Infectious Diseases.—Resident Medical Officer. Salary, £120 per annum, with board, washing, and apartments at the Hospital. Applications to the Chairman of the Health Committee, Town Hall, Bootle.

Births.

FOX.—On April 7th, at 63, Grosvenor Street, London, the wife of Wilfrid Fox, M.D.—a son.

HAYWARD.—On April 9th. at 23, The Grange, Wimbledon, the wife of John Arthur Hayward, M.D., F.R.C.S.—a daughter.

HILLYER.—On April 11th, at Heathcote, East Grinstead, the wife of W. Henry Hillyer, M.D., D.P.H.,—a son.

NITCH.—On April 10th, at 69 Harley Street, London, the wife of Cyril A. R. Nitch, M.S., F.R.C.S.—a son.

PAVITT.—On April 9th, at 19, Crediton Road, Hampstead, the wife of Percy G. Pavitt, M.R.C.S., L.R.C.P.Lond., L.D.S., —son.

Marriages.

GRINDROD—CARR.—On April 13th, at St. Pancras Church, London, John Townly Grindrod, M.A., Cantab., of Blackpool (formerly of Liverpool), to May Louise Ashdown, only daughter of Thomas Carr, M.D., and Mrs. Carr, of Blackpool.

JAMISON—HEYWORTH.—On April 9th, at All Saints', Ennismore Gardens, London, Reginald Jamison, F.R.C.S., of 80, New Cavendish Street, London, son of the late Arthur Jamison, M.D., to Eanswythe, daughter of the late Colonel Lawrence Heyworth, and of Mrs. Heyworth, of Colne Priory, Earls Colne.

MAXWELL—CLARK.—On April 7th, at St. Mary Abbots, Kensington, Herbert Bowen Maxwell, M.R.C.S., L.R.C.P., to Elsie Constable Clark, younger daughter of the late Andrew Clark, Esq., of Glasgow, and Mrs. Clark, of 67 Castletown Road, West Kensington.

OXENDALE—PALMER.—On April 9th, at St. George's Church, Tufnell Park, London, by the Rev. G. E. Asker, M.A., Thomas Trevor Ranson Oxendale, elder son of the late Thomas Lowson Oxendale, M.D., of Heighington, Darlington, to Esther Caroline Palmer, eldest daughter of James Buckland Palmer, of 194, Brecknock Road, London.

Deaths.

BROWNE.—On April 9th, of heart failure after operation, Oswald Auchinleck Browne, M.D., F.R.C.S., of 7, Upper Wimpole Street, London.

GARTH.—On April 10th, in Calcutta, Henry Charles Garth, M.B., Edin. fourth son of the late Right Honble. Sir R. Garth, aged 47 years. (By cable.)

The Distinctive Excellence of

PARKE, DAVIS & CO.'S

HYPODERMIC TABLETS

They are Uniformly Active. Parke, Davis & Co. make it an invariable rule to standardise every drug that enters into these tablets. It is everywhere recognised that this affords the only accurate means for treating disease.

The Dosage is Accurate. P., D. & Co. Hypodermic Tablets are made by a process which ensures absolute accuracy of dosage and the exclusion of impurities and germ infection.

They Dissolve Instantly. P., D. & Co. Hypodermic Tablets, being moulded, immediately form a clear solution with water, whereas many compressed tablets merely disintegrate, or dissolve with great difficulty.

Prices are Right. Besides these invaluable qualities, the prices are highly advantageous. Please note that there are **25** P., D. & Co. Hypodermic Tablets in each tube.

All-round Merits Appreciated. For therapeutic activity, accuracy, solubility, and relative economy, P., D. & Co. Hypodermic Tablets are preferred by all discerning users.

ALL LEADING PHARMACISTS HOLD THEM IN STOCK.

Our new brochure, "HYPODERMIC MEDICATION" (pp. 32 8vo.), containing a full list of P., D. & Co. Hypodermic Tablets and Pocket Cases, will be sent to any medical man on request.

PARKE, DAVIS & CO., LONDON.

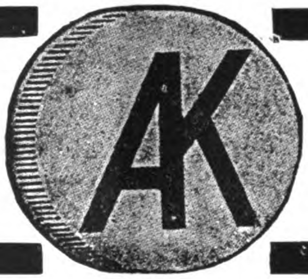
Antikamnia

ANALGESIC. ANTIPYRETIC. ANODYNE.

In the administration of Remedies to relieve **PAIN**, the element of exhilaration should be considered, as many produce such delightful sensations as to make them dangerous to use.

Such is not the case with Antikamnia Tablets.

They are simply pain relievers—not stimulants—not intoxicants. Their use is not followed by depression of the heart.



In cases of **Acute Neuralgia,** tested with a view of determining the analgesic properties of Antikamnia, it has been found to exceed any of its predecessors in rapidity and certainty of the relief given. **Neuralgia, Myalgia, Hemicrania,** and all forms of **Headache, Menstrual Pain,** &c., yield to its influence in a remarkably short time, and in no instance has any evil after-effect developed. The adult dose is one or two tablets every one, two, or three hours. To be repeated as indicated. All genuine tablets bear the AK monogram.

Strongly Recommended.

ANTIKAMNIA & HEROIN TABLETS

(5 gr. Antikamnia, 1.12 gr. Heroin Hydrochlor.)

A Respiratory Stimulant, Sedative, Expectorant and Analgesic.

Heroin Hydrochloride is indicated in Coughs of all kinds, in Dyspnœa, and in Catarrhal Inflammations of the Respiratory Mucous Membrane, and in all cases in which morphine is contra-indicated; while **Antikamnia** furnishes the Analgesic, Antipyretic, and Anodyne effect which is so soothing and comforting to patients.

ANTIKAMNIA Tablets
ANTIKAMNIA & HEROIN 5gr. Tablets } Supplied in 1-oz. packages to the medical profession.

Of all Leading Drug Houses and

THE ANTIKAMNIA CHEMICAL COMPANY,
46 Holborn Viaduct, London.

TRADE **'ALAXA'** MARK

AN AROMATIC LIQUEUR
OF CASCARA SAGRADA

'ALAXA' presents a *fluid* cascara of the same high therapeutic standard as 'TABLOID' CASCARA.

'ALAXA' is the result of specialised study and research, and embodies the nearest approach to the isolation of the pure active principle of Cascara Sagrada yet obtained.

Its laxative action is supplemented by stomachic and carminative constituents.

'ALAXA' is so palatable that it may be given as an aperient *apéritif* or a laxative *liqueur.*

Careful clinical tests have confirmed its certainty of action and its superiority to bitterless extracts treated with excess of alkali, and rendered comparatively inactive in consequence.

ALAXA
ALAXA
AN AROMATIC LIQUEUR OF CASCARA SAGRADA
BURROUGHS WELLCOME & CO

One fluid drachm contains the equivalent of twenty-four minims of Liquid Extract of Cascara Sagrada, B.P.

SPECIAL NOTE

Cordials and Elixirs are so loaded with syrup and flavouring matter that a large dose is required.

The full dose of 'ALAXA' is 2 fluid drachms.

Supplied to the medical profession, in 4-oz. bottles, at 2/- per bottle

BURROUGHS WELLCOME & CO., LONDON (ENG.)

The "Lancet" on Cocoa.

Of the beverages in common use (Tea, Coffee & Cocoa), Cocoa is the best, because—

1. It is not a mere stimulant; it is also a true food.
2. Its stimulant value is similar to that of beef tea, and its nutritive value bears comparison with that of milk.

Of test cocoas bought in the open market, Van Houten's proved to be the best; because—

1. It is the most finely sub-divided, leaving no sediment in the cup.
2. It is the most soluble and perfectly miscible, consequently the most economical in use.
3. It is the most readily digested in the gastric juices.
4. It contains the maximum proportion of the proximate principles of food.

These facts, **elicited by unbiassed scientific investigation (vide "Lancet," Jan. 7th and Feb. 4th, 1905)** place Van Houten's Cocoa in the front rank of modern dietetic preparations.

It is quickly absorbed in the stomach, leaving no undigested irritant residue, and is therefore pre-eminently suitable for invalids.

VAN HOUTEN'S COCOA.

THE MEDICAL PRESS AND CIRCULAR.

VOL. CXXXVI. WEDNESDAY, APRIL 22, 1908. No. 17.

NOTES AND COMMENTS.

Advance Australia. THE proprietors of proprietary medicines have been stirred to frantic efforts to stay what is described as the "fanatical" legislation proposed by the Commonwealth Government of Australia. No one who has read the report of the Commission appointed to inquire into the trade is in the least surprised that the Government is prepared to take strong measures to prevent the fraudulent business which masquerades under the pretence of trade secrets, and we are glad to see that it seems inclined to push its proposals through without sacrificing the principles at stake. We confess to having but little sympathy with trade secrets in connection with means for the relieving of human misery or the saving of human life, even in respect of legitimate preparations. Drug manufacture should be conducted on scientific chemical principles, and there should be no secrets in scientific work. It is one thing that medical men should be able to insist on patients having the preparations of some firm in whose products they have confidence, and quite another that the price of a certain drug should be enhanced because it is manufactured on a secret principle which is kept private for the benefit of some individual. There are, fortunately, plenty of respectable, high-class firms which are content to take their stand on the purity and quality of their goods, without claiming any secret for themselves.

Trade Secrets. THE trade secret myth under which the quack medicine vendor sells his common-place mixtures and pills is one that is entitled to no respect from honest men, and we hope all the importunities of the trade will not affect the decision of the Commonwealth Ministers. The basic principle of the proposed legislation is the disclosure of the contents of quack medicines on the label, and the trade recognise this as the death-blow of their business. So far, the Minister of Customs, on whom falls the responsibility of shaping the Bill, is only prepared to recommend as an exemption those goods which the Governor-General in Council is satisfied would, by disclosure, suffer in a legitimate way, without protecting the public. This exception we think unfortunate, as it would devolve entirely on the administrators of the Act as to what preparation would and would not be included, and knowing something of the pressure which powerful interests can bring to bear on officials, we cannot help thinking the Government would best protect their population by making no exceptions. The interesting lesson these facts suggest is that the evil of the quack medicine trade is recognised in our great dependency and is being earnestly grappled with, in the face of the Press and all other interests, while in England the question is not even a live one with our Ministry. The conduct of the Licensing Bill through the House of Commons would be child's play compared with the passage of a Bill to do away with the swindling preparations foisted on the poor by means of advertisements in newspapers and magazines of all descriptions.

A Nerve Specialist. IN the High Court last week an action was brought by a gentleman to recover some £500 lent to a lady on the security of her income, which was derived from her profession of a "nerve specialist." Evidence given by a solicitor who negotiated the business that the lady told him her income from this source was £2,000 a year, £800 of which was net. Various charges and counter-charges were made, but eventually the jury found for the plaintiff. It is rather disappointing that the facts as to this practice of "nerve specialism" did not come out at the trial, or at any rate were not reported, for it is wonderful to reflect how this large income was made so steadily and so safely as to be regarded as security for money advanced. What sort of treatment does this type of "nerve specialism" involve? And how are clients obtained? It might help some struggling medical brethren to know, as the ordinary practice of the profession seldom shows such figures. The case, at any rate, suggests the inadvisability of the growing practice of medical men calling themselves "specialists," as the term has no legal significance, and can be appropriated by "nerve specialists," "canine specialists," *et hoc genus omne*, with impunity.

Kissing not by Favour. THE London County Council, in their wisdom, have issued a notice to the effect that "Kiss-in-the-ring," and other kissing games, are to be discontinued in the Council Schools and in the non-provided schools for which they are responsible. "On medical grounds the practice is considered undesirable," runs the order. At the risk of being considered old-fashioned we cannot restrain a sigh that a pastime so popular and so exhilarating should be relegated to the limbo of unhygienic things, and we feel almost inclined to beg the authorities to consider the restrictions which a strictly hygienic life would entail. Is it not possible that the banishment of poetry and display of the affections from the narrow round of the London urchin's existence, might not conduce to a state of materialism and ill-mannerism even more perilous to the State than a putative risk of infection? The too-aseptic child might, it seems to us, become as sterile to the growth of kindly sentiments and light heartedness as to the growth of noxious microbes, and we know that in banishing the baleful bacteria we also banish the friendly ones. At any rate, we shall watch with attention the infectious disease returns for London, and if it does not show a fall as the result of the new Order in Council, we shall be inclined to put in a plea for the re-establishment of those pleasant amenities which combine a slight risk of infection with the cultivation of that inestimable possession, the *joie de vivre*. After all, as Stevenson has said, the first duty of man is to be happy.

Quare Fremuerunt.

The reasons for drinking were discussed last week in a thoughtful paper by Dr. Stanley Atkinson, read before the Society for the Study of Inebriety, and the author ended his arguments by a quotation from Dr. Mott, to the effect that the causes of drinking are infinitely varied, being intimately bound up within the temper and character of man. Indeed, the list of causes seems to cover each possible state of consciousness and its precise antithesis, fear, courage, sympathy, aversion, joy, sorrow, love, hatred, and so on. The list fully bore out another very apt citation from a medical author of 1700, Dr. Henry Aldridge, to the effect that

"There are five reasons why men drink;
Good wine, a friend, and being dry,
Or lest you should be by-and-by,
Or any other reason why."

Two hundred years of thinking and drinking do not, therefore, seem to have advanced knowledge of the causation of drunkenness very far. The reason why men drink apparently is because they like to, and the argument would therefore seem to be that either the opportunities for indulging their taste should be limited, or that they should be taught to like not to. The discouraging result of most attempts at temperance legislation hitherto is due, we fear, to the fact that the poor man does not care to be "robbed of his beer," and that he will continue in that dislike till the desire for beer is removed by the substitution of better leanings.

LEADING ARTICLES.

THE PRESENT POSITION OF THE MEDICAL PRACTITIONER.

The position of the average medical practitioner with regard to the struggle for existence appears to be at present in a somewhat acute stage of precariousness. There is reason to believe that he shares to a great extent in a commercial depression that is affecting most ranks of society. Yet even in times of national prosperity it is more than doubtful that he obtains the amount of emolument from his life-work to which his professional skill and services are entitled. A perusal of some of the earlier volumes of medical journalism will show that the grievance is no new one, although it probably has reached its acme at the commencement of the twentieth century. There can be little doubt that, in spite of prizes here and there, the average medical practitioner does not obtain an income adequate to recompense him for the years of careful study and of hard, conscientious, and highly technical and responsible work which come as a part of his vocation. It has often been urged that the chief reason for the inadequacy of income is the overcrowding of the profession, but that view is hardly borne out by the facts of the case. If we may accept some recently published statistics, there are in the United Kingdom some 34,907 qualified men and women to about 43,000,000 population. This would give one medical practitioner to about every 1,230 of the population of the British islands. Further statistics show that the average for the whole of Europe is one medical man to every 2,033. These figures may for present purposes be received as approximately correct. They do not represent an excessively undue proportion of medical attendants when we take into account the large number of medical men engaged in consulting and special practice, and another large section whose services are required by the State for army, navy, poor-law, and other public services. Viewed in this way, there appears not to be an undue number of medical men in the United Kingdom; and the restricted nature of their incomes appears to be due, not to the fact of competition in their own ranks as of competition from without. The State, which demands prolonged and careful training and stringent examination tests before it will grant the legal medical qualification, yet takes no steps to protect the community from the evils of quacks and quackery. The result is that all kinds of charlatanry are rampant to an extent that has never been hitherto equalled in the annals of civilisation. There needs little argument to show that all this means the diversion into alien channels of what would otherwise be a legitimate source of income for qualified medical men. Nor is there any need for the medical profession to be shy of admitting this phase of the problem of their diminished and diminishing competency. Finance is a material and inevitable condition of existence common to all professions, learned or otherwise; and, because the work performed by a medical man is essentially of a humane character, there is no obligation on his side to abandon the reciprocal due whereby his existence is maintained. There are various quarters from which comes a faint promise of relief. Thus in recent years great medical organisations have sprung into existence, and in some of them various extra-mural and intra-mural problems have become the subject of serious discussion. Even the General Medical Council has shown some slight awakening to the isolation of their position as regards the vital wants and aspirations of the medical profession. To increase the direct representation upon the Council, to enlarge its powers so as to render it a body capable of defending the rights of medical practitioners in a manner more or less analogous to the functions favoured by the Incorporated Law Society, is a point of desirable reform that will secure the cordial approval of the majority of practitioners. But, after all said and done, the cardinal principle of all future amelioration of the lot of medical men lies in the recognition of the duty of the State to protect the safety of the subject by the prevention of irregular medical practice. One of the steps advocated strenuously by The Medical Press and Circular has been the appointment of a Royal Commission upon quacks and quackery, a proposal that has been most ably advocated by Mr. H. Sewill. There could hardly be a more potent instrument for the education of the public or a more efficient means of securing data for legislative action. Were the medical profession generally to adopt this item as a leading part of their policy, there would be a prospect of the appointment of such a Commission in a not remote future. Meanwhile, it is the duty of those who wish for reform in the present condition of professional life to educate the public on these matters and others of a cognate character.

CURRENT TOPICS.

Visitors in Hospitals—A Fatality.

An unfortunate occurrence last week at the Royal Hospital for Incurables in Dublin—an excellently-managed institution—is a painful example of the evil wrought by ignorant but well-meaning folk. A patient, hopelessly ill of consumption, was found one morning in a comatose condition, having concealed near him an empty chlorodyne bottle and a flask of sulphonal tablets. Being roused with difficulty, he stated that the drugs had been brought to him by a lady visitor whose name he refused to give. In spite of treatment, the patient died some hours later, and there was no doubt his death was due to the drugs. The governors of the hospital have a stringent rule against visitors bringing any presents to patients without these passing through the hands of the lady superintendent, but everyone who knows anything of hospital management knows how difficult it is to see that such a rule is rigorously obeyed, especially in the case of small articles. The incident is an example of the dangers of self-drugging, to which we are well accustomed, though it is not often that the fatality occurs in the case of a patient in a hospital. It is appalling that well-intentioned people, like the lady who is responsible for this poor man's death, will interfere with their ignorant advice even with patients for whose sorry need provision is made.

Falmouth and its Poor.

The extraordinary meanness of some public authorities in dealing with their medical officers is past comprehension. It appears that the Falmouth Board of Guardians pays the medical officer to the workhouse the princely sum of £20 per annum, out of which medicines have to be supplied. After this the parson of the "Deserted Village" would presumably deem himself more than passing rich with £40 and no out-of-pocket expenses. The Local Government Board have very properly interfered, and tried to show this shabby authority how little it appreciates its duties to the poor, whose official guardian it is. One of the inspectors, Mr. Preston Thomas, was told off to make representations to the Board, and he pointed out to it that this salary worked out at 7s. 8d. a week, and if the cost of drugs was deducted, the medical man would only clear 5s. or 6s. a week. "About the amount a boy was paid for scaring crows," said the Inspector, and he added "that it was not reasonable to expect an officer to carry out his many duties for such remuneration." The effect of this admonition was that a motion ws made that on the present officer vacating his position the salary should be raised to £35—perhaps as modest a proposal as was possible. But even this humble suggestion was flouted by the Falmouth Bumbles, and the old heartless sweating is to continue. Falmouth can hardly expect much recommendation as a health resort from medical practitioners when its authorities are so glaringly and fatuously unjust in their public dealings.

Dairyman's Diagnosis.

British law, although in the main of monumental soundness, is nevertheless riddled with much foolishness. Take the matter of milk, which is fenced around by a perfect maze of contradictory and defective legislative compromises. To attempt to review the whole situation would be to write a volume, but a few words may be said on one phase of the question in order to illustrate our original proposition. It is provided that it shall be unlawful for any cowkeeper or dairyman to allow any person suffering from any dangerous infectious disorder to be engaged in the production, storage, or distribution of the milk. Unfortunately, the first diagnosis in this case must be made by the dairyman, before calling in a medical man. A better plan would be for it to be rendered compulsory upon the dairyman to call in a medical attendant to every case of illness of persons in his employ. Should there be the slightest doubt as to the exact nature of the malady, the medical officer of health should be at once called in, with full powers to apply any necessary or desirable tests, bacteriological or otherwise, that may be indicated by advanced medical science. Were the whole of the Milk Acts to be drawn up on modern lines of public health administration there is little doubt that a vast amount of good would be conferred upon the community by the lessening of milk-borne maladies.

Ambulance Alarms.

The proper organisation of first aid is clearly a matter of importance to the modern citizen. Needless to say, the rapid and safe transport of injured persons is, in many instances, no less essential to successful treatment than the existence of a well-equipped hospital at the end of the journey. Ambulance stations are now available in London and some other large cities, while various hospital, municipal, and police services are also available for the same purpose. Recently it has been proposed to construct motor ambulances, each carrying a skilled attendant who would be able to apply first aid on the road to hospital. The ambulance centre, to be of any general service, must obviously be kept in touch with various parts of the district in which it lies by telephonic communication. So far as railway stations and large centres of industry are concerned, a good suggestion has been made by Dr. J. S. Rodgers, of Dundee, namely, that an ambulance alarm should be installed after the manner of a fire alarm. The call being made, the trained ambulance men would fall in at a given spot, just as those trained in fire-drill would rendezvous at the fire signal. The suggestion seems practical, and should be brought to the notice of the Ambulance Associations of the United Kingdom.

The Preventive Extermination of Rodents.

Science having demonstrated the part played by rats in the spread of plague, it is meet that science should point out the remedy for the evil. For various reasons the extermination of rats is a matter of great difficulty, although a host of contrivances have been called into requisition from time immemorial. The clumsy method of the time-honoured rat-catcher, and the wiles of the gin, however, will in future be discarded whenever extermination is attempted on any large scale. The old-fashioned phosphorus paste and other vermin poisons killed off a small number of rats in detail, but were dangerous to other animals, and rats soon learnt to avoid them. An ideal destructive agency would be some form of poison which would be greedily devoured by the rats themselves, which would spread infection through other exposed rodents, and would be harmless to other forms of lower animal life. Such an agent is thought to have been supplied by Dr. Danysz, of the Pasteur Institute, in the form of a virus, which is a bacteriological preparation conveying a fatal disease to which only rats and mice are susceptible. The culture is obtained from a variety of Loeffler's *bacillus typhimurium,* which affects house and field mice, but not rats. This virus has been laid down successfully in some of the London underground tube railways, where the rats had been in the habit of short-circuting electric currents by gnawing away the insulating sheaths, but in Australia experience has not been so favourable to its claims.

Sleeping Engine Drivers.

THE special report of the recent railway accident at Shrewsbury, whereby the lives of eighteen persons were lost, not to mention a large number of injuries in addition, points to a serious menace to the public safety. The only theory that can be formed, after a careful investigation of the facts of the case, is that the engine driver—and perhaps the fireman, also—was asleep at the time of the accident. There was no evidence whatever either of drunkenness or of incompetence, but there is a damning record of long hours of night work during the preceding week. Colonel Yorke, the Government official who held the inquiry, apparently entertained no doubt whatever upon this point. The matter, clearly, cannot be permitted to rest there. In the interests of the travelling public it will be necessary to institute some kind of control over the hours of railwaymen, not only of those engaged upon the engines, but also at the signals and along the lines and at the stations generally. The principle of fixed hours of labour has been repeatedly laid before Parliament in the case of the miners. How much more important is such a curtailment within what may be termed physiological limits required for the men to whose hands the safety of millions of our fellow-countrymen—not to mention ourselves—is entrusted every year. Were the hours of railway servants compulsorily reduced to a reasonable limit, and were a periodical medical examination instituted at the same time, there is every likelihood that the number of mysterious railway collisions would thenceforth be greatly reduced. It is to be hoped that Parliament will lose no time in enforcing the moral of the Shrewsbury disaster.

The English College of Surgeons Referendum

THE somewhat novel experiment of the Royal College of Surgeons of England, in referring the question of the admission of women to their diploma appears to be raising a good deal of interest amongst members. It will be remembered that the two questions referred ran as follows:

1. In your opinion, is it desirable that women should be admitted by examination as members of the College?
2. In your opinion, is it desirable that women, after admission to the membership, should be admitted by examination as Fellows of the College,

To these questions the members were asked to answer "Yes" or "No." It has been stated in certain quarters, however, that many members are prepared to answer only on conditions. It is further rumoured that an appeal is to be sent round to members by those who hold that view asking them to disregard the official request, and to send in their answers in their own form. In some sort of remote way this attitude, assuming that it really exists as reported, would appear to reflect the desire on the part of a majority of members to be allowed to share with the Fellows in the government of their own corporation. Be that as it may, it is somewhat curious that a situation of the kind should be rendered possible by the progressive action of the Council in adopting the Referendum, and in actually endeavouring to ascertain the wishes of members in a proposed step of vital importance to the future of the College. The incident suggests that there is, after all, no insuperable obstacle to the ultimate broadening of the basis of control of this ancient and illustrious corporation.

Domestic Preventive Medicine.

A PRACTICAL step has been taken by the Women's National Health Association of Ireland in an attempt to mitigate the sordid curse of tuberculosis amongst the poor. Lady Aberdeen has written from the Viceregal Lodge announcing that the visit of a nurse can be secured to the house of any patient suffering from the malady in question. In this way patients can be taught how to treat themselves, and how to prevent the infection being spread to other persons. A Samaritan Committee of the Dublin Branch of the Women's Association will follow up, so far as possible, with food, blankets, and other absolute necessaries of treatment. This scheme seems to be more rational and worthy of support than the founding of costly sanatoria, destined for the most part for the use of paying patients. The only effectual way of dealing with human tuberculosis is to deal with it in the home. It is abundantly clear that every case allowed to remain untended in a poor environment becomes a standing source of infection for all persons in his vicinity. Every such patient whose danger zone is curtailed or abolished by the Women's Association of Ireland is therefore a distinct gain to the community. Lady Aberdeen is to be congratulated upon the directness, the simplicity, and the practical and humane efficiency of her scheme.

"Style and Appearance" in Poor-law.

THE qualities that lead to sucessful practice are numerous, as the newly-qualified man is apt to discover to his cost when he plunges into the sea of professional life. Amongst other things, there can be little doubt that what is known as the "bedside manner" is not a little valuable to its fortunate possessor. There is no need here to attempt to analyse the qualities that contribute to that particular method, or to show that its underlying basis is one of politeness and good breeding, apart from professional virtues. But it certainly is a little startling to find a Board of Guardians insisting upon the necessity of "style and appearance" in selecting an assistant medical officer. The course hitherto adopted, we understand, has been to leave the selection of the candidate to the medical officer. Under the present arrangement, three candidates are to be interviewed by the Board. It is to be presumed that body, which clearly has the courage of its own opinions, will be guided in its choice not so much by the medical qualifications and experience of the candidates, as by their "style and experience." Under these circumstances it is conceivable that a short series of lessons in deportment might be of advantage to young medical men in search of appointments. Possibly a similar spirit may influence many other Boards of Guardians, inasmuch as their decisions are often of a most unexpected and puzzling nature.

Hospital Anæsthetists.

The question of the administration of anæsthetics in hospitals is likely to attract a considerable amount of attention in the near future. Owing to the absolute lack of trustworthy data it is impossible either to accept or to reject the views of certain leading anæsthetists who assert that fatalities are in the main due to the capabilities and experience of the individual administrator. In any case, it is the duty of hospital authorities to place patients on the safest possible footing. If it be necessary, for instance, that a general anæsthetic should be administered by a senior student or one of the medical staff, then it should be made an obligatory condition that (*a*) he should show that he has received a special technical training in anæsthetics, and (*b*) that he be always under skilled supervision. We note that at Guy's Hospital two new anæsthetists have been appointed. The good anæsthetist must be born as well as made. There are in this way many general practitioners who are excellent anæsthetists. The difficulty is how to find them, but they would certainly be admirably fitted as recruits for the large staff of anæsthetists required for all large hospitals. A small honorarium would have to be granted in return for their exacting work, and the question of pluck for the position might possibly be met by making the tenure of the post subject to a preliminary six months' trial.

Cerebro-Spinal Meningitis.

The recrudescence of "spotted fever" in some parts of Ireland warns us of the curiously stubborn nature of this disease. When once it has obtained a footing in a locality it is apt to recur again and again, long after it has apparently taken a final departure. Its passage from port to port, and from town to town can further be traced, as a rule, with unerring accuracy. The invasion of cerebro-spinal meningitis is usually heralded by one or two stray cases, and it may be some time before the inevitable epidemic follows. In our present state of knowledge it is impossible to take special preventive steps with any certainty that the disease is being directly attacked. On these grounds London, which has had a fair number of "herald" cases, must be held to be yet within the danger zone so far as epidemic cerebro-spinal meningitis is concerned. All medical men connected with hospitals will do well to bear that fact in mind. Out in the Hague, by the way, it is reported that the malady, which has hitherto appeared only in isolated cases, has broken out in epidemic form in a village near Utrecht, where several deaths have already occurred.

PERSONAL.

Sir R. Douglas Powell has been re-elected President of the Royal College of Physicians of London by a large majority.

Sir Frederick Treves has gone into his quarters at Thatched House, the royal residence at Richmond which was recently placed at his disposal.

Dr. T. C. Shaw, Lecturer on Psychological Medicine at St. Bartholomew's Hospital, has been elected President of the Society for the Study of Inebriety.

Dr. Waller and **Dr. Mears** have been respectively reappointed Director and Treasurer of the Physiological Laboratory of the University of London.

The Lord Chancellor has placed Dr. R. G. Nesbitt, Dr. H. Davis, sen., and Dr. J. C. Mackay on the Commission of the Peace for the County of Cornwall.

Dr. Wm. E. Fothergill, Lecturer on Midwifery, Victoria University, has been elected Honorary Assistant Gynæcological Surgeon to the Royal Infirmary, Manchester.

Dr. St. Clair Thomson has been appointed representative of the University of London at the International Laryngo-Rhinological Congress, to be held at Vienna.

Professor von Jacksch, of Vienna, is said to have discovered a method of preventing the burning of the skin which so often results from the operation of X-rays.

Dr. Dawson and **Dr. J. R. Connell, LL.D.**, have been appointed Treasurers, and Dr. Donelan and Dr. Fleury Secretaries of the Executive Committee formed to promote a memorial to the late Dr. Connolly Norman.

Mr. Christopher Martin, Surgeon to the Birmingham and Midland Hospital for Women, will give the Ingleby Lectures of the University of Birmingham on May 7th and 14th. His subject is "Myoma of the Uterus."

Dr. James Porter, who has been appointed Director-General of the Medical Department of the Royal Navy, saw much service in the Boer war, especially at Stormberg, Magersfontein and Belfast. He has recently been in command at Haslar Hospital.

The Council of the Incorporated Institute of Hygiene have decided to promote a special exhibition, illustrating the requirements of infant life and the care and health of children, which will be opened, under distinguished auspices, on June 15th, 1908.

Army Medical Service.

An examination of candidates for thirty commissions in the Royal Army Medical Corps will be held on July 29th and following days. Applications to compete should be made to the Secretary, War Office, London, not later than July 20th, on which date the list will be closed. Candidates who are over the regulated limit of age at the date of the examination will be permitted to deduct from their actual age any period of service in the field after October 1st, 1899, that they could reckon towards retired pay and gratuity, if such deduction will bring them within the age limit. The presence of candidates will be required in London from July 27th.

A Clinical Lecture

ON

INTERNAL SQUINT.

By PATRICK MAXWELL, M.D.Ed., F.R.C.S.I.,

Ophthalmic Surgeon to Jervis Street Hospital; Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin.

Gentlemen,—There are three kinds of internal squint—mechanical, paralytic, concomitant.

1.—An internal squint may be caused by orbital tumour, inflammatory exhudation, or other mechanical condition. The diagnosis is not very difficult. If there is anything in the orbit sufficiently large to rotate the eye to one side, it will also push it forwards. The projection of the eye causes the lids to open widely, giving a characteristic staring appearance. The power of turning the eye outwards is usually completely lost, and movement in other directions is also much restricted.

2.—Internal squint due to paralysis or paresis of the external rectus muscle.—In this case the power of turning the eye outwards is lost or restricted, but movement in other directions is normal.

Let us suppose that the right external rectus is paralysed. Make the patient turn his face straight towards you, and tell him to look at the bridge of your nose. You will observe that the right eye squints inwards. In the position you have placed him he is, strictly speaking, not using any of his orbital muscles. What, then, rotates his eye in? We must remember that all healthy muscles are always in a state of slight contraction or tonicity. The orbital muscles are in pairs, and, under ordinary circumstances, balance one another. When the external rectus is paralysed, it has lost its tone, and is overcome by the internal. Now ask the patient, without moving his head, to follow your finger with his eyes. When he looks to the right the squint increases; when he looks to the left it decreases or vanishes altogether. This is because, in looking to the right, the external rectus of the right eye and internal rectus of the left are employed. The left eye moves normally, but the right cannot pass the middle line. On the other hand, when the patient looks to the left, the external rectus of the left eye, and internal rectus of the right, are employed. Both muscles are healthy, and the movement is properly performed.

Now ask the patient to look at some point a little below your chin. Hold your hand before his left eye (the sound one) in such a way that it cannot see the object, but you can look at both his eyes. Observe what happens. The right eye ceases to squint, and the left turns in. This is called the secondary squint. Often on removing your hand the eyes remain in this position for a time. On covering the left eye, the primary squint is at once restored. Make the squint alternate a few times from one eye to the other, and you will readily perceive that the amount of deviation in the left eye is the greater of the two. At first sight this seems contrary to expectation, but the explanation is simple enough. When he uses the left eye the squint in the right is caused only by the unbalanced tone of its internal rectus. But when he tries to use the right eye he finds that he must strongly exert the external rectus to get it to the middle line; that is, he must perform the movement of looking to the right. Now, in looking to the right, an equal impulse is given to the right external rectus and left internal rectus. Neither of them can be used alone. The right external rectus in this man responds feebly, or not at all, to the impulse, and therefore turns very little, the left internal rectus responds normally, and turns a great deal.

In the figure, A and A^1 represent the directions of the visual axes in a normal case. In paralysis of the right external rectus, the primary squint is represented by the angle A R B. If covering the left eye had made it revolve only through the angle A^1 L B^1, the primary and secondary squints would have been equal. But the left eye rotates through the angle A^1 L C, while the right rotates through B R A. Therefore the secondary squint equals the primary *plus* the difference in the mobility of the two eyes.

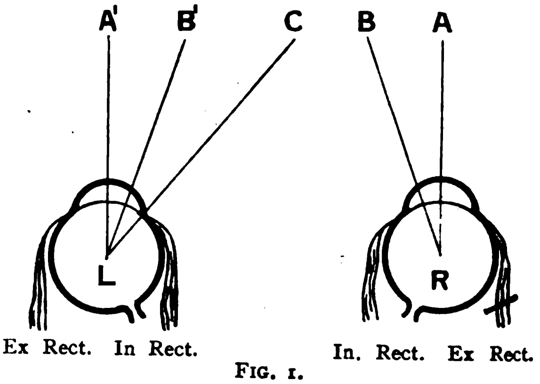

Fig. 1.

Sometimes the patient prefers to use the paralysed eye because its vision is better, or simply because it is the "master eye." He then produces a secondary squint in the sound one In such a case the patient and his friends think that the lesion is in the sound eye, and the medical adviser may make the same mistake unless he makes the squint alternate. The eye that squints *least* has the paralysis.

The patient complains of diplopia, or double vision. To reduce this as far as possible, he often carries his head turned to the paralysed side, which necessitates his turning the eyes the opposite way, reducing the squint thereby to a minimum.

Paralytic squint may come on at any age. There is often a history of syphilis, rheumatism, or tubercle.

3.—Concomitant convergent strabismus.—This is by far the commonest kind of squint. It is called concomitant because it does not increase or disappear when looking to one or other side, but *accompanies* the eye in a fixed degree in all its movements.

The vision of the squinting eye may be as good as that of the sound one, but is usually much worse. This may not be known by the patient or friends. It is well to point this out before performing an operation, otherwise it may be very naturally supposed that you have damaged the eye. Nothing can be seen by external or ophthalmoscopic examinations to account for the defect of vision. The primary and secondary squints are equal. In the vast majority of cases there is no diplopia, even where the vision of each eye taken separately is normal. In those rare cases where diplopia exists it does not trouble the patient, because it is only by a conscious effort that it can be perceived. This form of squint comes on in childhood, usually between the ages of 2 and 5 years. It is not associated with any constitutional disease. It is sometimes periodic—*i.e.*, it is only occasionally present, and comes on when the patient is trying to see anything accurately; or it may be alternating—*i.e.*, though always present, it is sometimes in one eye, sometimes in the other.

Donders made rational treatment possible by the discovery that internal squint is associated with hypermetropia. Fig. 2, though somewhat fanciful, will help you to follow the explanation. A pair of normal eyes, when looking at an object at six or more metres distance, will have their visual axes practically parallel, and will look along the lines D and D^1, but if the object is one metre distant, the visual axes will converge one metre angle. If the object is at half a metre, the eyes converge twice as much—*i.e.*, two metre angles, at one-third metre, three metre angle, and so on. Again, the normal or emmetropic eye is naturally focussed for distance, and requires to make no effort to see clearly. But, as the object approaches the eye, the latter must accommodate one diopter at one metre, two diopters at half-a-metre, and so on. It is therefore evident that to see an object clearly at any given distance the eyes must accommodate a certain number of diopters, and must at the same time converge the same number of metre angles Now movements that invariably occur together are governed by a common co-ordinating centre.

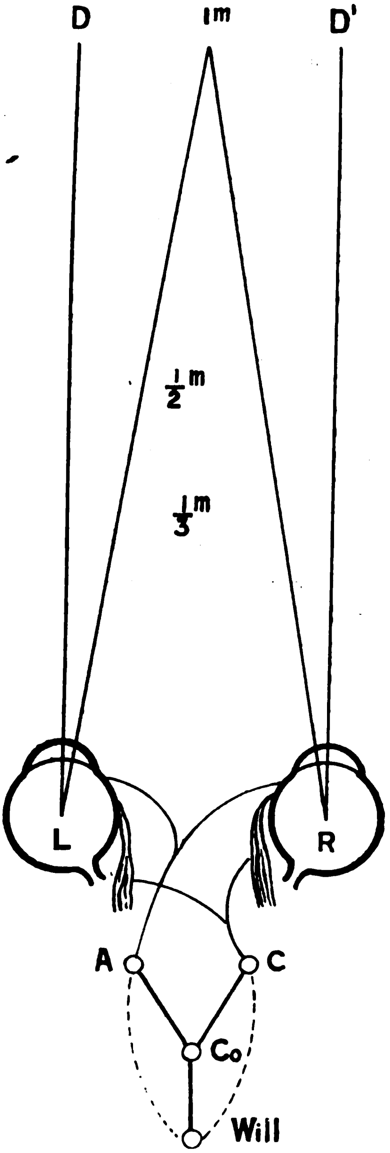

Fig. 2.

Now, if you "will" to look at a near object, an impulse passes from the cortex to the co-ordinating centre for near vision Co. It is here broken up into two impulses, which pass (1) to the centre for accommodation, A, and thence to the ciliary muscle, (2) to the centre of convergence, C, and thence to the internal recti of each eye.

Let us suppose that we are dealing with a case of hypermetropia, say, of three diopters. When looking at a distant object, it is necessary, if both eyes are to be employed simultaneously, that the visual axes must remain parallel. The converging centre must therefore remain passive. But as the accommodating centre is associated with it, it must also remain passive. The vision is consequently blurred because the image tends to fall behind the retina. Acute vision can only be obtained by focussing three diopters. But this necessitates a convergence of three metre angles—that is to say, the visual axes meet at one-third of a metre in front of the patient's face, and from thence diverge to either side of the object. The patient, while maintaining this convergence, can look to the right until the visual axis of the right eye cuts the object. The left eye now appears to be turned very much in, or he may look to the other side till the left eye looks at the object and the right appears turned in. If the vision of the two eyes is much the same, it is a matter of indifference which he uses, and the squint alternates. But if there is a difference, he selects the better eye to look with, and the squint becomes fixed in the other.

The patient is in this dilemma. If he is to retain the advantage of binocular vision he has to put up with blurred vision from insufficient focussing. But if he must see clearly he can only use one eye. For the first two or three years of life he adopts the former, but when he begins, as his mother says, to "notice" things, he prefers the latter. At first the squint is periodic. It then becomes more and more frequent till it is permanent. At the beginning it is entirely spasmodic, but ultimately, from the habitual faulty position, it becomes organic.

Donder's theory is proved by the effect of suitable convex glasses. These remove the necessity for excessive accommodation. Excessive convergence therefore ceases at the same time. In an early case a marked diminution of the squint is instantly produced by the proper spectacles, and it may completely disappear after wearing them continuously for a month or two. Cases of old standing, in which the squint has become organic, cannot be cured by glasses, but it is always diminished by their use. This is quite evident by measuring the angle before and after with the perimeter.

The interesting question now arises: Why do the great majority of hypermetropes not squint? There are several reasons:—

(1) The two dotted lines in Fig. 2 are meant to indicate that the will can reach either the centre for accommodation or for convergence, without going through the co-ordinating centre. Place two prisms of 12° in a trial frame, base inwards, and read through them at quarter-metre distance. You have to focus four diopters, but the direction of the light is so altered that your visual axes remain parallel. You are using the centre for accommodation alone. Your eyes after a time feel tired. The fatigue is due to the resistance which is offered by this unusual path in the brain. Conversely, if you put on a pair of strong convex glasses, which do away with the necessity of accommodation, you have to employ the centre for convergence alone. In this case also your eyes get tired. The amount of convergence or of accommodation that can be exerted independently of the other varies in different individuals. If a hypermetrope is able to exert the excess of accommodation required, and has the instinct for binocular vision, he is impelled to make the effort. An impulse by an unusual route at first passes with difficulty, but by constant repetition passes with increasing ease. The great majority of hypermetropes are able to make the effort, and thus avoid squinting, but many are never able to do so with perfect ease. They suffer from asthenopia, and require to use convex glasses.

(2) In the lower vertebrates, such as the fish, the visual axes diverge about 180°, so that each looks directly outwards. In the process of evolution they come to look more forwards, till in the higher mammals they are parallel when at rest, and can be made to converge for near objects. The orbits, however, in all, including man, remain somewhat divergent. Hansen Grut made a large number of observations in the dead subject, and found divergent strabismus very frequently in persons who had no squint during life.

The same has been observed in persons under deep narcosis. This condition of latent divergence is very common in hypermetropes. If a person has, let us say, three metre angles of divergence and three diopters of hypermetropia, he must employ three metre angles of convergence and three diopters of accommodation to obtain parallelism of axes and perfect retinal images. He can then proceed further with a proportional increase of each, to see near objects. But all this is easily done, because it is carried out by the normal mechanism of the co-ordinating centre. Both latent hypermetropia and latent divergence are, as a rule, masked by continuous muscular action. As it requires atropine to reveal the first, so chloroform will unmask the other.

(3) The binocular instinct: When one looks directly, with parallel axes, at a distant object, an image of it is produced on each macula, yet the mind perceives only one object. We say that the two images are mentally fused into one. If the object is now moved nearer along the axis of one eye, its image will still be formed on that macula, but the image in the other eye will be to the outer side of the macula. These two images cannot be fused, and diplopia is produced. In normal cases the dislike for diplopia, or the desire for fusion, is so imperative that before the individual is consciously aware of diplopia he has converged enough to bring both axes to bear on the object. However rapidly an object is moved, vertically, horizontally, or to and fro, if it is followed by *one* eye, it is followed by *both.* This instinct has been shown by Worth to have begun between the sixth and twelfth months, and it will overcome any tendency to squint from hypermetropia or any cause other than actual paralysis. Its development, however, is sometimes delayed. If a squint should come on at this stage, the patient never gets a chance of producing fusion, and the instinct is never acquired. If the squint is removed, the binocular instinct can be restored up to the sixth year.

(4) An incomplete power of suppression. All sensory impressions can be more or less suppressed, *e.g.*, in a Babel of conversation in a crowded room, one can converse with his neighbour, and, if sufficiently interested, will hear no one else. A patient with diplopia must give his *attention* to one image at a time. But the other image forces itself upon his notice, causing great confusion and distress. If an adult acquires diplopia, he can never completely suppress the false image as long as he lives. But children up to six years can very quickly learn to suppress. Though they may have fairly good vision in each eye separately (the other being covered), yet, when both are open, the squinting one is to all intents and purposes blind. After a time the act of suppression becomes so habitual that the patient is unable to avoid exercising it, even when the other eye is covered. Even in comparatively young children the vision of the squinting eye is often reduced to the counting of fingers at a metre or two. On the other hand, you may find cases much older in which the vision is very much better. The presence or absence in a greater or less degree of the power of suppression is therefore an important factor in determining whether a squint shall occur or not. If the squint is to remain untreated, this faculty is an advantage to the patient. But it is a most fatal gift to those whose eyes have been made practically straight, but in whom suppression has become a permanent habit. It, of course, renders binocular vision impossible.

Let us now pass briefly to treatment.

(1) In mechanical squints remove, if possible, the cause.

(2) A paralytic squint may resolve with or without the help of constitutional remedies even after six months. It is therefore safer to defer an operation till a year after the onset. The paralysed external rectus can then be advanced. This will help the patient to see single without having to turn his head so much to one side. But he will still have diplopia when looking to the paralysed side.

(3) In concomitant squint don't think of a tenotomy the moment you see the case. On the other hand, never send a child away "till it is old enough." The younger the child is, the more you can do for it.

Choose spectacles by retinoscopy under atropine, deducting half a diopter. Glasses should be worn constantly except in bed till the case is finished.

Prevent deterioration of sight in the squinting eye. Where the sight is already very bad, it may be wonderfully improved by bandaging the good eye for even a few days. It is usually sufficient to keep the good eye under atropine. The child is thus encouraged to use the bad eye. Its vision improves, and may even become the better of the two In this case the squint goes to the other eye. The atropine should then be stopped, to be resumed again in either eye as required.

The angle of the squint should be measured at the first visit and at intervals of a month or so afterwards. As long as it keeps decreasing, trust to the spectacles, and prevent loss of sight in the bad eye.

When no further improvement seems likely, an operation should be performed.

The space at my disposal is now exhausted, but I would advise all who would undertake the cure of squint to consult some special work on the subject. I know of no better guide than "Worth on Squint." His method of fusion training should be specially studied.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Albert Robin, M.D., of the Paris Academy of Medicine. Subject: "The Medical Treatment of Phlebitis."*

ORIGINAL PAPERS.

ON ARREST OF
POST-PARTUM HÆMORRHAGE.

By Dr. G. de G. GRIFFITH,

Senior Physician, Hospital for Women and Children; Lecturer on Obstetrics and in charge of Midwifery Department.

I wish to bring under prominent notice a method of treatment recently begun to be referred to, which I have practised since the sixties, without once having had to abandon it for any other. Before I commenced, I remember we used to follow the then plans resorted to, some of which were subsequently changed for others, as one or more failed to check the hæmorrhage. I need not here recount the many methods, but will immediately state the treatment to which I would call attention.

It is the *compression of the abdominal aorta above its bifurcation.* The compression may be made in two ways: one by laying the fingers of the left hand on the thumping aorta, and compressing it against the spine, the fingers being laid over one side of the aorta, and the thumb over the other, the right hand grasping the uterus and making it contract as much as possible. Sometimes it may be necessary to use the fingers of both hands with the thumbs on the opposite side, and thus compress the aorta against the spine, while also narrowing its calibre by pinching the vessel, the uterus not being held or compressed at all. In some instances I have let the person who was "controlling" the uterus in the ineffectual effort to stop the hæmorrhage before I arrived continue to grasp the organ till I had completely arrested the flow by the aortic compression.

In some cases the left hand, grasping in its hollow the uterus, the edge of the palm of the hand can compress the aorta against the spine, at the same time keeping the uterus contracted in the hollow of the hand, the blood supply to the bleeding part being thus shut off entirely, for all purposes of staunching the hæmorrhage. In many cases I have found catching the aorta between the fingers and thumb just above its bifurcation sufficient to arrest hæmorrhage.

For years I found the foregoing methods sufficient, but in one case to which I was called the hæmorrhage was very severe—had been, before I reached the patient—and as I did not succeed in stopping it at once, it was proposed to use Dr. Atthill's 120° hot water douching. While waiting for the hot water, it occurred to me that the cause of my failure was that the branches given off above the point where I was compressing were large enough to supply the uterus. I therefore shifted the fingers higher, with the happy result of arresting any further loss, except that which was in the uterine cavity and in the uterine sinuses. By thus cutting off the blood supply, there is no need of any other method being adopted to keep the blood to the brain and other vital organs in the upper part of the body except the lowering of the head. Indeed, in cases of almost fatal collapse from forms of hæmorrhage other than post-partum, I have compressed the aorta so that the passing of blood to the lower half of the body could not be felt by the fingers, and thus, as well as by rolling the aorta, when pinched between finger and thumb—and so giving pain—revive the patient, when the pulse could not be felt at wrist, or temple, and but very feeble at carotids.

The question has been asked me: Will you use this plan in all forms of post-partum hæmorrhage? My reply is: Yes, in all forms, be it from uterine inertia, or from tears in the uterus, or any part of the genital tract. For years I have never given a dose of ergot, or any such drug, nor brought with me any means whatever of arresting hæmorrhage, knowing that all I needed were my hands, and not once has there been a failure—much more, a death—though I have been summoned when collapse was severe.

Some years ago, before his death, the late Mr. Cooke, of Westminster Hospital, whose anatomy school our lady students used to attend, on being told by them that I arrested hæmorrhage by compressing the aorta, said: "Oh, but if he arrests arterial, he will cause venous hæmorrhage, because he would be compressing this large vein"—showing them the vena cava. My reply was, and is, theoretically this may be so, clinically and practically it is not.

I have been asked, "Do you stop it at once?" "Yes, within half-an-hour or twenty minutes." When the compression is first applied, there will be some bleeding until you fix the aorta, and close it completely, and then the very irritation set up by compression or by pinching and rolling the aorta about, makes the uterus contract, and squeeze out any blood in its cavity or in its substance. I have always arrested it so quickly that I have never had to get anyone to relieve me because of being tired.

Here I may mention that the pulse at wrist, temples, or anywhere else, is no indication of the aortic pulsation. Sometimes the pulse at other parts can scarcely be felt, while the aorta is thumping violently. This holds good of other hæmorrhage than post-partum. Any severe rectal bleeding may in this way also be controlled, and were the femoral or other arteries of the leg bleeding, this compression would staunch the flow till the bleeding vessels were ligatured.

The compression after the birth of the child is exceedingly easy, the patient being on her back, and, if necessary, the knees well drawn up, the hand or hands are very readily buried in the abdominal cavity, where the aorta is plainly felt, as a rule pulsating vigorously; the intestines offer no obstacle to the compression, as some have said to me they would.

Before removing the fingers or the hands from the aorta, I lift one finger after another slowly—the vulva having been well dried by the nurse, and a clean diaper placed against the parts—and watch to see if the hæmorrhage be quite checked. If so, I cease the compression, but, if not, I renew it, till all loss has ceased.

I may here say that while exercising the compression the violent pulsating of the aorta seems to subside, as the pulses return to the various sites where usually felt.

Another method of arresting post-partum hæmorrhage I found also easy and effective—viz., following down the uterus into the pelvis, and grasping it for a while in this situation, and then, well burying the hand in the pelvic cavity behind the uterus, pushing the uterus as much as possible forward and compressing it against the pubes. In this way also I have arrested post-partum hæmorrhage readily and completely.

For years I have thus taught the ladies studying to be medical missionaries, and shown them that they need not be alarmed at the very worst forms of hæmorrhage if, in their very often isolated situations, they have no other appliances or help than their own hands.

Here I wish to cite a case of hæmorrhage from the carotid occurring after removal, by Dr. Wylie, of the Central London Throat and Ear Hospital, of tuberculous glands from the neck.

The hæmorrhage burst out while the patient was asleep, and evidently she was awoke by the loss. Putting her hand to the dressing, she found it soaked with blood, and woke up the nurse by her. I was sent for, and went at once with Dr. Price. The loss had been so sudden and so great that it seemed as though it would be fatal before the bleeding was staunched. The patient was unconscious, and in what seemed to be a fatal faint from heart-failure.

While Dr. Price undid the dressing and proceeded to stop the hæmorrhage, and while other restoratives were being got ready, I pinched the aorta high up above its bifurcation, and, knowing it gave pain, I rolled it about. The blood supply was shut off from the lower half of the body completely, and kept for heart and brain, and for cardiac and respiratory centres. The patient's pulse at the wrist came back, and she showed signs of feeling the pain I was giving her. She opened her eyes, and, in response to my question, "Do I pain you?" signified that I did.

By slow degrees she came to, and all immediate danger was averted. Had we not been thus enabled to act, the result must have been fatal.

In the most recent book on obstetrics, namely, "Rotunda Practical Midwifery," by Dr. Tweedie, the Master of the Rotunda Hospital, and Dr. Wrench, the Assistant Master, at p. 292, this mode of treatment is very briefly referred to under the head of "Other Methods of Stopping Severe Post-Partum Hæmorrhage:—

"(1) By compression of the aorta: You certainly can stop bleeding by direct pressure on the aorta from the abdomen. We have used this pressure in urgent cases, *when things were not ready*."

At p. 293 occur these few words: "If very urgent, either compress aorta or plunge the hand into uterus."

Dr. Jellett, ex-Assistant Master of the Rotunda Hospital, says in his book, "A Short Practice of Midwifery":—

"Compression of the aorta has also been recommended, and it is undoubtedly of value, if we have an assistant capable of performing it. It is of use while we are adopting local measures for checking the hæmorrhage, as it is at the uterus itself the bleeding must be finally checked."

Mr. Stanmore Bishop also advocates this method, and Dr. Fothergill confirms the value of the treatment in his "Manual of Midwifery," where he says:—

"The merits of this treatment possibly have not been tested by those whose teaching and opinions constitute obstetric 'authority.'"

SEXUAL HYPOCHONDRIASIS

AND AFFECTIONS OF THE MALE GENITAL ORGANS OTHER THAN VENEREAL.

By FREDERICK W. LOWNDES,

Consulting Surgeon, Liverpool Lock Hospital.

Most medical practitioners are consulted from time to time by patients who complain of what they believe to be diseases more or less serious, or at least symptoms of such. These persons are found on careful examination to be in perfectly good health, their ailments being grossly exaggerated, or purely imaginary. They are the most unsatisfactory patients with whom we have to deal. Those practitioners who have for many years seen much of venereal diseases, are by a strange perversity consulted by persons who are firmly convinced that they are the victims of these diseases. Hence the terms "syphiliphobia" and "sexual hypochondriasis." Many years ago a surgeon came from a distance to ask my advice. He believed that he was suffering from syphilis, though he failed to give any history of infection, while there was absolutely no indication whatever of the disease. I failed to convince him of his error, and advised him to consult the late Mr. Berkeley Hill, who also failed to persuade him that he was wrong. He was in practice as a surgeon, and on all other points was perfectly rational. A patient whom I had treated for gleet went to America. He there saw a doctor, who treated him for syphilis, and also told him, after he had paid £20 in fees, that he would require six months more of treatment with additional expense. He decided to return to Liverpool and to see me. On learning his story, which he gave very clearly, I found that there was no proof of any primary infection, and no symptom of syphilis. He assured me that the doctor was a fully qualified one, with American degrees. Though he had perfect confidence in me, he was reluctant to believe that he was really free from the dread disease, so, as he was leaving for London, I advised him to consult Mr. Berkeley Hill. That gentleman afterwards wrote to me that he also had much trouble in reassuring my patient, whom he described as "erratic." He certainly was, in more senses than one. These cases are not numerous, and will probably become comparatively rare.

Sexual hypochondriasis comprises a very large class, both of maladies and patients. I will only notice the more important. Many patients refer their ailments to evil practices committed in boyhood. During the early part of last century it was customary for parents of the upper and middle class to send boys at the age of five to preparatory boarding schools. Among the boys there were some precocious ones, the precocity being unfortunate for him and other boys. The result was well expressed by one who spoke from sad experience. "I learned very little good and much that was very bad." The old Latin saying, *Humanum est errare*, is manifest in some boys yet in infancy. After leaving the preparatory school, these boys went to other boarding schools more distant. Thus parents and sons were separated from childhood to early manhood, with a few weeks' interval at Christmas and Midsummer. A probable reason for what now seems a most reprehensible form of education is, that in those days early marriages and large families were the rule, and not, as now, the exception. These patients are often very difficult to treat. They have read the bills and pamphlets of advertising quacks, whom they have also consulted, paying most exorbitant sums. They then consult a regular medical practitioner, who will, they hope, cure them for a small recompense or none at all. Many of these cases are greatly exaggerated, and a cure may be expected if the patient will follow advice and refrain from brooding over the past. In other cases it is too late; the patient will not settle down to any employment, and is a confirmed hypochondriac, if, indeed, his brain has not become affected. Some years ago an old friend sent me his son for advice. He had acquired evil habits at school; they had become ineradicable; he would not do any work; he spent all his time in consulting quacks, reading their literature, and his state was deplorable. A specialist in mental diseases had pronounced the case hopeless, and I was obliged to confirm this. He was sent to an asylum, where he died soon after. Very recently a man, æt. 35, came to consult me. He gave me a very candid history, but the expression of his face would have sufficed. His father called at my request, and stated that his son's conduct had almost ruined him. Time after time he had obtained employment for him, but it was soon given up, and the unhappy man remained idle at home, a curse to himself and to all around him. It was a sad, hopeless case, the worst features being the entire absence of any sense of shame on the son's part, and the want of all parental control on the part of the father. I have seen and heard of many other cases in adults. It has been suggested, and with much reason, that the evil habit may be regarded as symptomatic of softening or other form of brain disease. It ended so in several cases I saw in addition to the one I have mentioned, and I do not see why this more charitable view may not be the correct one.

More satisfactory patients are those who come to consult us as to the propriety of their becoming married. Some are young men who have hitherto led a continent life, and doubt their capacity to perform their marital duties. In most of the cases their fears are groundless, the genital organs being in a perfectly normal state, while the patient admits having erections and periodical nocturnal emissions. It is remarkable how timid these patients often are, and I cannot help regarding this as a probable explanation of the frequent suicides of bridegrooms-elect shortly before the day of their intended marriage. In other cases the patient has indulged more or less freely in promiscuous sexual intercourse, and feels uncertain whether he ought to marry. In all these cases much may be done by judicious advice and proper treatment. Those men who have led a continent life may be assured that such is the best preparation for marriage. As the late Sir James Paget stated in his lectures to students (a):—"Chastity does no harm to mind or body; its discipline is excellent; marriage can be safely waited for." The late Mr. William Acton, who for many years practised as a specialist in syphilis and venereal diseases, generally enjoined strict continence before marriage. I met him when he visited Liverpool in 1874, and in London in 1875, shortly before his sudden and lamented death. He had just completed and published the sixth and last edition of his work, "The Functions and Disorders of the Reproductive Organs in Childhood, Youth, Adult Age, and Advanced Life." In the preface to this last edition he wrote:—"In conclusion, I would fain indulge the hope that the book may continue to exert, as I trust it has already exerted, some good practical influence upon public health and public morals." That this hope has been realised may be judged from the fact that, though 32 years have passed since the author's death, his book continues to be published and has a steady annual sale. It is still to be obtained from Messrs. J. and A. Churchill, of London, and will well repay perusal by both medical and lay readers. Since it was published I have always kept a copy to show to patients to whom I have recommended its purchase. Many men, young, middle-aged, and elderly, have adopted the suggestion, and have thanked me for it. It is specially useful for those men I have indicated as having led continent lives and who are contemplating marriage. They will find all the information they require, and good advice for their future life.

In the case of men who have not led a continent life, great care must be taken to ascertain whether they have suffered from syphilis, and, if so, whether it has been properly treated with mercury. Great caution must also be taken to ensure that a sufficiently long interval has elapsed since the last appearance of any symptoms of constitutional syphilis, as to make it absolutely impossible to infect the wife or unborn child. However incredible it may appear, I have been consulted by men with primary sores on their genitals who wished to have my sanction to their marriage. This was necessary in order to obtain a situation. It is needless to add that I not only refused my sanction to the marriage, but also to any suggestion made by patients for preventing infection. Proper treatment, perfect cure, and a sufficiently long interval—these, and these only, were the conditions with which I could be satisfied before giving my sanction.

It is pleasant to turn from these cases to those in which our consent may be freely given, and to see them followed by happy marriage.

I pass on to what is the most delicate and difficult point to be considered. In the paper previously referred to, Sir James Paget remarked:—"Many of your patients will ask you about sexual intercourse, and some will expect you to prescribe fornication." He proceeds:—"I would just as soon prescribe theft or lying or anything else that God has forbidden. If men will practise fornication or uncleanness, it must be of their own choice, and on their sole responsibility." These outspoken words of the illustrious surgeon who visited Liverpool at the opening of the Royal Infirmary in 1890, have been endorsed by many leading London and provincial physicians and surgeons. I give them because some clergymen and laymen have told me of some medical practitioners who have been so unwise as to give a contrary opinion. I can only express my conviction that this is very exceptional. It is unhappily too true that many of the men who consult us are not, owing to various causes, open to religious influence, and are unwilling to admit the possibility of living a chaste life. But however forlorn our hope may be we must do our duty. There is an old Lancashire word, "jannock," *i.e.*, downright, straightforward; and, as I have frequently told patients, it would not be "jannock" for me to recommend a course which might expose them to infection. That "continence hath its charms," negative and positive, is a truth known to none more than medical practitioners, who know the large number of men whom lust claims as its victims. There are more continent men than is generally believed, and I can remember even among that much abused class, medical students, many who lived perfectly pure lives.

(a) "Clinical Lectures and Essays, 1875," Sexual Hypochondriasis," p. 986.

The late Charles Kingsley is perhaps better remembered as the novelist than the learned divine, Canon of Westminster Abbey and Rector of Eversley. Yet no man was more bold and outspoken in his denunciation of vice than the author of "Westward Ho!" More than half a century ago he described the position of a young gentleman who had passed his youth at a public school and his manhood at one of the universities. No warning had been given unto him of the temptations to which he would be exposed. In his tale "Yeast," Kingsley observes:—"Love had been to him practically ground tabooed and carnal. What was to be expected? Just what happened—if woman's beauty had nothing holy in it, why should his fondness for it? Just what happens every day—that he had to sow his wild oats for himself and eat the fruit thereof and the dirt thereof also." The author proceeds to condemn strongly fathers of families and his own brother clergy for being to a large extent the cause of this. I need not repeat it, as the times have changed, and it is a far cry from the year 1851 to the present year. I have given priority, as was due, to the leading members of the profession to which I belong; next to the views of a prominent clergyman. I will add the words of the late Thomas Hughes, the learned member of Lincoln's Inn, best and most manly of all writers for boys and men. Following Kingsley ten years later, the author of "Tom Brown at Oxford" wrote: "In all the wide range of accepted British maxims there is none, take it for all in all, more thoroughly abominable than this one as to the sowing of wild oats. Look at it on what side you will and you can make nothing but a devil's maxim of it. What a man—be he young, old, or middle-aged—sows, *that*, and nothing else, shall he reap. The one only thing to do with wild oats is to put them carefully into the hottest part of the fire and get them burnt to dust, every seed of them. If you sow them, no matter in what ground, they will come up with long, tough roots like couch grass, and luxuriant stalks and leaves, as sure as there is a sun in heaven—a crop which it turns one's blood hot and cold to think of. The devil, too, whose special crop they are, will see that they thrive, and you and nobody else will have to reap them; and no common reaping will get them out of the soil, which must be dug down deep, again and again. Well for you if with all your care you can make the ground sweet again by your dying day."

Forty-six years have passed since these plain words of Thomas Hughes were written, and though great changes have taken place in our manners and morals since then, they will apply even to the present day. In bringing this subject before my professional brethren, and with more than forty years' experience as a surgeon, I am most anxious to keep the happy medium between optimism and pessimism. That there have been changes for the better in Liverpool within the last half century is a fact to which I can bear testimony. The "social evil" then existed to an extent, and in so aggressive a form, that it had to be suppressed. The state of morals was then very low among young men of all classes, and prostitution was rampant in the streets. In 1871 the provisions of the Vagrant Act against prostitues, which had fallen into abeyance, was reinforced, and the streets became more orderly. Brothels and houses of accommodation have been dealt with, and almost entirely suppressed. These changes cannot fail to have a good effect. There is also a better moral tone among young men of all classes, vice being no longer regarded as manly, its tendency to degrade men, even more than intemperance, being shown every day. There is also a great reduction in the prevalence, also in the severity of diseases, the result of "illicit" sexual intercourse. Young men in business, who wish to adopt the Latin motto "Excelsior," or the French *noblesse oblige*, can attend evening classes at the university and elsewhere. There are also the gymnasia and the volunteer drill for those who prefer an athletic life.

But while fully recognising all these improvements, for which we ought to be very grateful, I must not omit the other side and see what remains to be done. It is as remarkable as it is to be regretted that fathers do not warn their sons against what may lead to impurity. There is a growing tendency to keep boys at home in their early years, sending them to one of the excellent schools which Liverpool possesses, and of which we may be proud. In all homes where the ordinary decencies and proprieties of life are observed, cleanliness is the rule enforced by parents. The old jug and basin of former times is now replaced by the entire morning bath. Boys ought to be taught to wash their genital organs as much as their face and hands. Those who have a long and narrow prepuce should be circumcised, and I am glad to learn that this operation is more generally adopted. Those boys whose foreskin can be drawn back ought to be taught to do this, and to wash it thoroughly every morning and every night before going to bed. For want of this many boys annoy their parents, teachers, and others in authority by fingering their privates, owing to the irritation caused by the accumulation of the smegma. Some will urge the danger of directing boys' attention to their privates as likely to lead to evil. The danger consists not in cleanliness, but in dirt; not in the knowledge but in the ignorance of sexual subjects. There are among the profession and laity many who know by experience the untold misery and suffering caused by such ignorance. "If I had only known when a boy what I know now, when it is too late," has been said to me by men of all ages.

While I have not ignored the changes for the better in Liverpool, I cannot regard the present state of society without apprehensions for the future. Marriages are on the decline, and, as a necessary corollary, so also are births. To a large proportion of our male population marriage is impossible till middle age, while many can never marry at all. Single life has its honourable side as well as marriage. Many men have deferred or even renounced marriage in order to provide a home for father, mother, brothers, and sisters. All honour to them for it. Other men prefer to remain unmarried for good and sufficient reasons of their own. But the large proportion of unmarried men in this city is an element fraught with danger, and to this must be also added another. The "social evil" is now assuming the insidious and dangerous form of clandestine prostitution, while many girls and young women on the borderland between virtue and vice are to be seen in the streets every night under circumstances and amid surroundings terribly suggestive of a sad future for some, if not all of them. (*a*) I have written nothing to excuse or sanction what is immoral. I have the greatest sympathy for the many men who through no fault of their own but through dire necessity are practically denied the blessings of married life. Even more do I feel for the much larger proportion of women who remain unmarried, knowing as I do the truth of the words of a *confrère*, "The world is a very cold world for single women." It was in Liverpool that Felicia Hemans, the poetess, who gave to the world "The Happy Homes of England," first saw the light. I live in hope that the various causes which have led to the diminution of marriages and births may be removed. The English home with its

> "Life's darling divinities,
> Time-honoured children and wife"

has the merit of being an ancient institution. May we hope that it will be equally enduring?

(*a*) See Report of the Head Constable for 1906, pages 32 to 35.

ON ASCITES RELIEVED OR CURED BY PARACENTESIS. (*a*)

By FRANCIS HAWKINS, M.D., M.R.C.P.Lond.,

Physician to the Royal Berkshire Hospital, Reading.

Mr. President and Gentlemen,—In bringing before you the subject of ascites and its treatment by paracentesis, I cannot introduce to your notice that which is new as regards the method of treatment; indeed, from the very earliest times, paracentesis has been performed in cases of ascites. Erasistratus, of the Alexandrian School of Medicine, did not approve of this method of cure, for he thought the ascites arose from disease of the liver, and that so long as the liver was diseased the waters would accumulate again and again; but Aulus Cornelius Celsus, who flourished in the reigns of the Emperors Augustus and Tiberius, not only recommended that the fluid should be removed by paracentesis, but went a step further when he adds, "This is not a method of cure suitable to every case."

But I will leave a further consideration of these very early writers and come to the time of Sydenham, who, however, does not appear to have valued the operation of paracentesis as a method of cure, for he writes in 1683, "In my opinion—the operation of paracentesis, commonly called tapping, which some practitioners commend, is not less hazardous or more successful than blisters." It is here of interest to note that Sir Theodore Mayerne, a cotemporary of Sydenham, makes no mention in any of his works of paracentesis as a method of cure, or indeed as being performed in cases of ascites. In the days of the celebrated Mead—who, by the way, had his country seat near Windsor, to which he used to be driven in his carriage drawn by six horses—this operation had fallen into great disrepute. Mead states that physicians were often adverse to this operation because the abdomen fills up again, and because, if all the water is drawn off at once, the patient dies; but Mead also points out that such result may be prevented if a binder is placed around the abdomen and kept tight during the process. He records a case of a lady on whom this operation was performed in 1705. After being once tapped, the abdomen was covered with a flannel dipped in spirit of wine, and a bandage tightly applied; there was complete recovery. Mead also states that he knew of many cases whose lives were not only prolonged, but made easy. One of his patients left directions for the following to be placed on her tomb:—

"In LXVII. months she was tapped LXVI. times. Had taken away CCXL. gallons of water without ever repining at her case or ever fearing the operation."

Sharp also wrote in favour of the operation in 1729, and says that, "Though it does not often absolutely cure, yet it sometimes preserves life a great many years." But it is clear that the operation did not continue in favour, for we find Fothergill, in a paper read in 1768, saying that few patients can bear the name of tapping without apprehension or terror, and, further, he writes "That tapping has incurred some part of its disgrace from its being delayed till it could have no other effect than procuring a very short-lived hope to the patient." Fothergill advocated the operation being performed as early as possible, and he quotes cases when recovery had taken place after early paracentesis. Fothergill's paper, however, did not increase the reputation of the operation; but we find Heberden, in 1806, referring to the fact that "it is often necessary to let out the water of the ascites by tapping, but there have been very few instances when the water has not gathered again." Mason Good, in 1825, writes:—"We can often very advantageously draw it" (the ascitic effusion) "off at once by tapping"; and he adds, "various cases have fallen to his lot in which a radical cure has only been completed in this manner." Darwell, writing in 1833, was by no means in favour of the operation of paracentesis. He writes:—"We have frequently had patients tapped. . . . In all these instances, however, the effusion rapidly recurred, and, upon examination of several after death, the bowels were found adhering by old depositions of coagulable lymph." He, however, admits that recovery does take place in rare cases even after repeated tappings. Since this date many cases have been published. Hence Dr. Tanner, in 1854, in the case of a woman in the Hospital for Women in Soho Square, performed paracentesis four times, when there was no recurrence of fluid; the patient died two years later; and in 1859 Dr. Banks recorded a case of ascites where recovery occurred after tapping.

But there was at this time a strong disinclination to perform paracentesis. Flint, of New York, wrote in 1863 a paper entitled "A Clinical Report on Hydroperitoneum," based on an analysis of forty-six cases, proving that dropsical effusion may be removed, and a re-accumulation not occur for a greater or less period. In 1872 two papers appeared in the *Practitioner* on "The Treatment of Hepatic Dropsy," and the different views expressed at that time are of such interest that I venture to quote them. In the paper written by the late Dr. Basham, venesection from the arm, as also drug treatment, was recommended, and then, "when the urine becomes scanty, the breathing oppressed, the lower extremities anasarcous, and the loose tissues of the scrotum and penis infiltrated with fluid, the time has arrived for tapping." The other paper is by one still living, known, respected, and honoured by all—Dr. Frederick Roberts. He writes:—"I now come to the most important part of the paper, which is to advocate the early and, if necessary, repeated performance of paracentesis abdominis in appropriate cases of ascites. There cannot be a doubt that this operation is generally looked upon with much dread, and that it is only performed with the view of giving temporary relief, whereas it may be safely employed as a means of permanent cure so far as the ascites is concerned." Valuable as this paper was, it, I fear, did little more to bring the operation of paracentesis into good report than did the earlier writings of Mead or Fothergill, for though we find isolated cases published, notably by Dr. Lyons, of Dublin, and Dr. McCrea, of Belfast, yet Flint, writing again in 1883, thought it necessary to point out the objections held to early paracentesis, although he himself advocates it, and says that he had, ever since his first paper in 1863, pursued this course of treatment, and he adds the results have appeared to confirm its utility. Some nine years later Bristowe, in a paper read before the Medical Society of London, advocates early tapping in cases of ascites due to liver diseases without waiting for extreme distension, and he records several cases thus cured. Later in the same year Cheadle, in a paper "On the Prognosis and Treatment of Ascites," says that the only effectual plan of removing ascitic fluid in hepatic disease is by paracentesis, and he is convinced that the postponement of the operation until urgent symptoms arise is a grave error.

I will now bring to your notice some cases of ascites that have been under my own care, and when effusion of fluid has subsided after paracentesis. These cases have, with one exception, been under my observation for some years, and the results obtained will confirm the opinion and the teaching of Celsus, Mead, Fothergill, Flint, Frederick Roberts, Bristowe and Cheadle.

Case I.—Paracentesis performed once; patient in good health eleven years after.—F. G., æt. 21, a domestic servant, came under my care in December, 1895. She had always had good health until the previous September, when she had dragging pains between the umbilicus and the symphysis pubis whenever she lifted anything, and about December 3rd she noticed that the abdomen was getting larger. This enlargement gradually increased, and on December 20th she first noticed that her feet and legs were swollen and that she passed less urine. The bowels had always been regular; never any diarrhœa. The periods were also regular, the last having occurred one week before admission. There was an indefinite history of tuberculosis in the family.

She was dark-haired, well developed, and well nourished. The abdomen was greatly distended, more so anteriorly than laterally. The umbilicus was everted, and all the signs of free fluid within the

---

(*a*) **A paper read before the Windsor and District Medical Society.**

abdominal cavity were present. On palpation there was general tenderness all over the abdomen. The heart sounds were normal, the pulse rate 128. The respirations were 28, and there was evidence of some slight œdema at the bases of the lungs. The feet and legs were œdematous. The urine had sp. gr. 1028, acid, with a trace of albumin. The temperature was 101°. Four days later paracentesis was performed, when 12 pints, 5 oz. of clear yellowish-green fluid, of sp. gr. 1025, neutral, with a slight deposit, showing strands of fibrin with a few blood corpuscles, was drawn off, and subsequently a bandage was tightly applied. The day following, on examination, nothing abnormal could be felt within the abdominal cavity. The examination, however, gave considerable pain. I then ordered that mercurial ointment should be rubbed over the abdominal wall, which was to be covered with a thick layer of cotton wool, and then a bandage to be tightly applied, a method of treatment handed down to us from the earliest time, even before the days of Celsus, who states that it originated with Tharrias, whose method was "to apply a discutient malagma and to bind upon it a napkin three times folded with a bandage not too tight." But to return to the case. The fluid did not re-accumulate. There was, however, from time to time severe abdominal pain, which was relieved by the application of an ice-bag. I will now ask you to note that in this case the temperature for four weeks varied from 101° to 102° in the evening, and from 97° to 98° in the morning. The sp. gr. of the urine in this case varied from 1020 to 1030, and on two occasions only—viz., January 21st and 24th, subsequent to the day of admission—was there a trace of albumin. After being under treatment four months, she was discharged. I saw this patient four months later, and could detect no sign of disease. It is now eleven years since paracentesis was performed. This patient is quite well, and has not been ill for a single day since her discharge. She has recently married.

Case II.—Paracentesis performed once; patient in good health fully nine years after.—S. G., a married woman, æt. 46. First came under my observation as an out-patient in May, 1897, complaining of sickness and diarrhœa. There was no evidence of organic disease, and under treatment these symptoms subsided. One month later she noticed that her feet and ankles were swollen, and three weeks later that the abdomen was increasing in size, and on July 27th, 1897, she again came to the hospital and was admitted as an in-patient. With the exception of having scarlet fever as a child she had never been ill. She had four children, the youngest being eleven years old. Her confinements had been normal, and her periods always regular. She had never suffered from epistaxis, hæmatemesis, or melæna. She had been addicted to drink for some time. She was tall, spare, with dark hair, and some slight vesicles over the face. The feet, ankles and legs up to the knees were somewhat œdematous. The abdomen was much distended and very tense, the skin being quite glossy. Palpation gave no pain. There was every evidence of free fluid within the abdominal cavity. The heart and lungs were normal. The urine was scanty, and contained neither blood nor albumin. The temperature was 99.6°. The day after admission she had an attack of vomiting. Twelve days later the œdema of the feet and legs had subsided; the urine was increased in quantity, sp. gr. 1010, with a trace of albumin. On August 20th, thirty-three days after admission, the fluid within the abdominal cavity showing no signs of subsiding, but rather the contrary, paracentesis was performed, and 8 pints, 12 oz., of a turbid, brownish fluid (*a*) was withdrawn. The abdomen was then tightly bandaged. The lower border of the liver was felt about one inch below the costal margin. The fluid did not re-accumulate. The urine increased in quantity, the sp. gr. varying from 1004 to 1010. There was a trace of albumin in most specimens examined, but not in all. The temperature varied from 97° to 99°. After being under treatment one month and eighteen days, she was discharged. In February, 1898, I again saw this patient, and the urine then contained blood and albumin. I have not seen this woman as a patient since, but I made inquiries in 1906, and found that since leaving the hospital she had been daily following her occupation as a charwoman, that she occasionally suffered from pains over the abdomen and slight attacks of epistaxis, and that she had to get up frequently during the night to micturate. She is still living, but has, since the death of her husband, given way to drink. It is now nine years and some months since paracentesis was performed.

Case III.—Paracentesis performed twenty-five times in fifteen months; patient in good health seven years after.—A single man, æt. 43, a gardener by occupation, who stated that he had not known what illness was until August, 1899, when he noticed that his feet were somewhat swollen, that he was losing flesh, his abdomen increasing in size, and that subsequently he had a difficulty in passing urine. On September 6th, 1899, he came under my observation. He had never been a heavy drinker, but had taken a small quantity of whisky every night. He had never suffered from venereal disease, nor vomiting, epistaxis, hæmatemesis, or melæna. He was a thin, spare man, with small dilated venules over the cheeks. His feet and legs were œdematous, there was some slight œdema of the chest wall, and some œdema over the sacrum. The abdomen was greatly distended, and there was every evidence of free fluid within the abdominal cavity. The heart sounds were normal, but there was some œdema of the bases of both lungs. He passed during the first 24 hours 19 oz. of urine, sp. gr. 1016. His temperature was 98°. On September 11th, five days after admission, paracentesis was performed, 23 pints, 16 oz., of clear, amber-coloured fluid being withdrawn. Nothing abnormal could be felt in the abdomen, and the liver dulness was about normal. On September 17th he was again tapped, and 19½ pints were withdrawn. Four days later the urine, which had gradually increased in quantity, was for the first time found to contain blood and albumin; sp. gr. was 1014. On September 30th paracentesis was again performed; 23 pints of fluid were removed; and on October 9th 25½ pints. After this he complained of shooting pains all over the abdomen, and the temperature rose to 99.6°. The œdema of the legs now began to subside; blood and albumin were constant in the urine. The fluid within the abdominal cavity having re-accumulated, paracentesis was again performed on October 25th; 36 pints were withdrawn; and 14 days later 23 pints, 15 oz. He now complained of severe colicky pains, which were relieved by carminatives and warm fomentations. He subsequently became so much better that he was allowed to get up, and go about the ward in a wheel-chair. On November 20th paracentesis was again performed, 29 pints of fluid being withdrawn. The œdema of the legs had now almost entirely disappeared. On December 5th paracentesis was repeated, and 23 pints, 17 oz. of fluid withdrawn. He had now been tapped eight times in four months, and he was so much better in himself that I decided to try the advice of Celsus and let him walk about. He was therefore discharged, being told to return to the hospital in a fortnight. He, however, returned in twelve days. There was now slight swelling of the feet and legs. The urine, sp. gr. 1020, contained a considerable quantity of albumin, but no blood. The fluid had re-accumulated within the abdominal cavity, so, seven days after re-admission, December 26th, 1899, paracentesis was again performed, 26 pints 13 ozs. of fluid being taken away. He expressed himself as feeling greatly relieved. All went on well till January 4th, 1900, when he complained of very severe abdominal pain, and only passed 10 oz. of urine, which contained a considerable quantity of blood. I ordered him to drink freely of distilled water, with the result that on the following day 45 oz. of urine, containing much blood, was passed. Five days after, the fluid having again accumulated, I tapped him once more, withdrawing 27 pints, 15 oz. The following day the urine contained no blood. A few days later he again had severe colicky pains, which were relieved by rhubarb and soda. On January 30th, 19 pints, 15 oz., and on February 20th 35 pints 5 oz. of fluid were removed,

---

(*a*) No note was made of the sp. gr. of this fluid.

and two days later he was again discharged. But I must not take up your time with a detailed account of the subsequent admissions and tappings, as nothing further of any moment occurred; but I will content myself by stating that during a period extending over *one year and three months* in this case paracentesis was performed 25 times, and that he was finally discharged December 21st, 1900. Since then, for now over seven years, he has followed daily his occupation of a gardener, working from six in the morning till five in the evening, and during this time he has not once been ill. I have on a few occasions asked him to come and see me at the hospital, and I saw him only a few days ago, and on these occasions I have found the urine always to contain a trace of albumin, and the sp. gr. has been 1004 to 1010.

Case IV.—Paracentesis performed twice; patient in good health eight months after.—A married man, æt. 50, a foreman on the Great Western Railway, who has never been a drinking man, and had never been ill until five years ago, when he noticed that his feet and legs were slightly swollen. This lasted for three weeks. Since then he had not been ill, or given up work till August (1906), when he had pains in his legs, which subsequently became swollen, the left leg in particular, the right only slightly. Seven days later he had pains in the lower part of the abdomen, which he then noticed was much enlarged. He had vomited several times during the previous fourteen days, and on two occasions brought up blood, about an ounce each time. He was a thin, spare man, with some small venules over his cheeks. Both legs were œdematous, the left much more so than the right. The abdomen was much distended, the surface veins of the abdomen and chest being very distinct. There was free fluid within the abdominal cavity. The heart sounds were normal, but there was some œdema of the bases of both lungs; urine sp. gr. 1020, with a trace of albumin. Seven days after admission paracentesis was performed, and 19 pints of turbid yellow fluid (sp. gr. 1016) withdrawn. A few days later he complained of pains over the lower part of the abdomen. After paracentesis the œdema of the legs subsided. On September 4th paracentesis was again performed, when 12 pints, 18 oz. of fluid were withdrawn. There has been no return of the fluid, no œdema of the legs; on one occasion he vomited. The urine increased in quantity after paracentesis, and was then sp. gr. 1010, and contained a trace of albumin. Although only eight months have passed, I expect he will go on favourably for some time to come. (*a*)

I should just like to ask your attention to the temperature chart. You will note that for 38 days there was an evening rise and a morning fall, varying from 102.4° in the evening to 97.2° in the morning.

(To be concluded in our next.)

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Large Hydatid of the Liver—Operation.—Mr. James Berry operated on a man, æt. 50, who had been transferred from the medical wards on account of a large hydatid cyst of the liver. The patient had had very few symptoms beyond a feeling of discomfort in the epigastrium, and occasional vomiting. Some seven weeks ago diarrhœa became troublesome, and for this he came to the hospital. On admission, he was found to have a large rounded swelling in the region of the liver. The epigastric and the right hypochondriac regions were occupied by a small elastic prominent swelling pushing the lower right ribs forwards and outwards. There was no extension upwards of the liver dulness. There was no jaundice, no ascites, and no evidence of any disease above the diaphragm; there was nothing in the history of the case pointing to abscess of the liver. The man's general condition was good, and there was no elevation of temperature. At the usual weekly consultations it was generally agreed by the physicians and surgeons present that there was little or no doubt as to the diagnosis of a large hydatid of the liver. The operation was very simple, consisting merely, in the first place, of a vertical incision two inches long below the right costal margin and immediately over the most prominent part of the swelling. On cutting through the abdominal wall, a thick, tough layer of fibrous tissue was reached without the intervention of any visible liver tissue between it and the abdominal wall to which it was intimately adherent. On incising this fibrous layer, which was the ectocyst of the hydatid, many hundreds of hydatid cysts varying in size, from a pea to a plum, were turned out. These were all removed by sponging and irrigation. The vast cavity appeared to occupy almost the whole of the normal region of the liver. Under the microscope typical scolices were seen, some of which by their movements showed that they were still living at the time of examination. At the upper part of the cavity the diaphragm could easily be seen pulsating with each movement of the heart. A short glass tube, one inch and a half in diameter, and about the same length, was passed through the abdominal wall, and the whole cavity lightly packed with gauze. Mr. Berry said that a large, round, smooth elastic swelling in the region of the liver could scarcely be anything but a hydatid. He called attention to the fact that the patient had complained of very few symptoms, and was at first inclined to refuse operation. The dangers of leaving a hydatid of such large size, Mr. Berry pointed out, were that it would either burst or leak into the peritoneum, and thus set up peritonitis, or it would suppurate. The elasticity of the swelling in the present case, he said, was so marked that in all probability the hydatid was very near to the surface. The adhesions found between the abdominal wall and the tumour rendered packing of the peritoneal cavity unnecessary in this case. Indeed, the unobliterated peritoneum was not opened at all in the operation. Small hydatids, he remarked, might well be treated by immediate closure of the cavity in which they had been, but for very large hydatids or cysts like the present one, he thought packing and drainage the safer course. The wide, short glass tube, the use of which, he stated, he had learned from Mr. Rutherford Morison, was extremely useful in keeping open the mouth of the cavity, and so facilitating the introduction and the removal of gauze. Mr. Berry pointed out that it was not wise on the part of the surgeon to make any attempt at the operation to remove the ectocyst. The endocyst, on the contrary, usually presented itself in the form of a thick white membrane, easily detachable, and removable without any hæmorrhage, this being by no means the case with the outer fibrous layer constituting the ectocyst. This is always intimately adherent to the surrounding parts, and in the case of the liver, to large hepatic and portal veins; any attempt to remove it is sure to be followed by severe and even dangerous hæmorrhage. Some years ago, at another hospital, he had seen a foolish attempt made to remove the ectocyst, and the patient had died of hæmorrhage within a few hours of the operation. In the case he had just operated upon not a single drop of blood was lost excepting what actually came from the incision in the abdominal wall.

The after-course of the case was uneventful. The glass tube was discontinued eight days after the operation, the cavity having contracted up to a very small dimension. Five weeks after the operation there was still a small cavity remaining requiring daily dressing, but the patient was up and about, and quite well.

(a) I saw this patient quite recently, he was quite well. His liver was enlarged—firm and smooth border-urine, sp, gr, 1014. Trace of albumin.

TRANSACTIONS OF SOCIETIES.

THE ROYAL SOCIETY OF MEDICINE.

Obstetrical and Gynæcological Section.

Meeting held April 9th, 1908.

The President, Dr. **Herbert Spencer**, in the Chair.

Dr. **H. Macnaughton-Jones** read a short communication on the subject of

PRIMARY UNILATERAL TUBERCULOSIS OF THE FALLOPIAN TUBE.

He briefly reviewed the more recent ætiological and histological points bearing on tuberculosis of the female genitalia, dealing with the relative frequency with which the various organs are affected from the vulva to the ovary. The recurrence of primary tuberculosis in any of the genitalia is not common, but a unilateral primary tuberculosis is very rare. His communication dealt with primary unilateral tuberculosis of the Fallopian tube, of which he had met with two instances, and he had one case of primary tuberculosis of both tubes. In all these the rest of the genitalia were healthy. The details of the three were given, and all the removed tubes were shown, together with the microscopical sections. In the case which was the source of this communication, a tubercular pyosalpinx was removed 6½ years ago. She had one twin pregnancy and three other pregnancies since. He had recently to perform on this patient a cœliotomy, 39 days after labour, for an extensive septic perimetritis (the section of the matted adnexa was shown with the epidiascope). There was no evidence of tubercle. She was now perfectly well. All the five children were strong and healthy. Mr. Targett and Dr. Cuthbert Lockyer had made the reports. He had received replies from some 35 leading gynæcologists in the United Kingdom and abroad before bringing the case forward as to the records of such a condition. Only in seven of the home clinics were there records of such a lesion, and in but three of the foreign.

A short communication by Dr. **Kedarnath Das**, of Calcutta, on

THREE CASES OF CÆSAREAN HYSTERECTOMY FOR ATRESIA OF THE VAGINA

was read by the Honorary Secretary. Traumatism during labour in which instruments were used was the cause of the condition in each case. Two of the cases were complicated with vesico-vaginal fistulæ which had resisted attempts to close them, although in one case a recto-vaginal fistula had been closed. In the first case the mother died, probably from the infection of the peritoneum through the vesico-vaginal fistula. In this case the child lived. In the second case the mother lived, but a dead fœtus was removed from the uterus. In the third case both mother and child lived. The author drew attention to the frequency with which vesico-vaginal fistula occurred in India, the distressing nature of the condition, and the relief that can be given in the majority of cases by operation. The occurrence of conception under such peculiar circumstances, and the extra-peritoneal treatment of the stump in the third case, were also worthy of note.

Dr. C. **Nepean Longridge** read a short communication on the

CREATININ EXCRETION OF LYING-IN WOMEN

during the most active period of involution of the uterus. The paper was based on 90 estimations of creatinin, and 180 estimations of the total nitrogen in the urine. The patients were delivered in Queen Charlotte's Lying-in Hospital, and were kept upon a creatinin-free diet during the time they were under observation. The endogenous creatinin alone was estimated. It was found that the creatinin excretion maintained practically a level line, and is probably not increased by the involution of the uterus, a result which is in harmony with the recent work on creatinin excretion. By applying the conception of autolysis to the process of involution of the uterus, it was thought that a clearer idea of that process might be obtained. A very brief *résumé* of the main facts concerning autolysis was given, stress being laid on the fact that it is most rapid in an acid medium and in a bloodless organ. Dr. Longridge had observed that the wall of an autolysing uterus was acid in reaction, and considered that the rapidity of the first stage of involution was due to this fact, and to the fact that the uterus is anæmic during the first four or five days after delivery in a normal case. This anæmia is due to two factors, the retraction of the uterus and the effect of the kinking of the uterine arteries in reducing the blood pressure in them after delivery. Dr. Longridge thought that the conception of autolysis would help to explain many obscure points of uterine pathology, such as super-involution of the uterus, and the changes in fibroid tumours, and would lead to considerable clarification of our ideas in regard to the relation of the liver to the toxæmia of pregnancy.

A paper on a case of

INTRA-UTERINE DEATH OF THE FŒTUS

occurring in six consecutive pregnancies was read by Dr. **Herbert Williamson** and Dr. **Eardley Holland**. The case is recorded of a patient, æt. 24, who had given birth to two still-born children at the 26th and 28th weeks of gestation respectively. Careful examination of the patient and her husband failed to reveal any signs of syphilis, and no history of infection could be obtained. During the course of the next two years she gave birth to two more children, still-born, at the eighth month. In her fifth pregnancy the child was found to be alive in the 30th week, and the induction of premature labour was recommended. Three weeks later she was spontaneously delivered of a still-born child in Queen Charlotte's Hospital. Sections of the fœtal organs stained by Levaditi's method revealed the presence of the spirochæta pallida. She became pregnant again before the menses reappeared, and throughout this pregnancy was treated with small doses of mercury and iodide of potassium. When examined on October 17th the uterus reached to the costal margin, and the fœtal heart could be heard. It was believed that nine lunar months' gestation had been completed, and it was thought advisable to run no further risk, but to induce labour. Labour was induced on November 2nd, and she was delivered of living twins, a boy and a girl. Both children were obviously premature, and the amniotic sac of the female child contained an excess of liquor amnii. The children survived only a few days, and post-mortem neither showed syphilitic lesions nor could spirochætes be discovered in sections of the organs. The authors brought forward the case as a contribution towards the pathology of intra-uterine death, and stated their opinion that Levaditi's method of demonstrating the spirochæta pallida has given a new means of diagnosis and new indications for ante-natal treatment. They discussed briefly—(1) the evidence upon which it is claimed that the spirochæta pallida is the specific organism of syphilis, and (2) the reliability of Levaditi's method for demonstrating the presence of the organism.

Clinical Section.

Meeting held April 10th, 1908.

The President, Sir **Thomas Barlow**, Bart., in the Chair.

Dr. **Leonard Guthrie** and Mr. **Stephen Mayou** showed a boy, æt. 7, with left optic atrophy and right hemiplegia. He had been run over by a cab in July, 1906. He subsequently developed pneumothorax, and three days later became aphasic and hemiplegic on the right side, and blind in the left eye. The aphasia and hemiplegia had improved, but he was still blind in the left eye, and had complete atrophy of the left optic disc. No trace could be discovered of the left common carotid or its terminal branches, which were believed to be blocked, together with branches of the left middle cerebral and left arteria centralis retinæ.

Mr. **Charters Symonds** showed a patient, æt. 52, operated upon in 1904 for malignant disease of the larynx. Complete extirpation was carried out, with removal of the left thyro-hyoid and sterno-hyoid muscles, all surrounding fascia with lymphatics, and the left thyroid lobe. The trachea was attached to the skin above the sternum, and primary union obtained. Professor Gluck's device of inserting a rubber tube into the cannula, and thus carrying a current of air to the lips, enabled the patient to speak so that he could be heard at some distance, and could continue his duties.

Mr. W. S. **Handley** showed two cases of brawny arm of breast cancer which he had treated by the laying of four threads of white silk beneath the skin of the arm from the wrist to the soft tissues on the proximal side of the affected axillary glands and lymphatics. The œdema had disappeared, and the muscular power, previously lost, was gradually returning.

Dr. F. **Hawkins** (Reading) exhibited a man, æt. 43, never a heavy drinker, nor sufferer from venereal disease, who, in August 1899, had œdema of legs, chest wall, and sacral region, with much ascites; heart sounds normal, the urine sometimes containing blood and albumin. The abdomen was tapped 25 times in 15 months, the maximum amount of fluid withdrawn being 36 pints. Since 1900 he had had good health.

Dr. F. **Parkes Weber** showed a single woman, æt. 21, with symmetrical œdema of hands and feet of five or six weeks' standing in the feet, three weeks' duration in the hands; she had also diminished breathing, and voice sounds over the lower part of the left lung, especially in front and below the axilla. X-ray examination showed a shadow over this area; there was no cough or expectoration; slight anæmia, tested by blood count; the temperature was usually about 100° F.; the swelling and cyanosis of the extremities had diminished during rest in bed; the nature of the mediastinal affection was doubtful.

Dr. **Norman Moore** showed a patient, æt. 44, admitted two months ago to St. Bartholomew's Hospital with defective sight and symptoms of myxœdema. After continued administration of thyroid extract, the lethargy, slow speech, and other symptoms of myxœdema had disappeared. He could now walk well, and had no tremor of hands. But the remedy had not made any difference to the optic atrophy. Both discs were atrophied, the left more than the right. The visual field was not markedly contracted, but slightly so on the nasal side. He could perceive light with his left eye, and count objects with his right. Dr. Moore said that he knew of no other case of myxœdema combined with optic atrophy.

Dr. **Graham Forbes** and Dr. F. S. **Langmead** contributed a paper based on 12 cases of

FATAL LYMPHOCYTHÆMIA IN CHILDREN,

the ages ranging from 7 months to 11 years, ten being under 4 years. The disease had an indefinite onset, with increasing pallor and languor, and ranged from two weeks to three or four months, averaging five weeks in duration. Post-mortem examination showed enlarged lymphatic glands, punctate hæmorrhages on pericardium and pleuræ, enlarged spleen, liver and kidneys; no increase in the bone marrow. The disease was probably of microbic origin.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, April 3rd, 1908.

Dr. Finny in the Chair.

DUODENAL ULCER: ITS DIAGNOSIS AND TREATMENT.

Mr. Mitchell (Belfast) read a communication on the above subject.. This was based on a series of nineteen cases which he had operated on during the previous year. Mr. Mitchell first emphasised the unrecognised frequency of the condition, and showed the urgent need for diagnosis, as it was a more serious condition than gastric ulcer, being much more liable to perforate and to lead to fatal hæmorrhage, and also less amenable to cure by medical means. He discussed the ætiology—the greater frequency in men (twenty-three to four of the present series)); hyperacidity as a factor in production; its connection with alcohol, etc. As prominent symptoms Mr. Mitchell placed (1) "hunger-pain"; (2) discomfort after food; (3) local tenderness above and to the right of the umbilicus; (4) hæmatemesis and melæna; (5) early dilatation of the stomach. The position and appearance of such ulcers were then described as they appeared in the living. Mr. Mitchell, in discussing the treatment, thought surgical means (at all events in chronic cases) were the only reliable and efficient method of treatment.

Dr. **Little** said his experience of duodenal ulcer had not been that it was so extensive as Mr. Mitchell indicated. He agreed that it was much more frequent in men than in women, and he had found it much more frequent among private than among hospital patients.

Dr. **Drury** said he had found that his patients who suffered from duodenal ulcer had less of actual pain than of discomfort.

Dr. **Dawson** referred to a case in which pain, occasionally of an acute variety, came on four or five hours after food. It was localised in the spine, and sometimes radiated towards the front on both sides, but there was no pain or tenderness in front of the abdomen. The first symptoms had been dilatation and then the pain; the hæmorrhage which followed was entirely gastric, and for a long time there was no melæna. After it, however, the ulcer was thought to be duodenal. Medical treatment failed, and an operation was successfully performed, when nothing was found in the appearance of the stomach or duodenum to indicate any morbid condition whatever.

Dr. **Moorhead** said they owed a debt of gratitude to Mr. Mitchell for emphasising the seriousness of the condition, and for assuring them that he could recommend operation with a free mind. Hyperchlorhydria had been a typical symptom in the cases of duodenal ulcer which he had seen.

Dr. **Peacocke** asked if the diagnosis of duodenal ulcer had been made by the symptom of "hunger-pain" practically alone, and if it had been confirmed.

Dr. **Bewley** said if the hunger-pain could be considered a proof of duodenal ulcer, the condition would have to be regarded, under the categories of severe and slight, as they found cases which were relieved by food and by medical treatment. Cases in which apparently absolute health preceded a copious hæmorrhage were not so uncommon, and he did not think the diagnosis was so absolutely clear as might be imagined.

Dr. **Cahill** said he had been able to diagnose duodenal ulcer through giving foods of different degrees of digestibility, such as beef and pork, and watching the time relation of the onset of pain.

Mr. **Wheeler** asked if the cases of perforation occurred without symptoms, and whether a diminution in the amount of hydrochloric acid would account for the want of symptoms prior to perforation.

Dr. **O'Carroll** said they might regard gastric cases—other than mere indiscretions—as being either mucogastric and associated with a diminution of acid secretion, or associated with an excess of acid secretion, or a necrotic or ulcerated condition. These three divisions would form a serviceable basis for diagnosis. They might assume that excess of acid was in many cases associated with ulceration in the stomach or duodenum. He hoped that they would in future be able to diagnose the condition at a stage that would prevent cases having to go to operation. Tests for acid were not always absolutely reliable, as in some cases the acidity of the stomach overstayed its emptying, and set up an ache which might be relieved by food. He agreed, of course, that if they could be sure of the diagnosis there should be operation on the spot.

Mr. **Mitchell**, in reply, said he agreed with Dr. O'Carroll's remarks, and had himself declined to operate in certain cases. While it was valuable to have an outstanding symptom that would give a direction to their thought, it would be a mistake to regard a single symptom as infallible. He had not, however, found a case of duodenal ulcer in which there was not "hunger-pain." His experience of the locality of the pain was varied, and he had not found any diminished hydrochloric acid. In reply to Mr. Wheeler he answered, No. The condition of duodenal ulcer might be commoner in the North than in Dublin; since March 5th he had been consulted by ten cases having typical signs, and in four operated on the ulcer was found.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, April 19th, 1908.

At the last meeting of the Medical Section of the Society for Vaterlandische Kultur a number of interesting cases were shown and described.

1. A case of

Epilepsy after Injury.

A young man, æt. 21, was kicked on the head by a horse eight years ago. For 15 months he had suffered from typical bilateral epileptic attacks. The forehead was trephined over the site of a bony depression and a bony process was removed. Along with this was found a lacuna larger in size than a bean, and in it was a cortical cyst the size of a pigeon's egg. Everything went on well after the operation, after which the patient had only two slight attacks.

2. Was a case of traumatic cerebral abscess, in which recovery had taken place.

3. Was a case of recovery after enormous

Prolapse of the Brain

after traumatic cerebral abscess. The patient, æt. 15, was only admitted into hospital a month after receipt of the injury. The opening in the skull was 2 cm. by 4 cm., a piece of brain, very much soiled and the size of the fist, was projecting. There were decubitus, fever, and paralysis of the whole of the right side. After the evacuation and cleansing of a large cerebral abscess, however, complete recovery took place. Even when shown there was spastic paralysis of the whole right half of the body remaining, but the patient could walk in a sort of ataxic fashion, and could make some use of his arms.

4. Was a case of

Meningitis with Formation of Gas.

The patient, a man, æt. 56, had been struck on the head with a stone, and for several days had shown signs of meningitis. The skull was extensively trephined, but this was not successful in saving the patient's life. The injury to the skull was inconsiderable and the dura was intact, but the latter on being incised was found to be covered with a greasy purulent layer with numerous gas bubbles. Although careful search was made the micro-organisms that caused the formation of the gas could not be discovered.

Other cases shown were one of successful extirpation of a cerebral tumour, one of extirpation of a sarcoma from the anterior central convolution. Here the diagnosis was made previous to the operation. The patient was a man, æt. 43, who began three months before with cramps, commencing in the left hand and passing up the arm to the left side of the head. These were followed later by paresis. Death took place 14 days after the operation from meningitis, which was favoured by metastatic cerebral sarcoma. At the operation Prof. Küttner, Breslau, laid great stress on careful arrest of hæmorrhage by stitching round, he removed the bones along with the tumours, drained through two small openings for 24 hours only, and sutured the wound, thus avoiding tamponade, which he rather considered favourable to secondary infection.

Another case was one of laminectomy, and the operation was performed on a patient who the year before had been kicked by a horse on the right side of the face. Some time afterwards distinct symptoms of myelitis appeared, about the region of the upper dorsal vertebræ—or there might be a tumour. The laminectomy was performed over the sixth and seventh cervical and first dorsal vertebræ. The result was negative. Recovery was uninterrupted, however. The speaker expressed the opinion that one could more readily do exploratory operations on the spinal cord than on the brain itself, as the deeper lying cord was less exposed to secondary infection.

Some cases of surgery of the stomach were also shown. There were two in which neither before operation nor at the operation could it be made quite certain whether the disease present was a hard, callous ulcer or was malignant. In such cases of doubt it was better to resect than to do gastrostomy. If the resection were performed with Graser's instrumentarium, with Murphy's button, and after Billroth's second method it was scarcely more dangerous than gastrostomy. If the stomach was so nearly normal as to afford no definite indications, the stools should be examined chemically for blood. In cases of epigastric hernia he always operated, as the stomach troubles associated with it were occasionally due to serious gastric disease.

Two cases of excessive flow of gastric juice were shown. A large quantity of clear, strongly acid fluid was brought up by vomiting, it was generally due to ulcer with or without stenosis of the pylorus. The enormous loss of fluid might lead even to dangerous drying-up of the body tissues. Gastroenterostomy acted favourably, even when there was no stenosis of the pylorus.

AUSTRIA.

Vienna, April 19th, 1908.

Syphilis and Morals.

Prof. Finger opened the inquiry promoted by the profession to combat syphilis at its source. He said this society was first proposed by Wolff, of Strassburg, at an international conference to consider the best way of eradicating leprosy, 1897. Two years later Havenith, of Brussels, after another international conference, succeeded in getting the Belgian Government to adopt certain moral regulations to limit the spread of disease, which have since been adopted in Germany, Austria and France.

Notwithstanding these efforts, the prudery of society still barred the way and prevented progress. To overcome this difficulty, the society adopted the next best method of obtaining expert knowledge from every quarter, and discussing it thoroughly in open conference, and pointing out the gravity of the disease and the daily destruction to life. Prof. Lang next demonstrated its dangerous infection, and how the micro-organisms are transmitted by razors and other utensils. Prompt treatment was a necessity, but good food, proper clothing, and comfortable dwellings were essential. Institutions, therefore, must be established to meet the social demands, for where the moralist fails the physician must commence. Prof. Noorden said that the last ten years had seen an enormous increase of sexual diseases and their consequences. Paralysis was now filling the lunatic asylums, and tabes our hospitals. Diseases of the circulation, heart, respiratory organs, blood and alimentary organs, were no exception to its ravages. One-half of the population in middle life suffered from arterial sclerosis due to syphilis. Every clinician knows the danger of neglecting the primary symptoms, which the patient is unwilling to divulge till the "quarternary" phenomena have set in and probably have undermined the health. Nothing is more tragic than the sight of homes wrecked with this morbid curse, and thence handed down to posterity.

Prof. Escherich followed with a jeremiad for the infant of the infected who innocently enters on a life of misery. He considers there should be a special institution provided for such victims. He divides this class into two divisions—venereal catarrh and genuine syphilis. The first are affected with diseases of the cornea and conjunctiva a few days after birth, which the "Hebammen" of Austria have strict injunctions to obey. The second division is the most serious, and one that is fast decimating the population of France.

From the point of view of psychiatry, Prof. Janregg said progressive paralysis was now recognised as an undeniable result of syphilis occurring within ten or twelve years after the primary effects. In the Austrian lunatic asylums at the present time there were 1,300 of these cases, and a very modest computation assumed an equal number treated at their own homes. This, he thought, comprehended 2 to 3 per cent. of all the syphilitic cases. Tabes spinalis was still more frequent amongst us.

Prof. Ehrmann devoted his attention to the transmission of the disease. The light cases were passed, and great damage done, while the severe cases were concealed till some serious illness arose, when human aid is hopeless. As a representative of the "Krankenkaisen" he considered 0.8 to 3 per cent. far too low for syphilitic diseases among the people, when we know positively that it is over 6 per cent. in the army and 3 per cent. in the militia. Statistics vary, however, as in the south of Hungary it is very prevalent, while the west Alplands have a very small number to record. Again, the calling has some influence on the transmission of the disease, as we find waiters and farm servants the greatest sufferers from the disease. Removal from the home life is a potent factor in the transmission. Our middle classes in this respect were very bad, while the housemaid who has often been blamed stands in a very respectable position, although recent examination of diseases of the nerve and vascular symptoms points to an increase. Isolation of the disease as practised on lepra in the seventeenth century would be the best way to eradicate the disease. Schiff said there was great difference in the frequency of the disease in various trades. He had under notice 300,000 tradesmen who were insured, and found that in the larger industries 16 in a thousand were laid off with diseases attributed to that disease. In some of the branches, however, it was double that number.

Brandweiner reported 7,417 cases, the half of whom were females, which came before him in five years at his clinic. From these he elicited that 67 per cent. were infected before 25 years of age, and 19 between 25 and 30, while the other 14 per cent. were later. Scherber announced that his experience of the disease showed that extra-genital transmission was greater in females than males, as the former was 3 to 4 per cent., while the latter was only 3 per cent. This varied in different localities, as in Russia we find it in many exceeding 70 or 80 per cent.

HUNGARY.

Budapest, April 18th, 1908.

At the recent meeting of the Royal Medical Society, Dr. Bárdos read a paper on

Menstrual Jaundice.

He remarked that he had a few cases of jaundice recurring with every menstruation, and he did not regard this condition as a separate disease, as others do. He had observed and described a case three years ago, and he was able to give the results of the autopsy, as the patient died of an inter-current disease. A calculus was found wedged in the common duct, which seemed to obstruct this passage completely, yet during life probably permitted the escape of sufficient bile to prevent stasis. With the congestion of the abdominal organs incident to menstruation, a true biliary stasis set in, so that some of the bile was readily absorbed by the lymphatics and icterus developed. Probably most cases reported depend, said Dr. Bárdos, on a similar cause, though there are no other, excepting one —that of Metzger's) autopsy records.

Cancerous Growth and Radium.

Dr. Holzwarth presented two patients before the Society, one of whom had a cancerous ulcer at the inner angle of the right eye. The treatment began December, 1906, weekly sittings, duration one hour. The bromide of radium was used; improvement was noticed after every application. For some reason the patient discontinued treatment after six weeks, with the result that the condition became worse, and the edges of the ulcer, that were in a fair way of cicatrisation, re-opened again. Treatment was instituted again, with the result that the ulcer that resisted obstinately treatment for five years is now healed completely. The second case was that of a cancer of the breast for which the patient was operated on twice— nine and three years ago. In this case applications were made three times a week, and after 26 sittings the tumour seems to have disappeared, and the patient regained perfect control of shoulder-joint (tumour located under left clavicle).

Radiotherapy in Trachoma.

Dr. Waldmann investigated the basis of success obtained and described by Cohn, of Breslau, with radium in the treatment of trachoma. Waldmann has, in fact, found a theoretical basis for the explanation of the success, inasmuch as it is assured by several investigators that the beneficial effect of radium on malignant growths is due to its power to decompose the lecithin which forms a substantial element of these growths. As the granulations of trachoma also contain a certain percentage of this substance, the effect thereon of radium becomes intelligible. The author picked out seven trachomatous cases of a most pronounced character; the amount of radium used was at first 1 mg., and later 10 mg.; time of exposure, five to ten minutes. The tube containing the radium was simply applied over the area treated, and slowly moved about without touching the surface. The results were really astonishing. Five of the seven eyes were entirely cured; the other two are in a fair way of becoming so. The absorption of the granules was not accompanied by any untoward effect. The number of sittings varied from eight to fourteen.

LETTERS TO THE EDITOR.

THE REFERENDUM OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of The Medical Press and Circular.

Sir,—Judging from the quality of his writing, it is evident that your correspondent, "Festina Lente," is a leading man. I am sorry he did not deal with the main fact of my letter, which appeared in your paper of March 25th. I pointed out that out of a membership of over 20,000, not more than 1,978 recorded their votes on the momentous question referred to them, in spite of the fact that the issues involved were as important as "Festina Lente" indicates, and that this importance had been urged upon the members literally by every possible means during a period of many months. What hope is there for the Association or for the profession if the only body capable of speaking in the voice of every class of practitioner remains dumb to the most urgent call. The position of the profession as a body in relation with the State is deplorable. Medical law, the reform of which, as you have so often shown, is of infinitely greater consequence to the people than to practitioners, remains entirely confused and ineffectual and not the smallest improvement is possible until the political position of the profession is improved by its united efforts. The British Medical Association, I repeat, has developed into a mere co-operative society for the publication of a medical journal—a journal supplied to subscribers at a low price, but produced at an enormous cost. I doubt if 1 per cent. of the members are aware of the amount of the Association's income which is absorbed by the *Journal*. If they do not care about the issues decided by the Referendum, it is not likely they will take the trouble to scrutinise the annual balance-sheet.

I am, Sir, yours truly,
An Obscure Practitioner.

April 15th, 1908.

To the Editor of The Medical Press and Circular.

Sir,—Outside criticism should be always welcome. Occasionally what appears to be such is but the repetition of *ex parte* statements of the loud-voiced adherents of one view. Pardon my saying that there is just such a fallacy underlying the remark that the result of the Referendum shows the "revolt of the Association against the government of the Council." The fallacy is that the representative meeting represents the Association more accurately than does the Central Council. The voting on the Referendum, for good and all, explodes this idea. There is the absolute fact that only 9 per cent. have attended these meetings. And we could not with confidence assert that larger numbers attend the annual meetings, which elect to the Representative Meeting. On the other hand, the members of the Central Council are elected by an open franchise, and about 30 per cent. do vote.

There can be no question as to which gives the more accurate representation.

The Representative Meeting is noisy, and its proceedings are fully reported. Its mode of conducting business is the laughing-stock of sensible men, and needed columns of apology from its Chairman. This is the sort of thing:—"Adjournment carried by 48 to 34. The Chairman appealed to members not to go away, as they had only a bare quorum. Dr. So-and-So said"—and the discussion and voting go on, although the meeting is theoretically adjourned!

The proposals of the last Representative Meeting are proposals for disfranchisement, and are the most deadly contrivance towards handing over affairs to a headstrong clique and a fickle mob.

The Central Council, parliament, or cabinet, whatever it may be called, is elected, not septennially, nor triennially, but annually, in the most careful manner, and is therefore in the closest touch with the members.

One cannot get over the plain fact that what is boasted of as the voice of the Association is only the voice of 9 per cent.; in fact, as any member who has attended a divisional meeting knows, an even fainter voice. Of course, I am referring throughout to matters of administration, finance, etc. On purely professional matters the representatives fairly represent the feeling of the profession in their district. But the Referendum does not apply to these matters.

The reasoning of your correspondent, "Nil Desperandum," will not hold water, but there can be no disputing the facts and conclusions of your other correspondent, "An Obscure Practitioner." He is, perhaps, extreme in saying that members care "absolutely nothing," but that is what it will come to if we have funds thrown about and constant excitement over such hare-brained schemes.

I am, Sir, yours truly,
Anti-Syphon.
Kensington, April 16th, 1908.

CENTRAL MIDWIVES' BOARD.

To the Editor of The Medical Press and Circular.

Sir,—At page 432 of your issue of April 15th, "referring to instruction for midwives, Dr. Nepean Longridge suggested that they should possess *some* knowledge of the warning symptoms of uterine cancer."

Allow me to say that all those whom we have trained—and we commenced to train in 1880—have been taught the names and uses of all the midwifery instruments, and those gynæcologic instruments required in the out-patient department, and during their midwifery term of learning see all the out-patients, and learn how to use the required instruments. I need hardly say how much this gynæcologic opportunity adds to their interest in their work, takes away much of the drudgery, and renders them very valuable workers hereafter, especially if they be engaged abroad as missionaries, and stationed far away, it may be, from any medical man or woman.

I am, Sir, yours truly,
G. de Gorrequer Griffith.

LAW AND MEDICINE.

To the Editor of The Medical Press and Circular.

Sir,—Your utterances on the question of the attitude of the Bench in its various grades towards the medical profession are always admirable; it is to be hoped that they are not allowed to escape the notice of the men they immediately concern. Once more to-day you justly give voice to the indignation that the educated medical man must feel when he recognises the contempt with which science in general, and medical science and its votaries particularly, are looked upon by law officers of the highest responsibility; and when he recognises that the contempt is based upon pure ignorance of science, its methods and its achievements. We must be thankful, however, for small mercies. We must be thankful that, although a judge may be handicapped in the efficient exercise of his high office owing to ignorance of science, it is no longer possible that he should combine with ignorance, which is commonly his misfortune rather than his fault, intellectual inferiority rendering him entirely unfit for his lofty position. The days are, of course, gone by when a member of the Bar, whose early career had served only to demonstrate his intellectual unfitness for any responsible judicial position, could be made a Judge of the High Court by means of jobbery. The times have almost, if not quite, gone when a Judge, becoming incapable through age and mental decay, should be allowed to cling on to the detriment of his Majesty's lieges. If our Judges are too often devoid of scientific knowledge, it is not they, but our system of national education that is to blame. It is not more than forty years ago since the representatives of our ancient Universities would have almost crucified or burnt at the stake the men of science who seemed to threaten the foundations of their cherished beliefs. Many of us cannot have forgotten the memorable occasion at Oxford when Bishop Wilberforce made his attack upon the scientists; and the castigation which he received at the hands of Huxley. Since that day they have buried Darwin in Westminster Abbey, they have recognised science at the Universities, and some of them have organised scientific departments of magnificent amplitude. But, in spite of this, the great proportion of our schoolboys are still educated without any knowledge of science. Science is still looked down upon or despised by the great bulk of those students whose ambition is a position in Parliament, in the Law, in the Church, or otherwise in the service of the State. It is not only on the Bench that the lack of scientific knowledge shows itself conspicuously, and to the injury of the commonwealth—the medical quack is not the only fraudulent pretender whose apotheosis seems possible even at the opening of the twentieth century.

I am, Sir, yours truly,
April 15th, 1908. A Surrey Doctor.

MEDICAL FEES.

To the Editor of The Medical Press and Circular.

Sir,—The remarks of your correspondent *àpropos* of the recent notorious "dentist fees' " case in the law courts, deserve the careful attention of all medical men. Why should such extremes in the scale of remuneration be found in this alone of all the learned professions? The fact is that the fees demanded by surgeons and specialists are as absurdly disproportionate as those paid to club and open surgery medical men are disgracefully sordid and inadequate. Can we not get at the root of this unclean thing and purge it away from the body of an honourable profession?

The lawyers have no difficulty in enforcing a fair scale of fees. What is possible to the Incorporated Law Society should not be beyond the wit of the General Medical Council. It will be answered that the real point is the powers of the Council, which are inadequate. Then why, in the name of Heaven, does the Council not take steps to obtain adequate powers for protection? Are we to be through the rest of the ages at the mercy of a group of self-seeking corporations, who govern the Council, *inter alia*, and care not a jot for the general practitioner? Is the question of fees too mean a matter for this august Council to consider? Oh! for a whiff of the common-sense that created the Incorporated Law Society!

I am, Sir, yours truly,
A Man of Moderate Fees.
Brighton, April 14th, 1908.

AUSTRALIA FOR THE SONS OF PROFESSIONAL MEN.

To the Editor of The Medical Press and Circular.

Sir,—It is a good many years since I resided in Great Britain, but even then the problem of "what to do with our boys" pressed heavily upon the parents of the professional classes. The Army and Navy were closed to those who had no private income; the clerical, legal, medical and other professions were overstocked; and the openings in commerce were only for those who had money or influential connections. And everything that I can learn points to an intensification of these conditions at the present day. The position, therefore, of the man who has sons about to leave school must be a very difficult one, when he is face to face with the question of how to give them a satisfactory start in life. It is in the hope of being able to do something to answer this question which prompts me to beg for some space in your columns.

For years many of the sons of professional men have emigrated to the United States or Canada. I come forward with the claim that Australia and New Zealand can offer opportunities superior to either of these two countries to industrious and persevering lads, who are prepared to accept rough and strenuous conditions for the sake of obtaining a competence in later life. I may say at once that there are no openings in our large towns. All the city occupations are filled to overflowing. But the Australian Bush is calling for thousands of willing hearts and hands to subdue it and make it fruitful.

The wealth of Australia is immense, and this is mostly due to the production of wool, wheat, sugar, butter, live stock and fruit—commodities for which there is a great and growing demand at prices that are likely to be maintained or increased. Life on the land, therefore, promises to him who approaches it in a spirit both scientific and practical the opportunity, not only for a healthy and natural existence, but the possibility of an independence. The glorious climate of Australia is all in its favour. Here there is no long, rigorous winter, and there exists a voluntary organisation—the Immigration League of Australia—whose chief object is to welcome newcomers and afford them advice and assistance.

The Executive Committee are prepared to give information about Australia and New Zealand to all who write to them, to arrange for the placing of lads at agricultural colleges or farms, to act generally *in loco parentis* towards them, and to see that they are not taken advantage of in any way. The League numbers among its members some of the leading men of Australia, and their desire is to help in the development of the continent, and retain the British emigrant under the flag of Empire.

We say, send your sons to us, and we will ensure them proper treatment and a fair start. We do not want ne'er-do-wells or failures. Experience proves that such do no better here than in the Old Country. But steady, industrious lads are bound to succeed here, and in many cases their parents might be induced to follow them out here, and prolong their lives in this incomparable climate. We invite parents to communicate with us at Bull's Chambers, Moore Street, Sydney, Australia, and we will give them full information, and send books and maps about Australia and New Zealand, and prospectuses of agricultural colleges and schools of mines. Some months' notice is needed to enable a lad to be entered at an agricultural college.

I am, Sir, yours truly,
RICHARD ARTHUR, M.D.Ed.,
President, Immigration League of Australasia.

OBITUARY.

J. D. ROBERTS, M.R.C.S.ENG., L.R.C.P.I.

WE regret to record the death of Dr. J. D. Roberts, of Barnoldswick, a prominent figure in the Yorkshire district, which took place on April 14th. He went to Barnoldswick 44 years ago from Bradford, and built up an extensive medical practice in the district. He was for over 40 years Medical Officer, a position which he recently resigned, and was chairman of a local weaving company. His age was 73. The deceased gentleman qualified as M.R.C.S. (England) so far back as 1863, and as L.R.C.P. (Ireland) in 1879.

REVIEWS OF BOOKS.

YEAR-BOOK OF PHARMACY. (*a*)

THE space at our command would not allow of anything like an exhaustive review of the wealth of information brought together, classified, and arranged in a manner admirabily suited for reference in this excellent Year-Book.

Within the five hundred pages, not counting the forty odd occupied by the exhaustive index, the reader will find the cream of both the foreign and home journals that has any relevancy to the progress of chemistry, materia medica, and pharmacy, as far as these subjects influence therapeutics.

As an example of the value of the book to the medical practitioner, we may instance the abstracts from French and German journals on urine, and those on ergot and ergotinine.

In the section dealing with the proceedings of the conference, Mr. W. H. Martindale's paper on "Pharmacy in Foreign Countries" will well repay reading, and the author was justly complimented on his "infinite capacity for taking pains."

The volume is one of a long series of annuals which have done much to keep the pharmacian and the physician familiar with the advance of the collateral sciences to medicine and is fully equal to the best of its predecessors.

THE MAJOR SYMPTOMS OF HYSTERIA. (*a*)

IT is meant as no disparagement to our neighbours across the Channel when we say that the French have fuller and more abundant opportunities of studying hysteria than those who practise among the phlegmatic Anglo-Saxons. The Gallic temperament, with its brightness, its volatility, and its enthusiasm, lends itself more readily a prey to the development of hysteria than does the matter-of-fact mentality of the true-born Briton. The best studies of the disease, at any rate, have been produced by French physicians, and in the line of Charcot and Luys comes Professor Janet, who contributes the chatty, interesting, and suggestive work before us. This book is really a republication of a series of fifteen lectures delivered before the Medical School of Harvard University on the occasion of the inauguration of its new buildings in 1906, and we warmly congratulate the author on having given to his subject a new and convincing turn. Professor Janet's definition of hysteria is one which it would be difficult to improve, and for the sake of those who do not know it, we give it here:—"Hysteria," he says, "is a form of mental depression characterised by the retraction of the field of personal consciousness and a tendency to the dissociation and emancipation of the systems of ideas and functions that constitute personality." There we have the basis on which these charming lectures are built up, and we cordially invite all who are interested in the subject to give themselves the pleasure of reading them in their leisure moments, however scant.

SCHROTTER'S HYGIENE OF THE LUNG. (*b*)

THE object of this little book is to instruct the layman on the functions of the respiratory organs and on the importance which a free exercise of these functions possesses for the human organism. The subject matter is divided into three parts. The first deals very fully with the structure and functional activity of the lungs, the second with the care of the healthy lung, while the third is devoted to the consideration of pulmonary diseases. The book appeals, of course, to the educated reader, and in fact contains much that is of value to the medical man. The translation has been faithfully carried out, the author's meaning being in all cases accurately represented. A comparison with the original text at once proves this to be so. The illustrations have also been well reproduced, and add not a little to the value of a very useful and practical volume.

DURING the week ending April 11th there have been two deaths from plague at Accra and one at Dodowah. All other places have been free of plague.

(*a*) "Year-Book of Pharmacy from July 1st, 1906, to June 30th, 1907." With the Transactions of the British Pharmaceutical Conference at the Forty-fourth Annual Meeting held in Manchester, July, 1907. Editor of the Year-Book, J. O. Braithwaite. Editor of the Transactions, E. Saville Peck, M.A., Edmund Whyte, B.Sc., F.I.C. London: J. and A. Churchill. 1907.

(*a*) "The Major Symptoms of Hysteria." By Pierre Janet, M.D., Professor of Psychology in the College de France. New York: The Macmillan Co. London; Macmillan and Co., Ltd. 1907.

(*b*) "Hygiene of the Lung in Health and Disease." By Professor Dr. Leopold von Schrötter, Director of the Third Medical Clinic of the Vienna University. Translated by H. W. Arnutt, M.R.C.S., L.R.C.P., with 16 illustrations. London: Redman, Ltd.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for The Medical Press and Circular.

RECENT MEDICAL LITERATURE.

Milroy's Disease.—Hope and French give an account of a family, several members of which were affected by a persistent hereditary œdema with acute exacerbations, a condition to which they propose to give the name "Milroy's Disease," after the name of the writer who first called attention to it (*Quarterly Medical Journal*, April, 1908, p. 312). The condition had first manifested itself in a male, five generations back, and had been or is present in thirteen members out of forty-two individuals comprising the five generations, and an account of whom could be obtained. Both males and females were amongst those who suffered, and it was noticeable that epilepsy and mental trouble was found amongst some of those members who escaped the hereditary complaint. The point in which the present cases resembles those previously described are given as follows, the summary forming a convenient account of the chief features of the disease:—(1) The œdema was restricted to the legs, and there was no traceable cause for it, general or local. (2) There was an absence of all pain in the pale swollen legs, and also a total absence of constitutional symptoms. (3) The strong family predisposition, with incidence in both males and females. (4) The œdema was very sharply limited at its upper level. (5) The œdema remained permanent from its first appearance. The writers' cases, however, differed from others in the occurrence of acute attacks accompanied by pain and increase of swelling. In none of them, moreover, was the œdema present at birth. The cause of the condition is discussed, but no satisfactory conclusion is arrived at, the authors leaning to the view that it is a vaso-motor neurosis and allied to such diseases as factitious urticaria and angio-neurotic œdema. M.

Cutaneous Diphtheria Reaction.—Schick (*Munch. Med. Woch.*, 1908, No. 10) has produced by inoculation of a diphtheria-toxin solution a cutaneous reaction somewhat similar to the tubercular cutaneous reaction, or more frequently a local pus vesicle. The reaction is specific and does not take place when toxin is ingested which has been previously neutralised in vitro by anti-toxin. Nor does it occur when a dose of anti-toxin of from 1,500-3,000 units has been given about 24 hours previous to the inoculation. As far as diagnosis is concerned the re-action is of little use, but the author hopes by accurate observation to arrive at new knowledge concerning the clinical course of diphtheria, and more especially to be led to a rational method of estimating the dosage of anti-toxin required in any particular case. M.

Pulmonary Complications following Anæsthesia.—Wright discusses this subject in the *Johns Hopkins Hospital Bulletin* (March, 1908, p. 89). Out of 9,000 patients anæsthetised in the gynæcological service of the Johns Hopkins Hospital prior to August, 1903, 29 patients developed pneumonia, and of these six died. From an analysis of the cases it seems likely that the duration of the anæsthesia is a most important factor in the production of post-anæsthetic pneumonia, as only four out of the 29 had been under the anæsthetic for less than an hour. Out of the 29 cases, 12 were diagnosed as lobar, and 17 as broncho-pneumonia. The lobar variety differs from lobar pneumonia seen in the medical wards as follows:—(1) The temperature as a rule is lower, and the curve shows more irregularities. (2) The duration is shorter, and there is rarely a true crisis. (3) Complications are rare. (4) Cough is not severe and the sputum is rarely blood-stained. (5) The pneumonia is often central, and physical signs develop late. The second or third day after operation is the common time for the development of symptoms. Other pulmonary complication met with are bronchitis, pulmonary abscess, lung emboli, serous pleurisy, and empyema. The causation of these various conditions is unknown, but most probably a combination of some of the following factors are operative:—(1) Irritant action of anæsthetic; (2) aspiration of mucus and vomit, and hypersecretion of mucus; (3) emboli; (4) extension of infection through sub-diaphragmatic space in cases of laparotomy; (5) limitation of lung expansion and lessened resistance of patient. M.

Action of Choline on Arterial Pressure.—Desgrez and Chevalier (*Compt. Rend.*, tome 146, p. 89) point out that choline injected intravenously in dogs, in a proportion of 5 milligrammes per kilo body weight, causes a fall of blood pressure up to 5 c.m. Hg. This first condition is soon passed, however, and is followed by a longer period lasting some hours, during which there is a diminution of pressure. Choline acts also as a direct antagonist to adrenalin, and it is possible to combine the two substances in such proportion that the effect of each on blood pressure is completely annulled. Choline is up to this the only substance normally present in the animal body of known chemical constitution which causes a fall in blood pressure. M.

Arterio-Sclerosis in Relation to Mental Disease.—Campbell ((*Amer. Journ. of Insanity*, January, 1908) states that though this condition is common among mental patients in advanced life, and often appears to be of little importance, yet there are some cases where it seems to be the central element in the clinical and anatomical picture. He divides the cases of mental disorder based on cerebral arterio-sclerosis into two main groups. In the first group the symptoms are less severe and more stationary, while the second group includes those more severe and progressive cases with a varied neurological picture and extreme reduction of mental activity. Certain cases described as melancholia, hypochondria, and neurasthenia can be better grouped on ætiological grounds as cases of arterio-sclerotic brain disorder, while in certain cases of dementia the arterio-sclerotic changes are obviously the most important element in the process. Campbell further suggests that "in certain cases of epilepsy with onset in late life, the convulsions and general symptomatology are closely related to arterio-sclerosis.

K.

Atoxyl in Syphilis.—Ward (*R.A.M.C. Journ.*, April, 1908) records the results of the treatment of syphilitic patients with this drug. The efficacy of this drug in the treatment of sleeping sickness suggested its trial in the case of syphilis, though various writers have described the gravest symptoms and consequences following the administration of the drug. Atoxyl is a proprietary word used to denote the special preparation of a German firm of manufacturers, but many preparations have been put on the market manufactured according to the chemical analysis. Ward suggests that the difference in the results obtained by different workers may be explained by a difference in these various preparations. The drug used in the cases under notice was that manufactured by Burroughs Wellcome and Co., and is described as "Sodium-para-amino-phenyl-arsonate," and in no case was any toxic symptom seen as a result of the treatment. When starting the treatment the drug was administered intramuscularly in doses of 6 grains every alternate day till the patient had received between 50 and 60 grains, but in the latter cases the dose was increased to 9 grains through a course of eight to ten injections. In all the cases the treatment was quickly followed by a disappearance of the symptoms, and this was especially marked in the cases of the lesions on the mucous surfaces. In the majority of the cases a period of eight to ten weeks elapsed before the patient returned with any active signs of the disease, which were, however, very slight and easily yielded to a second course of injections of 6 grains each. How many courses of injections are necessary to completely stamp out the disease, or how far the dose may safely be increased are points which are not yet settled, but there is sufficient evidence to show that the drug is a very valuable agent in the treatment of syphilis. Ward says "its immediate action on the lesions of early syphilis would appear to be quite equal to, if not better than, that of mercury." The drug is readily soluble in hot distilled water, and the injections are absolutely painless. Injection of the drug is never followed by salivation or spongy gums, and it appears to have a tonic and alterative effect. K.

Congenital Biliary Cirrhosis.—Griffith (*Archives of Pediatrics*, March, 1908) records a case of this rare condition. The child was admitted to hospital at the age of five months, and had, the parents stated, been jaundiced since birth. He had been under treatment for some time before admission to hospital, and though the jaundice had not varied the child's weight was stated, for a time to have increased. On admission to hospital the child was found to be deeply jaundiced and to have several purpuric spots on the scalp, the urine contained bile pigment, and the stools some dark material, apparently altered blood. The child died five weeks later, having continuously lost weight during his stay in hospital, in spite of the fact that there was no diarrhœa and food was well taken and retained. On post-mortem examination the liver and spleen were both found considerably enlarged. The gall-bladder was empty and collapsed, and the cystic duct completely obliterated. The right and left hepatic ducts were patulous, but as a partial examination only was permitted it was impossible to trace the common bile duct. Microscopical examination showed the typical lesions of biliary cirrhosis, there being an extensive increase of the periportal connective tissue with a proportionately great multiplication of bile ducts. "The hyperplastic connective tissue in some instances invaded the lobule, but was in general confined to the periphery. In the centre of the lobule there was some deposit of fibrous tissue of a younger and more cellular type." There was no evidence of congenital syphilis in the case. K.

Treatment of Chorea.—Koplik (*Med. Record*, February, 1908) considers the treatment of chorea minor, and lays great stress on the dangers of the indiscriminate use of Fowler's solution. He finds that it is the rule for patients treated with this drug to have albumin in the urine. Casts, and even blood, may be found. He finds that albumin appears before any other sign of toxic action of the drug, and should be the signal for stopping further use of it. He shows that Fowler's solution, on standing, becomes stronger, so that what is supposed to be a small dose of the drug is in reality a large one. Cases do as well without use of Fowler's solution. The treatment he recommends is modified rest cure, with some mild sedative, as trional, and, where needed, strychnine as a tonic. Hydrotherapy is always useful. Sodium salicylate may be tried, but should not be continued if not well borne. Digitalis should not be used. He believes that isolation and darkened rooms are not indicated, as children do much better with quiet companionship and fresh air. D.

Contribution to our Knowledge of Hyperacidity.—Balas (*Deut. Med. Woch.*, 1908) reports three cases of persistent uncomplicated hyperacidity of the stomach cured by gastro-enterostomy. In none of these three cases was there any evidence of stenosis of the pylorus or of ulcer. These results coincide with the Katzenstein theory that bile and pancreas secretion regurgitating into the stomach reduce the acidity through neutralisation, also through inhibition of the gastric secretion. Both these secretions were found in the stomachs of these three cases after operation. D.

Epidemic Poliomyelitis.—Sinkler (*Arch. of Diagnosis*, New York, 1908) produces an analysis of 274 additional cases, making a total of 509 with those already reported, which tend to support his conclusion (*Amer. Jour. Med. Sciences*, April, 1875) that a large majority of cases of poliomyelitis occurs during the summer months. In his series of 509, 418, or 82 per cent., occurred between June and October. The nature and progress of the disease indicate that it is clearly due to infection by a micro-organism developed during hot weather, and he refers to the fact that in an epidemic in Vermont in 1894 horses and birds were also affected. D.

Simplified Serum Differentiation of Syphilis.—Klausner (*Wien. Klin. Woch.*, February, 1908) announces that he has obtained constantly positive results in 31 cases of syphilis, and constantly negative results in 23 cases of non-syphilitic cutaneous affections with the simple diagnostic test he proposes. In a glass, 0.5 cm. in diameter, and 7 cm. tall, he mixes 0.2 c.c. of the patient's serum with 0.7 c.c. of distilled water. After thorough mixing, the glass is set aside at room temperature. In the course of about 15 hours a precipitate forms, in the syphilitic cases, from 2 to 4 mm. in depth, or flakes float in the fluid, gradually sinking to the bottom. The control glasses show no precipitation during this period. If a little precipitation occurs by the end of 24 hours, it is insignificant compared with the marked amount in the syphilitic serum. As the precipitate dissolves in physiologic salt solution and in acetic acid, he believes it to be formed of globulin, and that it may possibly prove to be characteristic of all processes accompanied by formation of anti-bodies. The reaction was positive also in 2 cases of severe croupous pneumonia and in 1 of typhoid, but by diluting the serum to 1 to 5, or 1 to 10, there was no further reaction in these cases, while the reaction occurred unmodified even with this dilution in the cases of syphilis. D.

Reduction of Ingestion of Fluids in Kidney Disease.—Widal (*Bull. de l'Acad. de Méd.*, Paris February, 1908) regards the scales as a most important aid in the treatment of patients with infiltration of the tissues. Systematic weighing not only informs the physician in regard to the visible œdema and its extent, but it reveals accumulation of fluid long before it becomes apparent externally. The fluctuation in the weight shows the necessity for supervision of the intake of fluids, and this is imperative, he thinks, in every case of interstitial nephritis, whether there is appreciable œdema or not. As a rule the patient can take care of two quarts of fluid, but in some cases he does much better if the amount ingested is reduced to three pints, or even one quart in the 24 hours. The diuresis has no significance unless it can be compared with the amount of fluids ingested. Restriction of the intake may prove useful in prophylaxis of further trouble in nephritis, and also in the course of cardiac affections with impending asystole. Even with adequate compensation the physician should never neglect the supervision of the amount of fluids to be allowed the patient. D.

MEDICAL NEWS IN BRIEF

Diphtheria in Schools.

AT a provincial sessional meeting of the Royal Sanitary Institute, held a few days since in Hull Town Hall, Dr. J. Wright Mason read a paper on "Diphtheria in Elementary Schools, and its Prevention." Having remarked that diphtheria is particularly a disease of the young, occurring principally between the ages of two and eight years, Dr. Mason said in the first years of life boys are more liable to die from the disease. This risk diminishes year by year, and in the third and fourth year it is transferred to the female side.

The greatest attack rate is generally between four and five years, children under one year being remarkably exempt, due possibly to their sleeping with their parents instead of with children. "There is no doubt," Dr. Mason added, "that school life plays an important part in the spread of diphtheria, and is also a factor in the increasing prevalence of the disease amongst our urban population. At the present time there is a large number of children under five years of age receiving instruction in elementary subjects, when the brain is not sufficiently developed to benefit by it. It has been stated that some £1,250,000 is annually expended on this unnecessary and, to my mind, educationally useless attendance."

Royal College of Surgeons of England.—The Admission of Women.

We are requested by the Secretary of the Royal College of Surgeons to publish the following:—

The President has been informed that an unauthorised circular is about to be issued to members of the College regarding the admission of women to the membership and fellowship, and that in this circular it is suggested that members should disregard the request of the Council that the answers to the questions in the official circular should be in the form of simply "Yes" or "No." It is hoped that members will not allow themselves to be misled by this unofficial circular, and that, with a view to avoiding confusion as regards the result of the poll, they will record their answers on the official balloting card in accordance with the instructions for voting contained thereon.

Infants' Health Exhibition.

The Council of the Incorporated Institute of Hygiene have decided to promote a special exhibition, illustrating the requirements of infant life and the care and health of children, which will be opened, under distinguished auspices, on June 15th. This exhibition is intended to demonstrate the progress of recent years in providing for the welfare, comfort and training of the child, and it is proposed to exhibit the latest improvements connected therewith. An attractive display is being organised, which will appeal strongly to mothers and the heads of families, as well as to members of the medical profession, matrons and nurses, while it will have special interest to school teachers, as the recent Act for the medical inspection of school children has drawn much attention to this important subject.

The King and Dr. Hall Edwards.

The following letter has been received by Mrs. Hall Edwards from the King, in reply to a letter of thanks which she wrote to his Majesty in acknowledgment of the pension granted to her husband from the Civil List.

"Biarritz, April 1st, 1908.

"Dear Madam,—I am commanded by the King to thank you for your letter, and to say that it has given his Majesty sincere pleasure to confer a Civil List pension upon your husband, whose services have been so extraordinarily self-sacrificing towards the advancement of science and the benefit of humanity. The King wishes you to express to your husband his deepest sympathy with him, together with the earnest hope that possibly his other hand may yet be saved.

"I remain, dear Madam, yours very faithfully,
"Arthur Davidson."

Queen's College, Belfast.—List of Prizewinners.

The following have been awarded prizes at the class examinations in medicine lately held:—Chemistry.—J. H. Beverland, H. M'Ilroy. Practical Chemistry.—Senior: Adam Anderson; Junior: Joseph Porter, Frederick W. M'K. Thomson, Robert M. Beath, B.A. Chemical Laboratory.—Kenneth C. G. Arbuthnot, Frances E. Blair. Anatomy.—Senior: William W. D. Thomson, William A. Berry, Robert A. Kerr, Harold Black. Junior: Thomas D. Graham, Frederick Crooks. Practical Anatomy.—Senior: Robert A. Kerr, William W. D. Thomson, Charles J. Simpson, Harold Black, Henry P. Malcolm, William O. Wilson, B.A. Second Year: William A. Berry, Robert J. M'Connell, William K. Calwell. First Year: Frederick Crooks, Thomas D. Graham. Physiology.—Senior: William A. Berry (Harold Black and Robert A. Kerr equal), Melville C. Irwin. Junior: Robert J. M'Connell, Thomas D. Graham, William M. O'Farrell, William M'M. Millar. Practical Physiology.—Charles J. Simpson, Robert A. Kerr (Harold Black and Frederick O. Clarke equal). Practical Histology.—William Wilson, (Norman B. Graham, B.A., and Robert J. M'Connell equal). Special Prize for Histology Demonstrations.—Charles J. Simpson, George Cooper. Materia Medica.—(Harold Black and Samuel E. A. Acheson equal), Melville C. Irwin, William A. Anderson. Special Mid-Session Prizes.—Harold Black, Samuel Edwin A. Acheson, William F. Algeo. Medicine.—Senior: (David S. Clarke, B.A., and Caroline J. Crawford equal), Caroline V. Lowe. Junior: William W. D. Thomson, Harold Black, William A. Anderson. Midwifery, Gynæcology, and Diseases of Children.—Alexander Patton, B.A., William Dickey (Alexander V. Craig and John James Gilmore equal). Surgery.—John James Gilmore, Alexander V. Craig, William Dickey. Ophthalmology and Otology.—John J. Gilmore (William Dickey and Alexander V. Craig equal). Sanitary Science.—Alexander V. Craig, John J. Gilmore.

PASS LISTS.

University of Durham Faculty of Medicine.

The following Degrees have been conferred during April, 1908:—

Doctor in Medicine.—James G. Gibb, M.B., B.S., Durh.; Sampson G. V. Harris, M.B., B.S., Durh.; Arthur H. Nott, M.B., Durh. (*in absentia*); John C. Pearce, M.B., B.S., Durh.; William T. Sewell, M.B., B.S., Durh.; Edward Tate, M.B., B.S., Durh.

Doctor in Medicine for Practitioners of Fifteen Years' Standing.—David Donald, L.R.C.P. and S., L.F.P.S., G.; B. W. N. Gowring, M.R.C.S., L.R.C.P.; Robert Hudson, L.M.R.C.P. and S., I.; Walter W. Nuttall, M.R.C.S., L.R.C.P.; Robert G. Reid, L.R.C.P. and S., L.F.P.S., G.

Master in Surgery (M.S.).—James G. Gibb, M.B., B.S., Durh., M.R.C.S.

Bachelor in Medicine (M.B.) and in Surgery (B.S.).—Ronald M. Davies, Helen M. Gurney, Arthur H. Hogg, Ernest L. Markham, Gertrude E. O'Brien, Charlotte Purnell, Elizabeth Patteson, Hubert Shield, Eric F. Waddington, Leslie H. Walker, James B. Williamson, John F. Young.

Bachelor in Hygiene (B.Hy.).—Robert Samuel Trotter, M.D., Aber.

And the following received the Diploma in Public Health (D.P.H.).—Samuel T. Cochrane, M.B., B.S., Durh.; Lilian M. Chesney, M.B., Ch.B., Ed.; Edward G. Dru Drury, M.D., B.S., Lond.; George P. Harlan, M.D., Ch.B., Glas.; Robert S. Trotter, M.D., Aber.

University of Aberdeen.

At the Graduation ceremonial on April 7th, 1908, the following degrees were conferred:—

Degree of Doctor of Medicine (M.D.).—William F. Croll, M.A., M.B., Ch.B. (with Honours); William S. Garden, M.B., Ch.B.; James Robertson, M.B., Ch.B.; Lieut.-Colonel Henry Thomson, M.B., C.M., I.M.S., Sanitary Commissioner for Madras, India.

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—James Watt, M.A. (with First Class Honours); Thomas C. Boyd, M.A. (with Second Class Honours).

Ordinary Degree.—John Anderson, Alex. A. Bisset, John Brown, Donald Buchanan, James B. Cruickshank, James G. Danson, George C. Davidson, Adam Gilchrist, James A. Hendry, M.A., B.Sc.; Edward Johnson, James W. Littlejohn, Wm. G. Macdonald, James D. Mackay, John F. Macleod, Rae McRae, Allan Massey, William Mearns, Arthur J. Milne, Thomas B. Nicholls, Ian Ogilvie, Arthur W. Pirie, Douglas Porter, John Rennie, Robert Ross, Andrew J. Shinnie, William A. Watson. Wm. G. Watt, Maurice J. Williamson, Douglas Wood.

Diploma in Public Health.—William Begg, M.B., Ch.B. (Aberd.); John H. Moir, M.B., Ch.B. (Aberd.); George Scott, M.B., C.M. (Aberd.), Lt.-Col. late R.A.M.C.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

OMEGA.—Our correspondent is thanked for his communication. We have dealt with it editorially elsewhere.

VACCINE STATISTICAL TABLES.

WE have been asked by the Association for the Supply of Pure Vaccine Lymph, the well-known agents of Dr. Warlomont's calf vaccine, to insert a note as to their published statistics. For the March quarter of 1908 402 insertions have been made, with the satisfactory result of 367 typical first-rate and 35 secondary vesicles. Lest there should be any misconception as to the exact meaning of the 35 secondary vesicles, we are informed that two were accidental, there being two cases producing two typical and one secondary vesicles. The 33 remaining were produced from 11 cases of three insertions each by the same operator, using similar vaccine, and on a similar occasion. It is tolerably certain that the failure to develop first-rate vesicles in these 11 cases must have been due to a difference in personal susceptibility. In view of the long-established excellence of Dr. Warlomont's vaccine, we are pleased to explain what may at first sight appear to be a slight deficiency, but is, in reality, a high testimony to the trustworthiness of the vaccine.

B. C. (Woking).—The newspaper report has reached us from another source, and has been placed in the hands of our staff.

A SUFFRAGETTE CLINIC.

AN establishment has been set up in Berlin for a clinic conducted entirely by female doctors. The work of female doctors has been carried on hitherto under difficulties, though upwards of 200 operations are performed annually entirely by women. The new clinic, which is the result of persistent efforts, chiefly of Fraeuleins Franciska and Henriette Tiburtius, the former a doctor of medicine and the latter a doctor of dentistry, will be a kind of private hospital, where any Berlin woman doctor may bring her patients and treat them, and, if necessary, perform operations on them.

BRISTOLIAN.—If our correspondent will refer to our issue of February 26, 1908, he will find that the subject is discussed in our editorial columns.

Meetings of the Societies, Lectures, &c

WEDNESDAY, APRIL 22ND.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Diseases of the Skin (Dr. Meachen); Diseases of the Eye (Mr. Brooks).

THURSDAY, APRIL 23RD.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital Tottenham, N.).—2.30 p.m.: Medical Out-Patient Clinic (Dr. Whiting); X-Rays (Dr. Pirie).

FRIDAY, APRIL 24TH.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Operations. Medical Out-Patient Clinic (Dr. Auld): Diseases of the Eye (Mr. Brooks): 3 p.m.: Medical In-Patient Clinic (Dr. Leslie).

ROYAL SOCIETY OF MEDICINE (20, Hanover Square, W.—Electro-Therapeutical Section (Hon. Secretary: Reginald Morton): at 8.30 p.m. Paper: Dr. Reginald Morton: The Electrical Treatment of Atonic Conditions of the Digestive System.

Appointments.

DOMINY, GEORGE HERBERT, L.R.C.P.Lond., M.R.C.S., District Medical Officer by the Blandford (Dorset) Union.

FOTHERGILL, W. E., M.A., B.Sc., M.D., Honorary Assistant Gynæcological Surgeon to the Manchester Royal Infirmary.

HOLLANDER, BERNARD, M.D., M.R.C.S., L.R.C.P.Lond., Physician to the British Hospital for Mental Disorders and Brain Diseases, Camden Road, N.W.

JAMES, A. M. A., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Kingscliffe District of the County of Northampton.

LAWSON, J. WARD, M.R.C.S., L.R.C.P.Lond., Physician to the British Hospital for Mental Disorders and Brain Diseases, Camden Road, N.W.

MANSON, KENRED, M.B., B.S.Dunelm, House Physician to the Royal South Hants and Southampton Hospital.

NICHOLLS, A. R., M.R.C.S., L.R.C.P.Lond., Assistant Medical Inspector of Schools for the Langport District of Somerset.

PARSONS, J. F., M.R.C.S., L.S.A., Assistant Medical Inspector of Schools for the Frome District of Somerset.

POLLARD, G. S., M.R.C.S., L.R.C.P.Lond., Assistant Medical Inspector of Schools for the Frome District of Somerset.

SHIPWAY, F. E., M.D., B.C.Cantab., Honorary Anæsthetist to Guy's Hospital.

THOMAS, FRANK LESLIE, M.B., B.S.Lond., L.R.C.P.Lond., M.R.C.S., District Medical Officer and Medical Officer to the Workhouse by the Barnstaple (Devon) Board of Guardians.

WALTER, R. H., M.B., M.S.Edin., has been appointed Assistant Medical Inspector of Schools for the Yeovil District of Somerset.

WILLIAMS, CHISHOLM, F.R.C.S.Edin., M.R.C.S.Eng., L.R.C.P. Lond., L.S.A.Lond., Medical Officer to the X-Ray Department at St. John's Hospital for Diseases of the Skin, Leicester Square, London.

Vacancies.

Borough of Bootle.—Hospital for Infectious Diseases.—Resident Medical Officer. Salary, £120 per annum, with board, washing, and apartments at the Hospital. Applications to the Chairman of the Health Committee, Town Hall, Bootle.

Borough of Southend-on-Sea.—Medical Officer of Health. Salary, £550 per annum. Applications to William H. Snow, Town Clerk, Southend-on-Sea.

County Borough of Preston.—Schools Medical Officer. Salary, £250 per annum. Applications to Alfred Howarth, Town Clerk, Town Hall, Preston.

Nottingham City Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, etc. Applications to the Medical Superintendent.

Prince of Wales General Hospital.—House Surgeon, Salary £75 per annum; House Physician, Salary £75 per annum; Junior House Surgeon, Salary £40 per annum; Junior House Physician, Salary £40 per annum. Each appointment with residence, board and laundry. Immediate application to Fredk. W. Drewett, Director. (See Advt.)

Staffordshire County Asylum at Stafford.—Second Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and attendance. Applications to the Medical Superintendent.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Physician for six months. Salary, £20, washing allowance £2 10s., with board and residence in the Hospital. Applications addressed to the Secretary. (See Advt.)

Births.

NICOLL.—On April 17th, at 22, Abingdon Villas, Kensington, the wife of Charles Vere Nicoll, M.R.C.S., L.R.C.P.Lond., of the above address and Iverna Court, W.—a son.

QUIRKE.—On April 10th, at 308, Lillie Road, S.W., the wife of John J. Quirke, M.R.C.S., L.R.C.P., of a son.

WALKER.—On April 14th, at 35, Westgate, Peterborough, the wife of R. Alec Walker, M.B., F.R.C.S., of a son.

Marriages.

CARRICK—MURRAY.—On April 15th, at the United Free Church, Sanquhar, Peter Carrick, M.A., M.B., Ch.B., of Blackheath, London, to Kathleen Macintyre, eldest daughter of William Murray, J.P., Agent British Linen Bank, Sanquhar.

MACKAY—CROMMELIN BROWN.—By Spanish Law, at Huelva, Spain (the domicile of the bridegroom), and afterwards, on the 13th April, at the Langham Hotel, London, by the Rev. David Macdonald, B.D., of Manchester, William Alexander Mackay, F.R.C.S., and M.D.Edin., to Louisa Emily Crommelin Brown, daughter of the late John Crommelin Brown, of the Indian Civil Service.

Deaths.

KNOX.—On April 15th, at his residence, Summerhill, Kingstown, Francis Blake Knox, L.R.C.S.I., L.K.Q.C.T.I., son of the late Captain F. Blake Knox, 5th Dragoon Guards.

PECHEY-PHIPSON.—On April 14th, at 29, Grimston Gardens, Folkestone, Mary Edith Pechey-Phipson, M.D., formerly Chief Physician of the Cama and Allbless Hospitals, Bombay, wife of Herbert M. Phipson.

RUSSELL.—On April 15th, at 17, Canynge Road, Clifton, Elizabeth Mary, widow of the late John Russell, M.R.C.S., of Clifton, Bristol, aged 77 years.

SPICER.—On April 15th, at Granada, Spain, Florence, the beloved wife of W. T. Holmes Spicer, F.R.C.S., 5, Wimpole Street, London.

WALKER.—On April 13th (midnight), at Wolverton, Beckenham, Joseph Walker, M.D., M.R.C.S.Eng., L.D.S., late of 22, Grosvenor Street, London, W., in his 83rd year

"Formolyptol"

ITS

BACTERIOLOGY

The crucial test of the efficacy of an antiseptic fluid is the bacteriological one. When we state that FORMOLYPTOL is equal in germicidal potency to a 1-1000 solution of Corrosive Sublimate, without the irritant or toxic properties of the latter drug, we base our claim upon the results of careful laboratory experimentation with the different varieties of germ life. Complete and conclusive reports from prominent bacteriologists sent upon request.

ANDRUS & ANDRUS
46 Holborn Viaduct, London, E. C.
Representing
THE PALISADE M'F'G CO., New York

FORMOLYPTOL is a palatable, fragrant and slightly astringent formaldehyde preparation. It does not stain linen or clothes. Employed in Gynecology and Obstetrics, Rhino-Laryngology, Surgery and Dentistry. Also internally in the treatment of Typhoid Fever, and in the gastro-intestinal disorders of children.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXVI. WEDNESDAY, APRIL 29, 1908. No. 18.

NOTES AND COMMENTS.

Criminal Prosecution and Unqualified Practice.

AT the risk, we fear, of wearying our readers, we have contended over and over again that, even with the present laws, a vigorous administration can do much to prevent fraudulent quackery, and we have lamented with almost tiresome iteration the supineness of the Treasury and chief constables in following up and prosecuting charlatans. The well-known Brighton case showed how easily possible it is to get these rogues punished if a well-worked-up and well-directed case be presented at assizes. Last week another prosecution on similar lines was undertaken. A man named Mortimer, who, it is alleged, has been practising in Exeter under the style of "Dr. Mortimer, U.S.A., Medical Specialist," was charged with fraudulently obtaining sums of money varying from £1 12s. to £4 from various persons. Counsel, in opening the case, said the people defrauded were of the poorest class of society, who, on account of illness, had been ready to listen to any quack who promised them relief. It appeared that Mortimer issued a bill which was circulated in the town, describing himself as "The Great American Doctor, Prof. Mortimer (Berkeley College, Boston, U.S.A.)," and detailing how he had "devoted a life-time study of every disease that affects and afflicts humanity," and had "equipped himself with every modern appliance for the diagnosing of every disease in existence." This bill went on to state, among much of a similar character, that "Prof. Mortimer wishes it to be known that he has no patent cure-alls to sell—no quackery, but offers you the advice of a renowned medical specialist."

The Fine Line.

IN outlining the prisoner's offence, counsel said that the plan adopted was the same with all patients, namely, first to frighten them and then to allay their fears by saying he would work a cure, always insisting on having cash down before the treatment was begun. A guarantee was given that the money would be refunded if the desired effect was not produced, but the prisoner only seems to have stayed a fortnight in the town. Some of the medicine was analysed and found to consist principally of water with a little colouring matter and sal volatile. At the hearing the first case broke down, but a number of others were proceeded with, and evidence was given by a detective from Swansea to the effect that the prisoner had practised in that town as a "medical specialist" for three weeks, and stood committed on similar charges for offences perpetrated in that town. The defence raised by the prisoner was to the effect that any man could practice medicine and surgery in England, and that his treatment was legitimate and *bonâ fide*. He hoped to bring witnesses on his behalf, failing which the Recorder said he would commit him for trial. At this stage of the case we are precluded from comment, but we cannot but express our pleasure that the police authorities are setting to work on these cases of unqualified practitioners, as such proceedings are manifestly in the public interest, if only for their educative influence.

Stiffening of the Brain.

DR. FREYBERGER continues the pathologist of election in South-West London, and we await the day when he will be placarded in the papers as "the celebrated specialist," or on the lines which the journals, by common consent, have adopted with regard to Mr. Pepper, "the famous expert, Professor Freyberger." But whether specialist or not, Dr. Freyberger's word passes apparently for gospel with the coroners who delight in his evidence. At Lambeth, last week, an inquest was held on a 17-months' baby who had died at St. Thomas's Hospital soon after the operation of trephining. The hospital pathologists were, presumably, considered incompetent to do the work which it is their life's business to do, namely, to give an expert opinion on the cause of death, and so Dr. Freyberger was resorted to. This gentleman said that he found the left side of the brain smaller than the right; the brain substance very stiff, resembling a cheesy substance; whilst in the cavities were hard nodules. On the right side some of these had run together into a hard, gristly mass. "Death," he continued, "was due to shock following the operation whilst the child was suffering from stiffening of the brain." To him said the Coroner: "Is this disease you have described common?" "No," answered Dr. Freyberger, "very rare." Here at last we are on common ground with Dr. Freyberger; "stiffening of the brain," in our experience, or in his, is certainly rare. But one cannot help the reflection whether it is worth while to get a gentleman from Regent's Park to Lambeth to say so.

Dr. Kerr and Medical Inspection.

WHEN Dr. Kerr speaks on school hygiene he reminds us of the trout among the minnows. With all due deference to medical officers of health and philanthropic people who are interested in children, the administration of the new Act should be, and can only effectively be, carried out by persons of certain qualifications, and however advantageous a knowledge of sanitary conditions may be, public health accomplishments, in the ordinarily-accepted sense of the term, do not necessarily connote any fitness at all for the inspection of children. At the recent conference of the National Association of Teachers, Dr. Kerr read a paper on "The Medical Inspection and Treatment of Children," in which he showed up the impracticability of many of the arrangements which are being rushed into by the authorities of one kind and another. "Medical inspection," he said, "was not the weighing and measuring of every child in England. That would be pure waste of money, without use educationally or medically . . . . and the recording of most childish complaints was not worth the trouble." These are very wise words which we are glad to see spoken so faithfully. It appears that education authorities, having been bidden from Whitehall to put medical inspection under the medical officer of health, have jumped to the conclusion that a cheap junior is good enough for the work, and that inspection is the sort of formal business that anyone can carry out, anthropometrical results being the chief aim and object of the system.

The System and its Future.

Now, as Dr. Kerr showed, the inspection should be devoted to the picking out of children with defects, ocular, mental, and so on, but that the school doctor should have a far more extended function than this, namely, that of studying the conditions of school work, of educational methods and routine, and of premises and apparatus. It is is obvious that, to give sound advice in these matters, a medical man, besides his technical knowledge, and besides some special knowledge of children, must be thoroughly *au fait* with the methods of education, and be in a very distinct degree a man of special qualifications. Such work has, indeed, no concern with the purely sanitary department, and requires a man of a type which can only be catered for by a public service. In our minds, the ideal should not be the subordination of the school doctor to the medical officer of health, but his amalgamation with the certifying factory surgeon, whose work in many respects is similar to his, as an independent public officer, free from the influences of local prejudice and independent of petty authorities. The Board of Education, however, have ruled otherwise, and, presumably, only bankruptcy of the present system can effect any change.

"Still They Come."

It is interesting, as a comment on the conditions of medical practice, to note that at the recent election of a medical officer of schools for Brighton no less than seventy-three candidates presented themselves. The salary of the post was only £300 a year, rising, at the discretion of the Education Committee, to £500, and presumably carried no extra emolument of any kind in the shape of pension, and so on. Yet for it there was an influx of applications such as one would have expected if the salary had been £1,000, rising to £1,500. The candidates, too, were of a high level of excellence, not mere disappointed "wasters" or adventurers. It seems, then, that the earning powers of brilliant members of the profession of the age of 30 or thereabouts may be put down at something below £300 a year, without anything much in the way of prospects. If any parents are thinking of putting their sons into the profession, they would do well to take note of the fact. Time was when an appointment of £300 a year was considered a pleasing addition to a practice; now it looks like being the be-all and end-all of medical existence. And the cry is, "Still they come."

It is a curious fact, noted from various parts of the United Kingdom, that an unusual amount of Eustachian deafness has been associated with the recent prevalence of influenza. Fortunately, the deafness is limited to weeks, or in some instances to two or even three months' duration.

LEADING ARTICLES.

THE RESEARCH DEFENCE SOCIETY.

The foundation of the Research Defence Society, under powerful auspices, marks a new stage in an old-standing social controversy. Hitherto the anti-vivisectionists have been permitted practically to work their own sweet will without let or hindrance. Now and then, it is true, there has been a public discussion, but it cannot be said that the whole case for comparative research has ever been authoritatively presented by those best qualified to speak. The only exception to that general statement was the expert evidence given in the action for libel in which the Hon. Stephen Coleridge was mulcted in heavy damages. The crushing blow inflicted by that lawsuit has been followed by a second Royal Commission, in which the anti-vivisectionists who have come forward have been subjected to a rigorous cross-examination as to the grounds of their statements. The wild rhetoric of the platform and the pamphlet is apt to cut a sorry figure beneath that kind of ordeal, and this was conspicuously the case in the present instance. In the most recently published report of the Royal Commission on Vivisection, an anti-vivisectionist, who had been engaged in practice as a qualified medical man for fifteen years, was taken over some of his statements in a book entitled "A View from Within." One passage described an experiment at University College upon a dog, which was kept alive by artificial respiration through a tracheotomy wound: "At each stroke of the bellows," he wrote, "a little ether was pumped in with the air—a much feebler blast than that used at Strasburg." It seems hardly credible that any person who had undergone any sort of scientific training could advance a definite statement of that kind, depending solely for his information upon his own unaided senses of sight and smell, and upon memory of what he had seen at Strasburg on a previous occasion. Yet such appears to be the inevitable deduction from the published evidence. Moreover, the witness further admitted he had not inquired from either of the professors present as to the amount of ether used. The same writer began by saying that his book was written to inform the public of what went on in the laboratories. He had worked for several months in various Continental laboratories, but never in an English one. In his book he wrote: "My knowledge of what is done on the Continent, and my studies of the *Journal of Physiology*, which details some of the experiments carried on in this country, prove to me absolutely that vivisection in Great Britain is not different in nature or scope to what it is on the Continent." In evidence he suggested that it was probable, judging from human nature, that the (English) vivisector did not always take care to see that the animal was properly anæsthetised, believing as he did that the animal felt little pain. Yet this witness was compelled to admit he had not a single fact to lay before the Commission in support of that belief, although, at the same time, he adhered to his opinion that the existing Act had had no influence whatever upon the practice of vivisection. We have adverted to the Commission because it affords a striking instance of the general value of the average anti-vivisectionist's intellectual methods. Before the test of logical examination his so-called facts, his propositions, and his conclusions are, as a rule, found to be grotesque and worthless. It is to be hoped that the work begun by the two Commissions that have sat on the subject will henceforth be continued by a Society which includes amongst its members many of the most distinguished names in the social and scientific life of the United Kingdom. The number of eminent medical men is overwhelming, a fact that is of immense significance when contrasted with the scanty handful of medical practitioners who can be claimed by the anti-vivisectionist party, and of those we do not recall the name of any sngle one of established scientific standing. The President of the Society is Lord Cromer, and its Secretary, Mr. Stephen Paget, who has for many years played the part of a virile protagonist in the championship of reason and of knowledge against the attacks of blind sentimentalism and prejudice. The keynote of the new body may be gathered from the opening sentence of its recently-issued circular, which runs :—" A Society has been formed, with the name of the Research Defence Society, to make known the facts as to experiments on animals in this country; the immense importance to the welfare of mankind of such experiments; and the great saving of human life and health directly attributable to them." The letter will be found printed in full elsewhere in our present issue. We cannot doubt that the Society will be joined by a large additional number of medical men.

AMERICAN MEDICAL LITERATURE.

We are all accustomed to the new spelling which characterises many, and, indeed, the majority of American works on medicine, and we have perforce to accept it with all its nerve-grating effect. We are not, however, as yet so accustomed to the absolute disregard of all the elementary principles of grammar which also is beginning to characterise these works. We have before us the last edition of our very excellent contemporary, *Surgery, Gynæcology, and Obstetrics*, a journal which always contains something new and interesting. To an English reader, however, the value of many of its articles is greatly impaired by the fault to which we have alluded. Isolated mistakes or solecisms in grammar may be made, and often are made, by the most experienced and careful of writers, but the continuous flow of illiteracy which characterises many American articles can only be the result of an entire contempt for what we may call, for want of a better name, the amenities of literature. This contempt is already manifest in the case of American orthography and etymology, and it is now coming to a climax in the case of grammar. Should it continue to make its present rapid progress, there can be little doubt that in a short time the American language, as spoken and written in one State, will become unintelligible, not alone to the British, but even to the inhabitants of the neighbouring States. Here are a few extracts from the journal to which we have alluded. In an article on "Breech Presentation" we are informed that "breeches in primiparæ are common"; that "breech presentations in contracted pelvis should have an early Cæsarean section"; and that "the material for this paper is 250 cases of breech deliveries." In an article on the "Supports of the Uterus," we are told that "the abdominal contents in an elastic sac are composed of liquid, gaseous, semi-liquid, semi-solid, and solid material of variable quantities." In an article on the "Abdominal Incision" we read that "this" (a particular form of incision) "gives a very firm closure, but does not give the access to the pathology that Pfannenstiel's incision does for the lower pelvis." In an editorial article we read that "the patient will require the constant attendance of an accoucheur, and the liquid will require to be let out at first indication of undesirable action." With so much contempt for literary amenities on the part of the respective authors, it is not strange that the printers should be similarly affected. Thus we find that the word "knowledge" is divided thus—knowl-edge; "alkaline" is spelt "alculine"; the expression "seven months' gestation" is printed without an apostrophe. Still, on the whole, the American printer, like the American artist, is vastly superior in *technique* to the American author. We do not bring forward these criticisms in any unfriendly or carping spirit, but simply because we want to emphasise the general disorder which is bound to creep into any subject once we begin to disregard rule. In America the President tries to alter the established orthography in the case of Government documents at Washington, and, as a result, Dr. Double Dash, in Nebraska, considers that he can pitchfork his words into sentences, irrespective of any guiding rules, so long as the sharp American intellect can deduce a meaning from them. There must be men in America who dislike and condemn this growing form of neglect, and if they would save the literature of their country from dropping apart into as many dialects as there are States, or even districts, they must speak at once.

CURRENT TOPICS.

Mr. Coroner Troutbeck on Anæsthetics.

In the near future it seems more than likely that a good deal of attention will be given to the subject of deaths under anaesthetics. Some recent remarks on this point by Mr. Troutbeck, the Coroner for Westminster, are worthy of careful consideration. He said that everyone who read the voluminous criticisms that were going on in the Press, both medical and lay, would see that there was an immense variety of opinion on the subject of anæsthetics. The function of coroners and juries was not to determine what was the best course for a doctor or an anæsthetist to pursue. That was the business of those gentlemen, and what coroners and juries had to satisfy themselves on was whether the cases were approached by persons who possessed the requisite skill, and whether death occurred in spite of their skill. It was obvious that they had to rely mainly on the evidence of persons whose conduct they were inquiring into, and the only possible check they could have was that a post-mortem examination should be made by some one who was not connected with any particular hospital and the medical men there. True, it was not a great check, because the important evidence came from those who were connected with the life of the patient and who were present at his death. Still, it was a check. There is a good, solid substratum of common sense in Mr. Troutbeck's remarks. Were it not that he invariably displays a profound distrust of the competency of the general practitioner to perform post-mortem examinations and to give evidence at inquests, we should endorse his views readily enough. As it is, most medical men will suspect him of special pleading on behalf of his "expert" henchman, Dr. Freyberger.

Proposed Memorial to the Late Professor Annandale.

IT is well that lasting memorials should be founded in memory of those of our brethren who have attained professional distinction in the battle of life. In the field of medicine the crown of honour is bestowed only upon those who have shown both strength and courage through many years of arduous toil. It has been proposed to establish such a memorial in the case of the late Professor Annandale, the well-known Professor of Clinical Surgery in the University of Edinburgh. Many friends and former pupils in all parts of the world will be glad of an opportunity of testifying their regard to their former teacher. The proposal is, briefly, that a fund should be raised for the purpose of awarding a gold medal annually to the best student in clinical surgery at the final examination, to be known as "The Annandale Gold Medal in Clinical Surgery." In addition to this, it is thought that a bust of the late Professor should be placed in the lecture theatre of the Royal Infirmary, Edinburgh, so long associated with his teaching. As the late Professor Annandale identified himself so closely and for so many years with the athletic life of the University, it has been suggested that, if there should be any surplus after providing for these objects, it might be devoted to some memorial in connection with the athletic club. The Committee have appointed Mr. H. M. D. Watson, C.A., 13, Rutland Square, Edinburgh, as Secretary and Treasurer.

Nursing Home Expenses.

THE desire to grow rich rapidly has presumably overtaken the average proprietor of the nursing home. At any rate, the fees charged in many of these institutions are on a scale that may fairly be characterised as extortionate, while a few deserve a stronger epithet. In forming any estimate of what is a fair remuneration for that kind of accommodation, there are, of course, a number of things to be taken into consideration. A properly equipped nursing home cannot be carried on without a large and competent staff, and a good many expenses in various directions, to say nothing of the initial outlay upon furniture and fittings. Nor will any reasonable person grumble at a fair charge, which would not drive persons of moderate means into the voluntary hospitals, where they occupy beds that were meant for the use of the poor. The excessive charge of the nursing homes and the large fees of the surgeons are leading to complaints from the public on all hands. To meet the difficulty it has been suggested that paying hospitals should be established on the basis adopted in almost every large town in the United States and Canada. There any degree of accommodation can be secured, varying from a luxurious suite of rooms for the millionaire to the single room or even the cubicle for those of moderate means. Some such adaptation of nursing home charges to the purse of the patients is absolutely necessary if justice is to be done to the poor, to the hospitals, to the sick public, and to the medical profession.

Schools for Defective Children.

IT would be hard to find a more conspicuous instance of the humane tendencies of modern times than the way in which defective children are cared for by the State. Last week the Chairman of the London Education Committee opened a special school for that class of children in the poorest part of Whitechapel. In declaring the school open, the Chairman said that that was the twenty-eighth school for physically defective and the eighty-seventh for mentally defective children. Though the ground was by no means covered, yet they were making good progress. More would be done in future to develop the trade side of the instruction. Dressmaking classes were to be started for the girls, and various trade classes for the boys; and the Committee was doing its best to find out the best things to teach the children. Under a proper scheme of education it may be hoped that many physically defective children may be rendered productive and self-supporting members of society. In such an event the money of the ratepayers will be well spent, although it will be hard to convince some of them of the justification of conveying the children to and fro daily in horsed vehicles and ambulances.

Health Reform in Ireland.

FEW philanthropic societies have such a successful record of work performed in the first year of their existence as the Women's National Health Association of Ireland, of which Her Excellency the Countess of Aberdeen is the active President. The first annual report presented at the meeting of the General Council last week in Dublin gave evidence not only of an enormous amount of energetic educational work performed and in progress, but of considerable solid results of that work. The Tuberculous Exhibition which was held in Dublin in October last has since visited, or arrangements have been made that it should visit, some fifty other towns in the country. The interest taken in the exhibition, and in the lectures delivered in connection with it, has shown itself in action by an increase in the number of open windows, by a decrease in the habit of spitting, by increased care as to the purity of the milk supply, and by increased activity on the part of public bodies in the direction of providing hospital treatment for consumptive patients. The activities of the Association, however, are not confined to the campaign against tuberculosis, for it has also taken up seriously the subject of infant mortality, with which it hopes to deal more effectively during the present year. We trust that in this direction, as in the other, its efforts may be fraught with success.

Country Practitioners and Vaccination Fees.

THE value of local organisation on the part of medical men has been repeatedly demonstrated of late in various parts of the kingdom, notably, amongst others, at Coventry and Sheffield. The rural medical officers of the Scarborough Poor-law Union are following suit, and have practically gone "on strike." The reason of their discontent is the recent decision of the guardians reducing vaccination fees to the absolute minimum stipulated in the Local Government Board order on the subject. A return to the old scale is demanded by the rural vaccination officers. Their contention appears to be reasonable, inasmuch as they are often called upon to travel long distances. One of them, for instance, mentioned that he had to pay visits at distances of six and seven miles, and part of his district included the hilliest part of Yorkshire. Under these circumstances it is easy to see why they should decline fees which might be considered adequate in the case of urban vaccination officers in the town. The matter is under the consideration of the Scarborough Guardians, and it is to be hoped that the firm attitude taken by the local country practitioners will be crowned with success.

Administration of Midwives Act.

The report of the Gloucester County Council Medical Officer of Health as to the administration of the Midwives Act in 1907 has been presented to the local authority. The total number of certified midwives on the Register was 361; some 18 to 20 are still required for districts at present unprovided. There is no certified midwife in nine out of a total of fourteen workhouses. The number of notices requiring medical help was 400, as against 399 and 256 in 1906 and 1905 respectively. A good deal of practical supervision and instruction appears to have been given. The report is of much interest, inasmuch as it drew marked attention to the dearth of certified women and the difficulty of obtaining their services in country districts. The fact appears to be now getting more generally recognised that under the most favourable conditions as to age and regular employment, the living to be made from the occupation in question is meagre in the extreme. Indeed, it is in many cases impossible to make a bare subsistence wage even when the midwife is clever and capable enough to eke out her income from work of other kinds. Sir John Dorington, speaking at the Gloucester Council, said that, although the Act was, perhaps, necessary in towns, it was inapplicable in the case of villages and hamlets, and he feared a very great disaster, a very sad and lamentable state of things, would be brought about by the inability of the local authorities to make the required provision. This severe criticism appears to be based on somewhat substantial grounds.

The Notification of Measles.

The high death-rate from measles has long been the despair of sanitarians. Although a mild disease, under proper conditions of care and treatment, it becomes a veritable scourge in the houses of the poor, who assume that, being a mild disease, it wants neither nursing nor medical attention. The ætiology of the malady is still so uncertain that it is difficult to conjecture in what direction the ultimate control of measles will be, for some day or other scientific medicine will undoubtedly attain a mastery over that as of all other zymotic diseases. Possibly the identification of the specific pathogenic micro-organism will be followed by the successful introduction of a curative vaccine or serum. Meanwhile, the early infectiveness of the disorder has baffled all the attempts of sanitary authorities to check the ravages of one of the most disastrous of all the exanthemata. Notification has not proved of much good, possibly because it has been applied only within restricted areas. In the case of hydrophobia muzzling was of little use until it was made universal throughout the kingdom. Meanwhile, those local authorities that have had the courage to apply the principle of notification deserve the thanks of the community. Some twenty years ago Coatbridge tried the experiment for seven years, but the Council found results not commensurate with the cost. However, it has been decided to extend for two years a recent brief period of compulsory notification of measles in the district. This public spirited action will be watched with interest in many quarters.

PERSONAL.

The King of Denmark and the Royal Family were present at the inauguration of a clinic for internal diseases opened in connection with the Finsen Medical Light Institute.

The salary of Dr. Michael J. Nolan, Medical Superintendent of the Down District Asylum, Downpatrick, has been raised from £700 to £900 a year.

A dangerous attack was made on Dr. Civel, of Brest, while seeing patients at the hospital in that town; one of them suddenly fired at him with a revolver. Fortunately, the bullet missed its aim, but struck another patient in the room.

Two well-known foreign medical men passed away last week in the persons of Dr. von Schrötter, Professor of Medicine in the University of Vienna, the distinguished laryngologist, and Dr. F. Terrier, Professor of Clinical Surgery in the Paris Faculty of Medicine.

A memorial is on foot to perpetuate the memory of Prof. Annandale, by the establishment of a gold medal in Clinical Surgery and a bust to be placed in the Royal Infirmary, Edinburgh. The Memorial Committee includes Sir William Turner and Mr. I. M. Cutterill.

The seventy-sixth annual meeting of the British Medical Association is to be held at Sheffield in July, 1908. Mr. Simeon Snell, F.R.C.S.Edin., ophthalmic surgeon, Royal Infirmary, Sheffield, is the president-elect, and the hon. local secretary is Mr. Sinclair White, M.Ch., F.R.C.S., Ranmoor, Sheffield.

Mr. J. J. Walker, M.R.C.S., of Peterborough, and Professor H. P. Keatinge, Director of the Government Medical School at Cairo, have been elected Fellows of the Royal College of Surgeons of England without eamination, in recognition of their distinction in surgery.

A handsome presentation was made at the Sutton Coldfield Medical Dispensary on April 15th to Dr. A. H. Evans, on the occasion of his retiring from his duties in connection with this institution. It took the form of a handsomely chased and inscribed silver cake-dish, and was handed to him by the President, Mr. E. J. Brookes, on behalf of over a hundred of the doctor's dispensary patients.

A tragic accident has marked the opening of the climbing season in Cumberland. The victim was a medical student, Mr. David Howard Caine, son of the late Mr. W. S. Caine, M.P. He was paying a visit to Wastdale Head, having done a little unpretentious climbing last year. He arrived at Wastwater Hotel, and left the next morning about 11 o'clock ostensibly for a walk. He appears to have been last seen going up towards Burnthwaite on April 13th, and nothing further was heard of him until his body was found on Wednesday afternoon.

A Clinical Lecture

ON

THE MEDICAL TREATMENT OF PHLEBITIS.

By PROFESSOR ALBERT ROBIN, M.D.,

Of the Paris Academy of Medicine.

[Specially Reported for this Journal.]

Even in affections the ætiology and pathogenesis of which are well known to us, ætiological and pathogenetic therapeusis runs often only along parallel lines, the morbid state which we wish to modify running its own course independently of the determining cause. Still we must always direct our attention to the ætiological factors when accessible, because their persistence tends to aggravate the morbid state resulting therefrom. Such is the case in phlebitis.

The infective origin of phlebitis is generally admitted, whether medical, puerperal, or surgical. Even *phlegmasia alba dolens* must be included, thus bringing it into a general category, the constituent elements of which are distinguished from each other by the mode of infection, the nature of the infection, the severity, the extent and the soil which are of capital importance from a nosological point of view, but, save in respect of the soil, hardly bear upon treatment which must be directed simultaneously to the causal infection and to the venous lesions to which it has given rise.

These remarks are applicable to the two patients under treatment in our wards, who are both entering on convalescence.

The first patient is a dressmaker, æt. 39, who has gone through two pregnancies to term without any complication. At the beginning of January, consequent upon overwork and possibly also on sexual excesses, she complained of a dull pain in the hypogastrium, rendering walking and standing difficult, accompanied by a copious, thick leucorrhœal discharge. In June she had copious metrorrhagia, for which she was admitted to Lariboisière, which she left a month later. In August, however, she was obliged to return to hospital in consequence of further hæmorrhage, this time into a surgical ward. She declined surgical treatment and went home, where she lingered on until November 15th, when she came to us.

She was diagnosed to be suffering from chronic parenchymatous metritis with slight ulceration of the cervix, copious leucorrhœa and readily-provoked bleeding. She was put on a treatment which I shall describe to you on a future occasion, but on December 15th she complained of lancinating pain and dull aching in the left lower limb, which became somewhat swollen, while the temperature ran up to 102·3° by January 1st. On this date she experienced acute pain in the calf and groin, and the entire limb became the seat of white, hard œdema.

The other patient is a married woman, æt. 22, who passed through a normal confinement on December 18th. She got up on December 30th to attend to her household duties, but on January 4th she noticed that she was passing very little urine, and that evening she was seized with acute lancinating pain in the left calf, this having been preceded by a sort of general numbness of the limb. The limb swelled up on the following day, and in 24 hours the œdema reached the hip. She was admitted on January 6th with a temperature of 103° F.

Both these patients were suffering from phlebitis of the left internal saphenous vein. A hard, tender venous cord could also be felt in the calf, and there was some effusion into the knee-joint. In view of the course in both cases it is highly probable that the phlebitis began in the calf veins, spreading thence to the internal saphenous.

From the point of view of treatment we recognise three stages in the evolution of an attack of phlebitis:—(1) An acute stage which corresponds to infection of the endovein, the formation of a clot and defensive retraction of the vein wall. (2) A period of convalescence or resolution, during which the venous lesions undergo sundry regressions, the clot becomes permeated with connective tissue and vascular granulations that absorb it in part and set up solid adhesions with the remainder. (3) A so-called residual stage at which all active retrogression is at an end and which is characterised by the existence of more or less obliterating lesions, and venous and trophic disturbances consequent thereupon.

During the first stage treatment is purely passive, and is limited to keeping the limb at rest, and measures directed to the causal infection. In the second stage treatment must be directed to bringing about absorption of the clot and repair of the venous wall lesions, with which object various physical and medicinal agents are brought to bear. In the third stage treatment must be active, since in its absence the residues may become permanent or will take a very long time to disappear, even in part.

Now, our two patients have been under observation quite from the onset, and as the infective origin of the lesions was undoubted we began by immobilising the damaged limb, at the same time treating the source of the infection as well as the infection itself.

Directly we are confronted by phlebitis, whether accompanied or not by fever, our first duty is to completely immobilise the affected limb. We made use of a metal gutter-splint, extending right up the thigh and fixed by a bandage. Before placing the limb in the splint it is covered with a thick layer of wadding, wide enough for the ends to be folded over each other in front, whereupon the apparatus is fixed by tightening the straps. I prefer straps to a bandage because it is easier to get at the limb to see how it is getting on. Before applying the wadding to the limb it should be dusted with a mixture of powdered talc and boracic acid.

Inasmuch as the patient cannot be expected to remain perfectly still, the limb should be placed in a sling or suspended in some way. Movement of the limb will thus be reduced to a minimum.

I see no advantage in the application of medicinal substances at this stage. Their application involves a certain unavoidable amount of movement and pressure which are not devoid of risk, and more than compensate for any advantage that might attend their use. If, however, there be much pain we may apply to the painful area a compress steeped in:—

Tinct. belladonnæ,
Extract opii. liq.,
Extract hyoscyami, āā 1 oz.

For the purpose of checking further infection, in the first case we ordered copious vaginal injections of boiled water at a temperature of 110° F., with tannin and laudanum, together with compresses to the abdomen steeped in the above lotion. I use tannin because I wished not only to sterilise the vagino-uterine secretions, but also to exert a curative influence on the ulceration of the cervix.

In the other patient, who still presented a fœtid lochial discharge, I ordered a slow intra-uterine injection of boiled water at 104° F. with chloride of zinc, followed by tannin injections twice daily, as in the former case.

When we wish to combat an infective condition nothing is better than hypodermic injections of metallic ferments (silver, platinum or palladium), to be made a couple of inches from the venous trunk that is involved. The effect in both these cases was remarkable, for the very next day, after subsidence of the slight rise of temperature which almost always follows these injections during the first few hours, the fever fell, permanently in the first case, but returning in 48 hours in the second, only to disappear for good after another injection.

There is no necessity to give antipyretics in presence of fever, since the injection of metallic ferments does all that is required. This may be repeated every other day in 10 cc. doses as long as there is any temperature. The best preparations to employ are the solutions that are neither stabilised nor isotoned, containing about three-hundredths of a milligramme (about 1/1700 of a grain) of the metal in each cubic centimetre. As far as my knowledge goes, no importance attaches to the choice of a particular metal.

The patients should be kept on milk diet or lacto-vegetarian diet so long as there is any temperature. When this has returned to normal they may be put on a mixed diet in accordance with their appetite and digestive powers, taking care to keep the bowels regular. The latter may be secured by means of enemata of tepid boiled water, or by giving after meals a warm infusion of senna leaves.

Immobility must be maintained on an average thirty days after the last rise of temperature. When, however, there has been no rise of temperature it may be reduced to twenty-five days or three weeks, never less. In any case, it is better to err on the right side for prolonged immobility entails no drawbacks at all comparable with the danger attending premature movement.

The surgical treatment of phlebitis has been recommended on the ground that it averts all danger of embolism, avoids the necessity for prolonged immobility, and is a safeguard against recurrence; but, in my opinion, surgical intervention entails far greater risk than the medical treatment, save in a few exceptional cases of varicose phlebitis with marked tendency to embolism and recurrence.

At the present time thirty days have elapsed since the last rise of temperature in our first patient, the second being in her twenty-fourth day. We have to decide on our attitude during the second stage which has now arrived, the stage of resolution and convalescence. When we have decided that immobility may be dispensed with we loosen the straps or bandages, open out the splint, leaving the limb therein for from twenty-four to forty-eight hours. On the third day we take off the splint and gently cleanse the limb, which is then wrapped in cotton wool, fixed by four strips of bandage. Matters are left thus for four days, unless there should be a rise of temperature or pain, in which event this stage is prolonged until things have returned to normal. After the four days take off the cotton wool and leave the limb free in bed. We may then proceed to a more thorough cleansing of the skin.

Now is the time for us to employ medicinal and physical agents. The most generally employed of the medicinal agents is hamamelis virginica, on account of its vaso-constrictive properties. Every morning the limb is gently rubbed with the following ointment:—

Ext. hamamelis liq., 3 parts
Benzoinated lard, 30 parts.

This drug should also be given internally in conjunction with viburnum prunifolium, which has the same properties. These are usually given in from 30 to 60-drop doses daily, but the effect is almost always to upset the stomach, so I prefer to give 10 drops daily of the following mixture:—

Ext. hamamelis liq.
Ext. viburni prunifol, āā 10 parts.

We get better effects from a small dose that is well borne and can be continued for a long time than from large doses that will soon have to be suspended on account of digestive disturbance.

Now comes the highly important question of movement and massage of the limb. We have recognised the error of the old teaching, according to which forty days' immobility was a minimum, since we learned from Cornil and Marie that after the sixth day of an attack of phlebitis there is already a sufficient reaction on the part of the venous wall to determine the formation of neo-capillaries that penetrate the clot, develop connective tissue, and soon convert clot and vein-wall into a cicatricial cord. We must not, however, go as far as Marchais, who asserts that this process is so rapid that phlebitis has ceased to be dangerous by the time the diagnosis is clear, and who attributes delayed embolism to subsequent inflammatory outbreaks in another part of the vein. Nor must we fall into the exaggeration of Delore and Poullet, who forbid active measures until several months have elapsed after convalescence. As a matter of fact, we may commence passive movements about six days after removal of the splint, taking the temperature regularly, and desisting should there be any rise.

Begin with movements of flexion, circumabduction and extension, first of the toes, then of the foot, without lifting the foot from the bed. A few days later we may tackle the knee, and, finally, practice abduction and adduction of the limb, which may also be slightly raised.

If these movements provoke no reaction, in ten days or so we may start on the veins, first by allowing the limb to hang out of bed for a few minutes at a time until it begins to get livid. Later on, the patient will be allowed to put the foot to the ground after stretching it on a plank which answers the purpose of an inclined plane.

At this stage I strongly forbid movements intended to combat the muscular atrophy by stimulating contraction, moving the joints, and, more particularly, manipulation of the veins themselves. If, however, by massage you merely mean manipulations that tend to stimulate innervation, circulation and nutrition without entailing any risk of displacing the clot or setting up some latent inflammatory process, then I am with you.

Therefore, only have recourse to the gentlest possible *effleurage* without any pressure and still without touching the phlebitic veins. Practised thus the *effleurage* may stimulate the skin and through it the peripheral circulation without inducing any change in the anatomical condition of the veins. In any case, this treatment, repeated daily for ten minutes or so, tends to get rid of the œdema and curtails the duration of convalescence.

To assist the action of the superficial *effleurage* the limb may be rubbed every evening with the following ointment:—

Ext. ergotæ liq., 3 parts.
Potassii iodid.,
Ext. nucis vom., āā 2 parts.
Vaseline, 30 parts.

The extract of ergot exerts a tonic action on the superficial veins, the iodide is a mild, but trustworthy resolvent, and the nux vomica stimulates cutaneous innervation.

I also recommend applying a mixture of two parts of iodine liniment and one of laudanum over the veins with a brush.

The duration of this period of convalescence, during which the patient remains in bed, varies from fifteen to thirty days. It may be regarded as at an end when pressure on the veins elicits no tenderness and all œdema has disappeared.

We now enter on the residual stage. The initial process has subsided, but the circulation in the limb is more or less defective, and it soon becomes cyanosed when allowed to hang down. All the muscles are wasted and their place is taken by fat, œdema is readily provoked, and the skin is thickened. There is a variable amount of functional impotence; lastly, the patient often complains of shooting pains in the limb, these pains being usually neuritic or neuralgic, to be distinguished from the early venous pain by the fact that pressure on the veins is no longer painful. This distinction is not without its importance, because should the pain be venous we must hold our hands or even retrace our steps awhile, whereas if merely nervous or neuritic it should disappear under treatment.

The treatment consists principally in baths and packs, *effleurage* and real massage, movements and medicinal agents.

A daily bran bath, at a suitable temperature, in which is dissolved a packet of salts resembling those of Bagnoles de l'Orne water, viz.:—

Sulphur monosulphide, 2 gr.
Sodii chlor., 4 dr.
Calcii biphosphat., 1 dr.
Calcii sulphat., 8 gr.
Ferri et manganese chlor., 2 gr.
Calcii bicarbonat., 25 gr.
Magnesia bicarbonat., 40 gr.
Lithine silicat., 10 gr.
Potassi silicat.,
Aluminis silicat., āā 40 gr.
Sodii arseniat., 2 gr.
Gelatin, 2½ dr.

For one packet

The active principles in this powder are the arseniate of soda and the silicates, which are intentionally prescribed in comparatively large doses.

The duration of the baths at first will be fifteen or twenty minutes, gradually increased to forty minutes. The patient is left in bed for an hour after each bath, after which ten minutes' *effleurage*, as described above. Then another ten minutes' rest, whereupon the patient may get up and take a few steps, to stop at once should the limb tend to become cyanosed or should there be any pain or aching in the limb.

Order twenty or thirty of these baths, then desist for a fortnight or so, then three times a week.

The *effleurage* must be as gentle as possible to begin with, then gradually strengthened, but still avoiding the damaged veins. After a time we may employ genuine massage, but under no circumstances must we manipulate or rub the region of large veins, *i.e.*, between the poplitei, in the popliteal space, Hunter's canal and Scarpa's triangle.

Active movements will be necessary to stimulate the nutrition of the atrophied muscles and to get rid of cutaneous thickening and superfluous fat. We must begin with flexion and circumduction of the thigh, aided by walking in short steps, stopping on the supervention of fatigue or heaviness.

The patient must not be allowed to remain erect, when standing he must walk in order to avoid venous stasis and to assist the return of the blood by muscular contraction. Advise them never to sit with crossed legs, these to be always extended in the horizontal position.

At this residual stage local moist applications are of great service. We may employ compresses steeped in lead lotion or in a solution of sal ammoniac (5 to 10 per cent.).

Medicinal agents, though less active, must not be neglected. Iodide of potassium and arseniate of soda are useful adjuvants. Order a tablespoonful of the following mixture to be taken just before lunch and dinner:—

Sodii arseniat., 1¾ gr.
Potassi iodid., 80 gr.
Aquæ destil. fl., 10 oz.

F.M.

To be taken for ten days, then discontinued for a like period, and so on until complete recovery.

I am not in favour of making the patient wear an elastic stocking at this period, for I prefer to leave muscular action unhampered, inasmuch as this favours the re-establishment of the collateral circulation. Merely apply a crêpe bandage lightly round the limb, and not until the patient resumes his ordinary occupation will you authorise his wearing an elastic stocking.

Recovery will be completed and confirmed by one or two courses of treatment at a thermal station. Bagnoles de l'Orne has acquired a special reputation in this connection, but it is by no means the only one. The thermal treatment accelerates the venous circulation, diminishes hæmostasis and disperses all traces of œdema. In arthritic subjects the internal administration of the water will be attended by benefit. Among other stations may be recommended Ussat, Brides-les-Bains, Aix-les-Bains, Plombières-les-Bains, and Bourbonne-les-Bains.

In presence of undue adiposis, muscular atrophy and hard œdema, the mud baths of St. Amand and Dax can be recommended.

I may appear to have dwelt unduly on details, but you will find in practice that none of these is unimportant, and the best results can only be obtained by careful attention to the minutest precautions.

NOTE.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by David Newman, M.D., F.F.P.S.G. Surgeon, Royal Infirmary, Glasgow. Subject: "The Value of Early Diagnosis in Surgical Diseases of the Kidney, with Special Reference to Physical Methods of Examination."***

ORIGINAL PAPERS.

ON ASCITES RELIEVED OR CURED BY PARACENTESIS. (a)

BY FRANCIS HAWKINS, M.D., M.R.C.P.LOND.,
Physician to the Royal Berkshire Hospital, Reading.

(Concluded from page 454.)

CASE V.—Paracentesis performed eight times in two years; no re-accumulation for three years; death.—A man, æt. 25, single, had formerly been in the army, and when in India suffered from enteric fever and malaria, and was invalided home two years ago, his papers stating that he had heart disease. In July, 1895, he noticed that his feet were slightly swollen. This disappeared, and on his applying to enter the police force, it was found he had a varicocele. For this he was operated upon, and some time afterwards—about two weeks, he thinks—he noticed that his abdomen was gradually getting larger, and he experienced difficulty in buttoning his trousers. On July 14th, 1896, he was admitted under my care. He had never been a heavy drinker, and had not suffered from syphilis. He was a tall, well-built, well-developed man. There was no swelling of the feet; the abdomen was much enlarged, especially in the flanks (the umbilicus was not everted), and evidently contained free fluid. The liver dulness extended from the fifth rib in the nipple line for 7½ in.; its lower border could be distinctly felt as very firm and smooth. He had never suffered from hæmatemesis or melæna. He complained of palpitation on any excitement, and the apex beat was very distinctly seen in the fifth interspace inside the nipple line; no murmur was heard. The lungs were normal. In 24 hours he passed 30 oz. of urine, sp. gr. 1020; no albumin; temperature, 98.4°. On February 3rd he passed blood by the bowel. On February 26th a distinct systolic murmur was heard at the apex. The abdomen slowly but gradually increased in size, and on March 13th paracentesis was performed, 3 pints, 16 oz. of clear fluid being withdrawn. The abdomen was then tightly bound. On March 28th 18 pints were withdrawn, and on April 24th 16 pints 10 oz. The urine now increased in quantity, but no albumin was present. On May 22nd 17 pints 10 oz. were withdrawn. He afterwards complained of a feeling of soreness over the whole abdomen, and the temperature rose to 100°. A few days later he was allowed to sit up, and the fluid not re-accumulating to any amount, he was discharged on July 4th, but was re-admitted on October 3rd, and on October 20th 20 pints of fluid were drawn off. On this occasion he fainted, and the temperature rose to 101°. He, however, soon recovered, and was discharged nine days later. He was again admitted on January 23rd, 1897, and six days later 36 pints 10 oz. of fluid were removed. The urine had now sp. gr. 1002, no albumin. He was discharged on February 9th, and paracentesis was not required until July, when 34 pints 10 oz. were removed. He was now so much better in health that he joined his brother in the business of a greengrocer, and I frequently saw him about the streets; but in March, 1898, he again came to the hospital. His skin was now somewhat yellow in colour, and a distinct double murmur was heard at the apex. On March 12th paracentesis was performed, and 27 pints of fluid of a brownish colour were taken away. This was followed by severe acute pain over the epigastric region. On this occasion the urine contained albumin for the first time. He was discharged on April 5th, and resumed his occupation. In June, 1898, he was again admitted to the hospital. The abdomen was somewhat distended, but there was no evidence of fluid. The liver was enlarged, and could be distinctly felt for a good four inches below the costal margin. Its lower border was firm, rounded and regular. There was some slight œdema of the legs; urine, sp. gr. 1010; albumin a trace; the murmurs at the apex were still present. Twenty days later he was suddenly seized with pain in the left leg; he had a rigor, and the temperature rose to 104°. The following day, when I saw him, the left leg was of a red colour, and much swollen, the whole leg being tender to touch. In six days the temperature became normal, the leg was less swollen, and there was no tenderness. He gradually improved, and was discharged in August. In November he was again admitted. He now complained of great breathlessness, a constant hacking cough, and much pain over the præcordium. Well-marked friction was heard all over the cardiac area; no murmur was now heard at the apex. There was no evidence of fluid within the abdominal cavity; urine sp. gr. 1010—trace of albumin. He was treated for pericarditis. The friction ultimately disappeared, his cough and breathlessness left him, and he was discharged on December 9th. I saw this man from time to time, and on no occasion did I detect fluid within the abdominal cavity. He was continuing at his work. I should, however, mention that he was becoming exceedingly emaciated. On January 19th, 1902, he was carried into the hospital, and the following note was made:—"Patient admitted almost comatose; cyanosis marked; all superficial veins, trunk and limbs distended and knotty; great dyspnœa; abdomen distended; fluid present. The following day the man died. In this case paracentesis was performed eight times in two years; no re-accumulation of fluid for nearly three years. I must now briefly describe the autopsy. The abdominal cavity contained five pints of pea-soup-like fluid. The omentum was shrivelled up, the mesentery thickened and shortened, and the intestines were greatly distended. The liver was covered with a thick greyish-white coating, resembling, as the house physician described it, "a bladder of lard." It was adherent to the diaphragm. The spleen was enlarged, and its capsule much thickened, somewhat resembling that of the liver. The heart weighed 23½ oz. The pericardium was universally adherent. The right auricle was calcified, as was the whole of the right ventricular wall, with the exception of a small part near its apex. Part of the left auricle and ventricle was also calcified. There was very little muscular substance left. The right pleural cavity contained some fluid. The pleura was thickened, and the lung was adherent all over the diaphragm. The left lung was universally adherent, and the pleura was in parts cartilaginous. The following is a report from the Clinical Research Association:—"The pleura consists of dense laminated fibroid tissue which is almost devoid of nuclei. The liver is similarly covered with a fibroid capsule, and, on section, the subjacent tissues are penetrated with strands of dense fibrous tissue. The hepatic substance shows much nutmeg congestion."

(a) A paper read before the Windsor and District Medical Society.

Ending my paper at this point, I should merely have shown that paracentesis had been performed in cases of ascites from the very earliest time, and have given particulars of cases where it had been a means of cure or relief. But I wish to proceed somewhat further and consider the pathological conditions present in these cases in order that we may the better understand in what class of case we may justly expect relief or cure after paracentesis. My last case affords us an opportunity of so doing, and it exemplifies a class of case which had not received much notice from a clinical point of view until Curschmann, in 1884, and Hale White, in 1888, directed attention to them. The former spoke of this condition under the name of "zuckergussleber," or "icing-liver," and pointed out its close resemblance to hepatic cirrhosis, and the latter under the name of "perihepatitis," while Rolleston describes it as a "universal chronic perihepatitis." These names are, I venture to think, unfortunate, because they seem rather to imply that the condition of the liver is the actual disease, whereas it is but partially so, and occurs only in association with other conditions. Hence, to my mind, the name given by Nicholls, of Montreal—viz., "multiple progressive hyaloserositis," or "chronic inflammation of the serous membranes," is better as expressing general rather than special local pathological changes. It is important to recognise that this universal perihepatitis is only a part of the disease, being secondary to and associated with changes in other serous membranes. In my case, seeing the advanced stage of change in the heart, it is reasonable to suppose that the disease commenced in that organ, but the changes were, as you will remember, multiple, and this was so in all recorded cases of which I have read. This disease is slowly progressive. The chief physical signs of the serous membrane within the abdominal cavity being affected is ascites. The effusion of fluid recurs in most cases again and again after paracentesis, and yet the exciting cause of this effusion of fluid may become latent for some time. In my case, after repeated tappings, no re-accumulation occurred for nearly three years. The most remarkable case of this disease, illustrating, as it does, the re-accumulation of the ascitic fluid and the value of paracentesis, is recorded by Rumpf. A female, æt. 33, when she first consulted him in 1869, died in 1885. During this time—that is, sixteen years—paracentesis was performed 301 times. This patient, however, could attend to her household duties up to the last year of her life. Rolleston refers to an interesting case of a woman under the care of Dr. Ewart, who was married after the twentieth tapping and died after the sixtieth. Osler refers to this condition in a child on whom paracentesis was performed 121 times. The duration of life in this disease varies, according to Nicholls, from two to sixteen years, the average duration being six years. My case, you may remember, lived about seven years from the first onset of the ascites. Here we have evidence of certain pathological changes within the abdominal cavity associated with ascites when paracentesis affords great relief

But, we must ask ourselves, are such changes present in the other cases recorded? I think not. These cases are cured; there has been no return of the ascites for many years. I think that in Case III. we may have some local, not universal, perihepatitis, because, although the notes of the case make no mention of the fact, on auscultation over the liver during the early part of the illness, friction was distinctly heard. I regard this case (3) as one where the ascites was associated with peritonitis with chronic renal disease, and I may here remind you that Fagge points out that when in a case of renal dropsy the abdomen is filled with fluid to a degree disproportionate to that of the serous effusion in other parts, this is probably due to perihepatitis.

Now, as regards Cases II. and IV., the ascites was, I think, associated with peritonitis and chronic renal disease. It is perfectly true that in both of these cases there may be some perihepatitis, but, as far as I know, there is no evidence to support it, and I think that all three of these cases differ from the class of case illustrated by Case V. True, the difference may be only one of degree, and not of kind, for Hale White regards chronic nephritis as a causative factor in cases of "formative inflammation." All such cases are liable to be mistaken for cirrhosis of the liver, and such cases as II. and III. are, I think, not common; at least, the study, both clinically and pathologically, of cases of chronic renal disease shows that the presence of ascites unaccompanied by serous effusion in one or both pleural cavities is an exception. I would, however, say, given a case of ascites, where the effusion of fluid within the abdominal cavity is out of all proportion to that in any other part, and where, in addition, you have albumin in the urine, paracentesis should be performed early, and should be repeated as often as is necessary. But for the scantiness and incompleteness of the notes, I might refer to another case of ascites which I believe to be due to chronic peritonitis. Here paracentesis was performed 36 times in one year, after which the man remained fairly well for one year, and then he died. This man had a large umbilical hernia. He died some miles away from

Reading, and I did not know of his death for some months afterwards, when I heard that, before his death, he had fæcal vomiting, and that the cause of his death had been given as strangulated umbilical hernia and cirrhosis of the liver. This leads me back once more to Case IV., where the liver was, in my judgment, in a state of early cirrhosis, and a more recent examination of the patient confirms this view. And you may naturally ask, was not the ascites due to the condition of the liver? I think not; for in studying the natural history of hepatic cirrhosis, one learns albumin is not of frequent occurrence in such cases—in other words, the kidneys are not often diseased in hepatic cirrhosis—and, further, when ascites occurs, it is usually a terminal sign, and although paracentesis may be deemed necessary and performed, yet the patient dies within six to eight months after its first being performed; and this applies, in my experience, to patients in the wasted, toxæmic condition, and also to the fat, non-toxæmic stage. Did time allow I would give illustrative cases, but practically the same view has been expressed by Frerichs, Murchison and others. But, in 1892, Bristowe, in a paper read before the Medical Society of London, recorded some cases which he diagnosed as cirrhosis of the liver, where the ascites was cured by paracentesis, and Cheadle in the same year also recorded similar cases; but more recent writings would tend to show that when the ascites is cured by paracentesis, it is not due to the cirrhotic condition of the liver. Hale White, for instance, found, on consulting the records of Guy's Hospital for five years, that not one single case of uncomplicated cirrhosis of the liver long survived after paracentesis had been performed. He concludes that, "The supervention of ascites in uncomplicated cirrhosis of the liver means that the end is near, and that if a case of cirrhosis of the liver lives long enough to require a second paracentesis, it is in the highest degree probable that either the diagnosis is incorrect, or, at any rate, some other cause than cirrhosis exists to explain the ascites." But I have wandered from my cases. And now as to the bearing of the first case. The ascites in this case I judge to be associated with tubercular peritonitis. I am well aware that the evidence from necropsies of cases of tuberculosis of the peritoneum would almost negative such a conclusion, but clinical experience will, I venture to think, support it.

THE SURGICAL TREATMENT OF THE IMPERFECTLY DESCENDED TESTICLE. (a)

By EDRED M. CORNER, M.C., F.R.C.S.,

Surgeon, Out-patients, St. Thomas's Hospital, &c.

It is impossible to give hard-and-fast rules of treatment for cases of imperfectly descended testicle, because they vary so much in themselves, particularly in their imperfections of descent, and also in their concurrent deficiency, imperfect development. There are, therefore, two points of greater magnitude to bear in mind in treating these cases—the imperfect descent, and the imperfect development. To improve the imperfect descent by operation in reality does the patient very little good. Indeed, although much can be done by operation to cure the imperfect descent, unfortunately little can be done to improve the second factor, imperfect development. It is impossible for us to make a dwarf grow to a Sandow, or an imbecile become a Darwin. They have not the requisite capital. Similarly, we cannot make a testicle grow to full size and maturity if it is not so designed and capitalised. In consequence, operations which are merely aimed at curing the imperfect descent of an imperfectly descended testicle must fall into disrepute, because they do not improve the development of the gland, which is by far the more important factor. Thus, by neglecting the question of the future development of the gland, the results of operations of orchidopexy are unsatisfactory. But not only do the operations of orchidopexy not improve the development of the imperfectly descended testicle, but often they actually do harm, by causing venous congestion and inflammation in the gland. Tersely it may be stated, that orchidopexy is an operation which very often fails, both anatomically and physiologically. Anatomically, because the gland fixed in the scrotum seldom remains there; physiologically, because the testicle is largely converted by it into useless connective tissue instead of useful epithelium. Except in very carefully selected cases, it is commonly a murderous operation. But as it is the most popular operation for imperfect descent of the testicle, it is necessary, having condemned it heartily, to examine very carefully into the other lines of treatment left to us, which are three.

The first; to leave the case alone.—This line of treatment can be pursued safely until one or any of the following occur: (*a*) attacks of pain in the testicle; (*b*) attacks of inflammation in the testicle; (*c*) hardening of the testicle; (*d*) dilation of the inguinal canal, or the development of a hernia.

The second; orchidectomy or castration.—This is only justifiable when the spermatic cord is twisted, the testicle much sclerosed, or the patient twenty-three years of age or more.

The third; orchidocœlioplasty or the abdominal reposition.—This is the most useful operation from the patient's point of view, because it neglects the comparatively unimportant imperfect descent of the gland, and ministers to the all-important imperfect development of the gland. An imperfectly descended testicle can rarely if ever form spermatozoa—that is to say, become spermatogenetic. So that its whole value may be taken to lie in its internal secretion, which is fostered by the abdominal reposition of the gland, and not in its external secretion. The reposition can be done in two ways, an extra-peritoneal orchidocœlioplasty, and an intraperitoneal orchidocœlioplasty. The latter is preferable, the gland being placed under conditions similar to those of the ovary. Increased liability of the onset of malignant disease is not incurred after orchidocœlioplasty, because it is not the abdominal position of the organ, but the concurrent imperfect development, which gives it its additional proclivity to become malignant.

From what has been said, particularly the four factors which should terminate the period of treatment by waiting—namely, pain, inflammation, hardening, and dilation of the inguinal canal, it will be seen that very few cases of imperfectly descended testicle will escape operation, especially when it is remembered that quite 80 per cent. are associated with a hernia sac. And having explained my ideas on the scope and limitations of the various lines of treatment, it only remains to state the cases in which the operation of orchidopexy is useful. It is particularly indicated in cases of movable testicle, slight imperfections of descent, and in the younger subjects, say under seven years of age.

(a) Read before the Harveian Society, April 9th, 1908.

DYSPAREUNIA IN THE MALE

OCCASIONED BY A CONDITION IN THE FEMALE.

By S. JERVOIS AARONS, M.D.Edin., M.R.C.P.Lond.,

Pathologist, Hospital for Women, Soho Square.

It is not often that the advice of a gynæcologist is sought by the male for dyspareunia, but on two occasions it has fallen to my lot to be consulted for such a condition.

In the first case, Mr. B. came to me, complaining that since the birth of their last child, intercourse had become painful for him, though having no such effect upon his wife. He said he was quite sure something must be wrong with her and only subsequent to the birth of the last child, coitus having been perfectly natural up to this point. He described the pain from which he suffered as of a cutting nature, which, at one time, was severe enough to prevent the act, and on the last occasion that coitus was attempted, he bled quite freely. I saw his wife, and on inquiry, found that her last labour had been normal, except that the perinæum had been torn (this had also happened at the two first confinements, but was promptly repaired by suturing.

On examination, the vagina admitted two fingers easily, no obstruction could be felt; in fact, everything seemed to be perfectly normal, visual examination at first gave no indication of the cause of the trouble, the perinæum *looked* all right. The lady then volunteered the statement that her husband complained that he felt as if he were entering a blind pouch low down; it was then that I examined the perinæum more thoroughly, and found that, although the superficial parts were healed, the deeper structures had not united. What happened was that the skin of the perinæum, when the penis was introduced, stretched like a thin band, with a tense cord-like edge; this was easily demonstrated with a glass dilator; it was this sharp edge of skin which was the cause of so much pain to the husband. I split this band centrally, and did a perineorrhaphy. The result has been perfectly satisfactory in every way.

The second case was of a totally different nature. Mr. T. sought my advice because intercourse was painful to both him and his wife; he felt sure there must be something wrong with her, as during coitus he seemed always to come into contact with a hard bony substance, which was so painful to him that he had frequently to desist from intercourse, and the knowledge that it was always going to be painful prevented them from indulging, except at very long intervals. They were very desirous of having a family, and although they had been married seven years there had been no sign of pregnancy.

I saw the wife, an intensely nervous woman, and examined her with considerable difficulty; she was quite virginal, penetration having never been effected. At the very commencement of my examination I soon found the bony substance complained of by the husband; this was the os pubis; directly I attempted to examine the patient, she, by arching her back, completely altered the normal position of the introitus, so that the examining finger impinged upon the os pubis; this is what always happened to her husband whenever he approached her, and was caused by fear of pain. The hymen was exceedingly tough and inelastic, and would only admit the little finger; locally, nothing else of an abnormal nature could be detected. Sexual desire and feeling were non-existent in the female, but she ardently desired a family.

I resected the hymen, dilated the introitus, and made the patient wear a glass vaginal plug for a few hours every day for a week. The result was eminently satisfactory, coitus was easily and naturally performed, and sexual feeling was soon established. Within three months of the date of the operation the patient became pregnant.

The Honyman Gillespie trustees have appointed D. E. Anderson, Esq., M.D.Paris, M.B., B.A., B.Sc., London, F.R.S.E., etc, to the Honyman Gillespie Scholarship and Lectureship in Allopathic Medicine.

HENOCH'S PURPURA,

AND ITS ASSOCIATION WITH INTUSSUSCEPTION. (*a*)

By HUGH LETT, M.B., Ch.B., Vict., F.R.C.S.,

Assistant Surgeon to the London Hospital and the Belgrave Hospital for Children.

This paper is founded on a case of Henoch's purpura in which an intussusception developed. Briefly, the clinical features of the case were as follows:—The patient, a child, æt. 3, had always been perfectly well until September 27th. On that day he had frequent stools which were partly formed, and in the evening the left knee and elbow were painful and swollen. The next morning both legs were swollen and he had severe paroxysms of abdominal pain. In the afternoon two purpuric spots were noticed on the left leg. The following day, September 29th, he was admitted to hospital, a cæcal intussusception was operated upon and reduced. The abdominal symptoms were completely relieved, but the purpura became more severe, and the hands, arms, legs, and face were covered with the eruption. Three days after the operation he complained of abdominal pain, and blood was passed per rectum on several occasions. Four days later a second intussusception developed, but the boy's condition prevented any further operation, and he died three days later with an unreduced enteric intussusception.

Henoch, in 1874, brought forward a number of cases of purpura associated with intestinal colic, vomiting, intestinal hæmorrhage, and painful swelling of the joints, and since then the condition had been recognised as a clinical entity under the name of Henoch's purpura. The case was brought before the Society in order to discuss the differential diagnosis between Henoch's purpura and intussusception, and also the diagnosis of an intussusception occurring during an attack of Henoch's purpura. That the matter was one of considerable difficulty is proved by the reporting of cases of Henoch's purpura which were operated upon as cases of intussusception, and also of cases of intussusception which occurred during an attack of Henoch's purpura, but not recognised until the patient reached the post-mortem room.

An important point to bear in mind in this connection is that not infrequently the abdominal signs, viz., paroxysmal pain, vomiting, and intestinal hæmorrhage, and even tenesmus, appear before the cutaneous lesions. Osler and others have pointed out that visceral crises might occur independently of the skin lesions. The history of a similar previous attack, however, joint pains, hæmaturia, or the vomiting of blood, should remind one of the possibility of the case being one of Henoch's purpura. In the absence of all these signs it might also be remembered that the majority of cases of intussusception occur in babies, whereas Henoch's purpura is rarely met with at that early age. Barnard found that out of 187 cases of intussusception, 135, or 72 per cent., were under one year old, while McAdam Eccles obtained a very similar result from a smaller number, *i.e.*, out of 40 cases, 27, or 68 per cent., were under one year. The joint pains are, as a rule, temporary and precede the abdominal symptoms, but they are present in a very large proportion of cases. In both conditions the pain is extremely severe and paroxysmal, but between the paroxysms the patient is fairly comfortable, though in the later stages of intussusception the pain is more continuous. A rise of temperature might be present in both, but is more frequently met with in Henoch's purpura than in intussusception. If severe vomiting be present

---

(*a*) Abstract of a paper read before the Society for the Study of Disease in Children, April 10th, 1908.

from the beginning, especially if the vomit contain blood, the probabilities are against the case being one of intussusception. Tenesmus is an early symptom in intussusception, and frequent tenesmus, with the passage of mucus and blood, is in favour of intussusception, though tenesmus does occur in Henoch's purpura. In the earlier stages of intussusception the abdomen is neither tender nor distended, and this is the rule in the majority of cases of Henoch's purpura, though a considerable number of cases of the latter disease have been described in which the abdomen was tender and distended.

Finally, Mr. Lett believed that the crucial test, and the one which should be relied upon above all others in making a positive diagnosis of intussusception, was the finding of an abdominal tumour. Statements varied as to the frequency with which a tumour could be felt. Rose and Carless considered that a tumour could be felt in about half the cases; McAdam Eccles found a tumour present in 80 per cent.; and Barnard said that an abdominal tumour would be found in 75 per cent. of the cases if an anæsthetic were given. Mr. Lett, however, thought that if a careful examination were made by the rectum and abdomen, a tumour would be found still more frequently. He had operated upon twenty-two cases of intussusception, and in every case he had been able to feel a tumour before operation, either by the rectum or through the abdominal wall. In a few cases it had been necessary to give a little chloroform before it could be found, and an examination under an anæsthetic should always be made in cases of suspected intussusception, if the tumour could not be felt. The shape of the tumour was characteristic, and during an attack of pain, or frequently as the result of manipulation, it became more definite. Hæmorrhage into the mesentery and a blood clot in the lumen of the bowel had been responsible for the diagnosis of intussusception, but these conditions were extremely rare, and the tumours thus formed had not the distinguishing features of an intussusception. Hæmorrhage into the intestinal wall rarely produced a tumour which could be palpated, and, even if it did, the consistency, outline, and size of the tumour contraindicated the diagnosis of intussusception. Intussusception did sometimes occur in the course of Henoch's purpura, and here again the diagnosis rested upon the presence of a tumour. Severe tenesmus, if present, was also a sign of considerable value. In the case he described there was a definite sausage-shaped tumour, and though the purpura was noticed, and the possibility of the hæmorrhage from the bowel being due to Henoch's purpura fully recognised, an intussusception was diagnosed from the presence of the tumour.

OUT-PATIENTS' ROOM.

GREAT NORTHERN HOSPITAL.

Congenital Œdema.

AMONGST Mr. Arthur Edmunds' out-patients was a girl, æt. 20, who applied for advice concerning a small ulcer on her right leg which had resulted from a slight injury a few weeks previously. She stated that as long as she could remember her right leg had been larger than the left, and on examination the enlargement was seen to be very marked indeed. The enlargement extended from the fold of the buttock and the groin to the toes; the external genitals were normal. The limb was not appreciably longer than that of the opposite side, but the calf measurement was about two and a-half inches more. There was a certain amount of pitting on pressure, and the patient herself had noticed a considerable diminution in the size of the leg when she rested in bed, but it never diminished to the size of the normal member. The foot was slightly tender, and about three inches above the ankle-joint there was a small ulcer with an œdematous sloughing base. The rest of the skin of the leg was perfectly normal, painless, and free from tenderness. The trunk was symmetrical, and there was no facial asymmetry, but the right arm was slightly larger than the left. This type of case, Mr. Edmunds said, is of considerable interest, although practically nothing is knows as to its ætiology. The term "trophœdema" has been devised by Henry Meige to describe a series of cases of hereditary œdema, the characteristics of which are that it is "dur, blanc et indolore." His cases were mainly congenital, and occurred in many generations of the same family; but sporadic cases exist, and in some instances the swelling only appears after an injury. Thus Etienne recalls a case where a similar œdema was produced in a young girl by breaking faggots across her knee. The present case presents, he considered, some points of dissimilarity to the typical trophœdemas, but it probably belongs to this group. Although the œdema was not absolutely hard, yet the amount of fluid which could be removed by pressure was comparatively small, and the residual solid œdema was considerable. Ulceration is not a common feature, but a limb in which there is such pronounced lymph stasis must of necessity be imperfectly nourished, and a slight injury can quite readily produce an ulcer. It is possible, also, that some of the tenderness was secondary to this ulceration. The distribution of the œdema is typical, the limitation at the gluteal fold and the absence of any enlargement of the genitals occurring in the majority of such cases; the absence also of bony enlargement is also characteristic, and distinguishes these cases from hemi-hypertrophy and from true elephantiasis. Treatment of these cases has hitherto been unsatisfactory, the diminution in size which can be obtained by massage or elevation of the limb being merely temporary, and no drugs have yet been discovered which have any effect on the swelling. The introduction by Handley of the operation of lymphangioplasty may prove of benefit in these cases, but so far the method has not been applied to them.

OPERATING THEATRES.

KING'S COLLEGE HOSPITAL.

OPERATION FOR COMPLICATIONS OF MASTOID DISEASE (continued from "Operating Theatres," January 8th, 1908, MEDICAL PRESS AND CIRCULAR, p. 42).—This was the case of a boy, æt. 14, who had been operated upon for suppurative middle ear disease, and had later on developed symptoms at first thought to be due to temporo-sphenoidal abscess, and later to cerebellar abscess. The cause of the symptoms was found after operation to be an excessive accumulation of fluid in the lateral ventricles. When the case was last described the boy had a discharge of foul-smelling pus from the cerebellar trephine opening. This discharge gradually ceased and the boy began to improve in strength and in general condition. In about a week's time he suddenly became comatose, with Cheyne-Stoke's breathing and considerable pallor of the skin. He was, of course, quite unable to take nourishment. It was noted that there was some dulness at the bases of both lungs; this was at the time supposed to be due to hypostatic congestion. The general condition was much too precarious to admit of any further operative procedures, as it was quite clear that it would be impossible to give him an anæsthetic. Three days later he died. At the post-mortem examination the dulness which had been observed at the bases of both lungs was found to be due to the presence of infarcts. On removing the brain it was evident that there was considerable flattening of the cerebral convolutions, but there was nothing to mark where the cerebral hemispheres had been freely explored with the finger in the temporo-sphenoidal region. The left cerebellum was normal, and everything pointed to the fact that the mastoid disease on the left side had been completely removed. The right cerebellum was in a state approaching liquefaction, there was really very little of it remaining; on exploring it some very thick greenish-yellow pus was found coming from the region of the temporal bone, and on investigating this bone a considerable quantity of the same kind of pus was found in contact with it. Mr. Beale said that during life there was nothing to indicate the presence of this pus until coma supervened; it would be remembered that many weeks previously there were symptoms of a right cerebellar abscess, and after trephining the right cerebellum a large amount of fluid was removed from the right lateral ventricle, and after this the symptoms entirely abated. Later on the boy had several attacks of severe headache, but there was not at any time any unusual rise or fall of temperature, nor were there any localising symptoms. The cerebellar wound was being drained up to the time of the boy's death. The wound which had been made to drain the right middle ear and mastoid region was also open. He could, therefore, but assume that the pus had been accumulating between those two wounds, probably close to the petrous portion of the temporal bone, but it produced absolutely no symptoms until the boy became comatose, when, as before stated, he could not possibly from his general state and from the condition of his lungs have taken an anæsthetic. Mr. Beale pointed out that the pus might have been present when the right cerebellum was trephined and that, although the cerebellum was fully explored and the lateral ventricle was tapped through the trephine opening, the pus was not detected. Though these procedures removed all the symptoms of cerebellar abscess, it did not follow that there was no abscess, for the relief of tension might account for the disappearance of the symptoms. At the same time, if the pus was present it was a very remarkable fact that it did not find its way out through the cerebellar wound. On the whole, he was inclined to believe that the abscess which caused the boy's death was of the nature of a residual abscess, due to imperfect or incomplete drainage.

ROYAL FREE HOSPITAL.

Fracture of Skull in Left Occipital Region.—Mr. T. P. Legg operated on a middle-aged man who had been brought to the hospital in a profoundly unconscious condition. He was said to have fallen from a cart, and when seen soon after admission the following signs were present:—There was an irregular wound in the left occipital region; the bone could not be felt by a probe; his breathing was slow and stertorous; the pulse was 48 per minute, full and regular; the right pupil was dilated, the left was small; both failed to react to a strong light; there was some drooping of the left angle of the mouth, and it seemed as if the left arm and leg were more flaccid than the right limbs; there was no hæmorrhage from either external ear, or in the mouth, or in the nose; there was some fulness in the sub-occipital region on the left side, and this suggested a deeply situated hæmatoma. The symptoms and signs were typical of cerebral compression due to hæmorrhage, which might be either extra-dural or sub-dural. Mr. Legg said it was noticeable that there was no history of a "lucid" interval after the accident, but no one saw the accident or knew how long it had happened before the man was found; probably it was only a short time. Operation was undertaken on the possibility of the hæmorrhage being extra-dural, though it was recognised that the chances of being able to save the patient's life were remote. The wound in the occipital region was excised, and a flap of all the extra-cranial tissues turned downwards. A fissured fracture was seen running upwards towards the vertex and downwards to the base of the skull. A trephine was applied to one side of the line of the fracture, and on removing the disc of bone no extra-dural hæmorrhage was found, but instead of the dura being white, it was bluish in colour, which meant that the hæmorrhage was effused on to the surface of the brain. Moreover, the latter did not pulsate at all. It was therefore decided to complete the operation by sewing together the margins of the flap. Mr. Legg remarked that this case raised several important points as regards diagnosis, and especially treatment. That the man was suffering from cerebral compression due to hæmorrhage was obvious; the main question was whether the hæmorrhage was intra- or extra-dural, or in both situations, as was so commonly the case. The absence of a "lucid" interval after the accident suggested that the hæmorrhage was intra-dural or intra- and extra-dural. It was often impossible to tell in which position it was situated without trephining, and therefore he thought that if there was present any localising signs or a wound, operation was the best procedure, provided also that the pulse and aspect of the patient did not suggest he was actually dying. If there was nothing to guide one where to operate, nothing should be done, and in all cases it must be recognised that the prognosis was very bad. The signs in this man suggested he had a hæmorrhage on the right side, but the wound should be always explored in the first instance, and then, if there was not sufficient to account for the symptoms in the region of the wound, trephining should be done at the place indicated by the signs. This man was found to have an intra-dural hæmorrhage in the occipital region, and as this was evidently only part of a large general intra-dural hæmorrhage, a second trephining in another place on the right was not indicated. When the hæmorrhage is intra-dural, Mr. Legg pointed out, it is seldom advisable to open the dura, because the blood is in the meshes of the pia; it cannot be removed, nor can the bleeding spots be usually found, for, as a rule, the hæmorrhage comes from the contused brain substance. Mr. Legg remarked that too much reliance must not be placed on the difference in the size of the pupils. From their inequality it may be inferred that there is greater compression on one side than the other, and perhaps the larger pupil is on the side of the greater amount of blood. But their condition does not help one to diagnose an intra- from an extra-dural hæmorrhage. He also pointed out that a fissured fracture in the occipital region generally extended into the base of the skull, and though this man had no external signs of such an injury, he had probably sustained this fracture. In these injuries, also, there was frequently laceration of the frontal lobes of the brain by *contre-coup*.

The man died soon after the operation had been completed. At the post-mortem a fracture of the base of the skull extending into the left middle fossa and skirting the foramen magnum was found. There was a large hæmorrhage over the convexity of the brain, and a laceration of the frontal lobe. There was no extra-dural hæmorrhage.

The sum of £111 has been subscribed by friends and supporters of the Hertford General Infirmary for a testimonial to Dr. J. T. Tasker-Evans in recognition of his valuable services to the institution for the long period of 29 years as honorary medical officer, a position he has now resigned.

TRANSACTIONS OF SOCIETIES.

HARVEIAN SOCIETY OF LONDON.

Meeting held April 9th, 1908.

The President, Mr. D'Arcy Power, in the Chair.

Mr. Louis B. Rawling read a paper entitled

THE SURGICAL TREATMENT OF THE INCOMPLETELY DESCENDED TESTIS,

based on an investigation of 120 cases admitted into St. Bartholomew's Hospital during the past five years. The conditions prior to and at operation were alluded to, and it was shown that the almost constant presence of a peritoneal process added to the necessity of operative treatment. In dealing with the question of the treatment of the affected testis, those cases were first discussed in which one organ was normally placed whilst the other was incompletely descended. Scrotal placement was attempted in 40 cases, in 29 of which the ultimate result was observed. In 25 of these the late result was unfavourable, the testis either retreating to the pubo-scrotal, pubic, or inguinal regions, and becoming small and atrophic. In 4 cases only was the result at all favourable. The remaining cases could not be traced, though in three the early result showed that only failure was to be expected. For these and other reasons it was obvious that scrotal placement, except in the most favourable cases, was doomed to failure from the very beginning. The three alternatives—to allow the testis to remain in the inguinal region, to replace it in the abdomen, and to remove it altogether—were then considered. All evidence pointed to the fact that the inguinal testis was a source of great discomfort to the patient, and that it was more than usually liable to infection, torsion, and malignant disease, whilst the uselessness of the replaced testis from a spermatogenetic point of view was generally acknowledged. In 50 cases the testis was removed, the patients being of all ages, and it was apparent that the removal of the one organ in no way interfered with the development, mental or physical, of the patient, and the procreative powers were in no wise impaired. The normally placed testis fulfilled all the desired functions, internal and external.

Granting, therefore, that due time was allowed for the further descent of the organ, and that exposure showed that scrotal placement was out of the question, it was advisable that the affected organ should be removed and the inguinal canal sewn up.

Attempts to place the testis in the scrotum offered the best chance of success when the operation was carried out after seven years of age and well before puberty.

With regard to double failure in descent, it appeared necessary that every effort should be made to place the testes in the scrotal region, for the examination of testicles removed showed that the spermatogenetic functions were more active when the organ was in that position than when abdominally replaced. All evidence showed that the abdominally replaced testes were functionless, from a procreative point of view, and double abdominal replacement was therefore most inadvisable. In case of failure in scrotal placement it was even preferable that the testes should be allowed to remain in the canal rather than that they should be abdominally replaced.

Mr. Edred M. Corner also contributed a short paper on the subject, which will be found in another column on page 474.

The President said that it was important to distinguish between a useless and a partly developed testis. In the former case removal was advisable; in the latter replacement should be effected. He spoke of the unsatisfactory results following the operation of scrotal placement with orchidopexy.

Mr. Eccles considered that it was most important to bear in mind the property of the testis in producing an internal secretion, even when its procreative function was lost. For this reason removal should not be carried out in cases where there were grounds for thinking that the organ might have some function from its internal secretion unless the other organ were well developed. In adults removal of the imperfectly descended organ was often advisable. He considered that the operation of orchidopexy and scrotal placement was generally unsuccessful, because retraction usually occurred. He suggested a method of relieving the tension on the cord by unlooping it round the epigastric artery; this procedure considerably diminished the retraction following scrotal orchidopexy. He did not consider that the occurrence of malignant disease in an undescended testis was so common as had been stated.

Mr. Laming Evans criticised the accuracy of the statistics as to the occurrence of imperfect descent of the testis.

Mr. Lawrence Jones insisted on the importance of early operation when scrotal placement was undertaken.

Mr. Ivor Back believed that when an operation was undertaken, removal of the undescended testis was the best course to adopt.

Mr. Campbell Williams believed that orchidopexy was very unsatisfactory as regards any further development of the fixed organ.

Mr. Crisp English said that in many cases where the testis was undescended the best course to adopt was to avoid operative interference. When the condition became complicated by hernia, or local disease, an operation became necessary.

Dr. Kenneth Lees and Dr. Claye Shaw discussed the advisability of the operation of removal of the organ from a psychical point of view.

Mr. Rawling replied.

Clinical cases were also shown at the meeting:—

(1) A case of ruptured aortic valve, by Dr. Kenneth Lees.

(2) A case of ataxy of acute onset in association with tabes dorsalis, by Dr. Carmalt Jones.

(3) A case of arterio-sclerosis with retinal changes following parenchymatous nephritis in a boy, æt. 9, by Dr. W. H. Willcox.

(4) A case of scrotal tumour, by Mr. Crisp English.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

Meeting held Friday, April 10th, 1908.

Dr. E. Hobhouse in the Chair.

Mr. Hugh Lett read a paper on a case of "Henoch's Purpura associated with Intussusception." The patient, a child of 3, was quite well until two days before his admission to hospital. He then had pain and swelling of the left knee and elbow. The next day both legs were swollen, and he had severe paroxysms of abdominal pain. The same afternoon two purpuric spots were seen on the left leg. He was admitted the following morning, and a cæcal intussusception operated upon and reduced. The purpura steadily became worse, and he finally died from a second intussusception of the enteric variety nine days after the first operation. Mr. Lett drew attention to the difficulty often met with in diagnosing between intussusception and Henoch's purpura when the abdominal symptoms appeared before the onset of any cutaneous lesions, and also to the difficulty in many cases of undoubted Henoch's purpura of deciding whether an intussusception were present or not. After a survey of the literature, he indicated the main points in the differential diagnosis between the two conditions, and laid stress on the importance of determining the presence of a tumour before making a diagnosis of intussusception. (An abstract of this paper will be found on page 475.)

Dr. G. A. Sutherland thought there was a special form of gastro-intestinal hæmorrhage associated with Henoch's purpura. All the signs of intussusception might be present, with the exception, perhaps, of a palpable tumour. Further, he, like the reader of the paper, had had experience of the occurrence of intussusception in Henoch's purpura. He thought that the diagnosis of spontaneous reduction, made sometimes after the abdomen had been opened, might be reserved for those cases in which no evidence of hæmorrhage was present. For if hæmorrhage were present he should regard it as a sufficient explanation of the symptoms.

Mr. Duncan Fitzwilliams said that the presence of a tumour settled the diagnosis in practically every case. He thought that it was possible to recognise the presence of a tumour in 85 to 90 per cent. of cases in infants, if careful examination were made under an anæsthetic.

Dr. J. Porter Parkinson read a paper on a case of "Tetanus Neonatorum." The patient, an infant of two weeks, had been ill for four days. The mother had had several other children, and one had died when six days old from "lockjaw"; he was unable to take the breast, and was said to have had similar symptoms. On admission to hospital there were general rigidity and opisthotonos, also a well-marked risus sardonicus. The umbilicus looked unhealthy, and discharged a thin, sticky fluid. The child improved, but died suddenly from asphyxia 17 days after admission. It was discovered that the mother had treated the umbilical wound with Fuller's earth, and it was suggested that this might have been the cause of infection both in this child and also in the previous child who had died from tetanus. Dr. Parkinson drew attention to the prevalence of this practice, and to the fact that this possible source of tetanus was well recognised by coroners. He thought that the knowledge of this should be more widespread.

Dr. Cautley and Dr. Carpenter discussed the paper.

A Member said that he had a large practice among the poorer classes, and Fuller's earth was used by probably 95 per cent. of mothers. To attribute the disease to that was, he thought, casting an undeserved reflection on the preparation.

Dr. Leonard Guthrie showed a case illustrating Eustace Smith's bruit. The patient was a boy, æt. 7. The superficial veins were enlarged over the front of the chest. On auscultation an undulating musical venous bruit could be heard at the base of the heart, occupying the whole of the cardiac cycle. The bruit was intensified and the venous engorgement became more pronounced when the head was retracted. The condition was probably due to pressure of enlarged mediastinal glands on the innominate vein, or superior vena cava.

Dr. Langmead showed a case with Eustace Smith's bruit. The patient, a girl, æt. 5½, had whooping-cough in April, 1907. Since then she had had frequent coughs, which were neither laryngeal nor paroxysmal. There was some impairment of note in the interscapular region on the right side. To the right of the manubrium sterni, a definite to and fro rushing murmur was heard when the head was retracted, but it was lost when the head was flexed.

Dr. Guthrie, in reply to discussion, said he thought he could diagnose the condition by other physical signs—namely, diminution of resonance to the right of the sternum in the second and third spaces, and by the character of the breath sounds. The breath sounds were almost tracheal in character, and were heard behind as well as in front. Spasmodic cough was a very prominent symptom, and was frequently regarded as whooping-cough.

A case of "Aortic Regurgitation" in a boy, æt. 4, was shown by Dr. Porter Parkinson. He was brought to the hospital for fainting fits. There was no history of rheumatism or other acute specific fever. The cardiac impulse was in the fifth space just outside the nipple line. There was a well-marked diastolic murmur at the base of the heart, best heard on the left side, and conducted down the sternum. The pulse was regular and collapsing. Capillary pulsation was well marked.

A case of "Recovery from Encephalitis" in a girl of 1 year and 8 months was shown by Dr. George Carpenter. Three weeks before the onset of the attack she had had measles. When admitted to hospital she had screaming fits, double optic neuritis and squint; the temperature was sub-normal. Lumbar puncture was followed by an abundant flow of fluid, which was sterile, and contained no cellular elements. She ultimately recovered completely, except that she was perhaps not so bright as she had been before the illness. The optic neuritis disappeared.

The Chairman said that lumbar puncture was of interest in such cases. It was frequently performed for suspected meningitis, and the symptoms disappeared. In one case in which there was marked retraction of the head the condition cleared up. It followed pneumonia, and pneumococci were found in the fluid.

A case of "Hypospadias" was shown by Mr. Hamilton Burt.

The heart of a child, æt. 7, with "Infective Endocarditis of the Pulmonary Valves," probably supervening on congenital disease, was shown by the Chairman. As the result of ulceration there was a communication with the aorta. In life there had been a very loud, harsh, and almost continuous bruit.

The stomach of a child, æt. 3½, who had died from tetany was also shown by the Chairman. The stomach was very small, and there was no dilatation of the colon.

Specimens from a case of "Bilateral Renal Apoplexy" were shown by Dr. Edmund Cautley. The patient, a boy of 3 months, died after an illness of two days' duration, characterised by convulsive movements and unconsciousness. There was no apparent cause for the condition.

A specimen from a case of "Congenital Morbus Cordis" was shown by Dr. George Carpenter.

A specimen and skiagram from a case of "Traumatic Separation of the Lower Epiphysis of the Femur" in a lad, æt. 14, were shown by Mr. John Poland. The diaphysis was displaced outwards and backwards without injury to the popliteal vessels. The specimen showed the appearances at the end of 38 days after the injury. The new bone deposited between the displaced epiphysis and stripped-up periosteum in front of the diaphysis was particularly to be noted.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held April 9th, 1908.

Cases.

Dr. F. S. Heaney reported a case of "Malunited Fracture of Leg Bones" on which he had operated twice. The fracture of the tibia was spiral and comminuted, and, in spite of careful treatment, some 14 weeks after the injury the lower fragment of this bone was found united with the upper fragment of the fibula. The fracture was identical with one shown by Mr. Lane in his recent work on fractures, and the same peculiar vice of union had supervened in both cases, as well as in others that had come under observation. In the present case union had been brought about by screwing and wiring. Dr. Heaney advocated operation in all such cases in the first instance.

Mr. Newbolt was of the opinion that all cases of compound fracture of the tibia and fibula should be operated on as soon as possible.

Mr. R. C. Dun reported a case of "Acute General Peritonitis" in a child, æt. 4, the result of perforation of a typhoid ulcer in the lower ileum. The sudden appearance of acute peritonitis was the first indication of illness. The diagnosis of acute appendicitis with peritonitis was made. At the operation no cause for the peritonitis was found. The child lived 12 hours after the operation, and at the post-mortem definite changes, characteristic of typhoid in Peyer's patches, were found. A small perforation through an ulcer was present 4 ft. from the ileo-cæcal valve. Mr. Dun commented on the rarity of typhoid at that age, and especially perforation, the fact that there were no symptoms of illness until the perforation took place, and the difficulty of making an accurate diagnosis in such a case.

Dr. P. Marsh thought it quite possible for a child to have an attack of ambulatory typhoid as met with in adults. He agreed that typhoid is very rare in children so young, and especially perforation.

Mr. Paul gave his experience of Butlin's operation for cancer of the tongue and mouth during the three years since Mr. Butlin's lecture had been published.

The total number of cases was 35. Lip, 3; cheek, 3; palate, 1; tongue, 28. Of these 11 were favourable in size and situation, 15 were advanced cases, and 9 involved the bone. Of the favourable cases 9 were free from recurrence, 1 died from operation, and in 1 no report was obtained (a slight case). Of the advanced cases 8 were free from recurrence, 1 has recurrence, 5 died from the disease, 1 no report. Of the bone cases, none are known to be free, 4 have recurrence, 1 died from operation, 2 from disease, and 2 no report. Altogether, 17 free, 5 recurrence, 7 dead of disease, 2 of operation, 4 no report. Those free have been operated on in years and months, respectively—3.4, 3.0, 2.11, 2.11, 2.10, 2.5, 2.2, 1.10, 1.9, 1.7, 1.3, 1.2, 1.1, 0.5, 0.4, 0.4, = 17.

Mr. Paul strongly advocated a definitely planned attack on the glands in all suitable cases of cancer. He previously thought, and he believed most surgeons thought, that they had fully recognised the importance of this for several years. But it was one thing to accept a general principle and another to adopt a definite plan of attack, and since he had carried out thoroughly the details of Butlin's operation on the neck his results in tongue cases had been infinitely better than they ever were before.

BRACHYDACTYLIA—A STUDY IN HEREDITY.

Dr. H. **DRINKWATER** read a paper on the above subject, giving an account of a brachydactylous family. The chief defect in these people consists of an abortive condition of the middle phalanx in all the digits, both of hands and feet. Sometimes in the middle and ring finger this middle phalanx is reduced to a small cubical bone, but in most instances it has become ankylosed to the ungual phalanx. In no instance is it seen as a separate bone in the first or fourth finger or toe. The first phalanx of the thumb is greatly shortened, and in young children shows no sign of an epiphysis. In this respect it has undergone precisely similar changes to the middle phalanx of the fingers. The epiphysis of the so-called metacarpal bone of the thumb is at its base, whereas that of the other metacarpals is at the distal end. This shows that the metacarpal bone of the thumb is in reality the first phalanx, and that the first phalanx is homologous with the second phalanx of any other digit. The same holds good for the big toes. The metacarpals are all short and undulated at the distal ends. There are 25 people living belonging to one family who show these defects. The stature and the finger measurements of the abnormals of these families are always less than the "normals." The hands and feet are always symmetrically affected. They are prolific with from 8 to 17 children in a family; one woman has had 99 descendants (three generations). The fecundity of the woman exceeds that of the men. There is not a single abnormal individual over 23 years of age who has remained single, whilst among the normal relatives more than a dozen have remained single. The defect has been traced through seven generations, comprising 174 individuals. Among the children of abnormal parents the defect is found in over 50 per cent., thus agreeing with Mendel's law of inheritance. The children of normals are in every instance normal. The deformity prevents the abnormals from learning trades requiring manual dexterity. They are all English.

Dr. T. **BRADSHAW** said that the great point of interest in the paper, from the view of the physician, was the possibility of the inheritance of the disease taking place on Mendelian lines, so that we could in many cases assure our patients that unaffected individuals need have no fear of transmitting a family disease to their posterity. Unfortunately, there were many diseases which were clearly transmitted by unaffected people, as was shown by Dr. Gossage in the current number of the *Quarterly Journal of Medicine.*

Dr. R. J. M. **BUCHANAN** thought that the study of heredity in disease was important in that it might throw light on the ætiology of diseases about which we still remain more or less ignorant. He had found a tendency to hereditary transmission in pernicious anæmia, and quoted an instance he had met with of a mother and two sons having died from this disease; there seemed to be an hereditary tendency in the splenic anæmia of adults.

Dr. **HUBERT ARMSTRONG** recalled a family of which some years ago he had been able to show before the Institution several members in three generations. The deformity in these was microdactylia, and their hereditary history was very similar to that of Dr. Drinkwater's series, and the deformity was also symmetrical.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD FRIDAY, APRIL 10TH, 1908.

The President, Dr. A. J. **WALLACE** (Liverpool) in the Chair.

DR. **ALEXANDER STOOKES** (Liverpool) exhibited two specimens—(1) Fibromyoma uteri, (2) adeno-carcinoma corporis uteri, which presented similar physical signs. The former occurred in a patient, ii.-para., æt. 43, who had suffered for two years from menorrhagia, and for the last four months had continuous bleeding. A nodular tumour could be felt in the lower abdomen, and per vaginam a polypoid mass occupied the cervical canal. The growth proved to be multiple fibromata. The second specimen occurred in a single woman, æt. 51, who had enjoyed good health until 18 months ago, when she began to have severe pains in the left side and menorrhagia. These symptoms persisted. An irregular hard tumour was felt in the lower abdomen, which on abdominal section proved to be the uterus enlarged by adeno-carcinoma, involving the entire thickness of the uterine wall. The right ovary was also the seat of adeno-carcinoma. Recurrence with a fatal result occurred four months after the operation.

Dr. **BRIGGS** communicated a case of pelvic kidney with congenital absence of both Mullerian ducts occurring in a patient, æt. 33, one year married, who complained of occasional, never periodic, pain in the lower abdomen, and slightly increased frequency of micturition. She had never menstruated. On physical examination she was a healthy, intelligent woman. The breasts were rather small and the pelvis somewhat undersized. No abdominal tumour could be found. The vagina, 1¼ in. in length, ended in a loose cul-de-sac, beyond which the lower pole of a pelvic tumour could be felt. Per rectum the tumour felt to be partly in front and partly to the left of the rectum, but the fingers could not reach to the upper limit of the tumour.

On abdominal section, the left kidney was visible, lying totally within the pelvis against the bladder, to which a 1-in. ureter passed. It was one-third larger than normal. The hilum was directed upwards and to the right, so as to face the direction of the renal vessels. A superficial vein 3 inches longer passed to the vena cava, and covered the renal artery, which was apparently derived from the bifurcation of the aorta, and corresponded in site of origin to a very large middle sacral artery. There was no kidney in the loin of the same side. The right kidney was two-thirds of the normal size. The total absence of uterus, Fallopian tubes, or ovaries, or any representation of them, was manifest. The disposition of the peritoneum was traced—

(*a*) From the bladder in front to the rectum behind, as a smooth pouch, with the deepest portion barely reaching the vaginal cul-de-sac.

(*b*) The kidney was fixed in the pelvis, and curved in front by the peritoneum.

(*c*) The rest of the pelvis was lined by a smooth peritoneum devoid of folds.

The operation was barely exploratory.

Dr. **ARNOLD W. W. LEA** (Manchester) narrated a case of "Dermoid Cyst" of the mesentery, and showed the specimen and sections. The patient was an unmarried woman of 39, who complained of colicky abdominal and hypogastric pain and vomiting. Menstruation was regular. There was frequent micturition. Per vaginam, a tumour the size of a fœtal head could be made out, which on abdominal section proved to be a cyst of the mesentery. Removal by enucleation was carried out. The cyst was lined by large multinucleated cells, but did not show any specialised epithelial elements.

Sir **William Sinclair** (Manchester) read a paper on

ANALGESIA VERSUS ANÆSTHESIA IN OBSTETRICAL AND GYNÆCOLOGICAL PRACTICE.

He reviewed the various means adopted to mitigate pain in the Middle Ages, including the use of wine and concentrated alcohol for operations in time of war. In the practice of midwifery there did not appear to be any method employed to relieve pain at that time. The difficulty of obtaining an anæsthetic that did not interfere with the progress of labour was recognised. There were well-known drawbacks to the administration of ether and chloroform. Reference was made to spinal anæsthesia produced by cocaine and its derivatives, and to the inadvisability of such procedure in obstetrics.

A few years ago great successes were reported from the Lying-in hospitals of Germany from small doses of scopolamine, but this was not without real danger to both mother and child. The speaker went on to advocate the use of a combination of morphia, alcohol, and cocaine as an analgesic in minor gynæcological operations, and in such manipulations as the removal of retained placenta following abortion, etc. He gave 2 oz. of alcohol, masked by the liquid extract of liquorice, about two hours before operation, followed by a hypodermic injection of ¼ or ⅓ gr. of morphia, 20 minutes before the operation. The vagina was then swabbed with a 10 per cent. solution of cocaine. By this method any minor operative procedure was possible. The amount of morphia required modification according to the type of patient. In some cases where a general anæsthetic was necessary, the amount required was exceedingly small, if morphia and alcohol were previously administered.

Dr. **Knyvett Gordon** (Monsall) had used this method of producing analgesia in a large number of cases in which, on account of the serious condition of the patient, a general anæsthetic was contra-indicated—*e.g.*, in vaginal operations in advanced puerperal sepsis.

Dr. **Arnold W. W. Lea** (Manchester) also spoke in favour of this method. He had employed it in painful obstetric manipulations—as, *e.g.*, the removal of a macerated fœtus from a patient with advanced cardiac disease. He attached importance to the influence of suggestion in producing analgesia.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Clinical Evening held April 3rd, 1908.

The President, **Richard Lake**, F.R.C.S., in the Chair.

The following cases were shown:—

Dr. Chas. W. Chapman: A case of aneurysm of the arch of the aorta, with dilated veins over the chest and abdomen.

Dr. Arthur Saunders: A case of congenital syphilis.

Dr. F. G. Crookshank: A stained film of cerebro-spinal fluid from a case of cerebro-spinal meningitis.

Mr. Duncan C. L. Fitzwilliams: (*a*) A case of congenital absence of fibula and outer two toes. (*b*) A radiograph showing congenital absence of radius and thumb. (*c*) A case of mal-development of the fingers of the right hand. (*d*) A case of scoliosis due to accessory (?) vertebra. (*e*) A case of congenital asymmetry of face, dermoid (?)

Mr. Percy Dunn: A case of unusual ocular paralysis.

Mr. John Pardoe: A case of Charcot's disease of the knee-joint.

Mr. Donald Armour: A case of tumour of testicle in a man, probably malignant.

Mr. Aslett Baldwin: (*a*) A case of malignant tumour of submaxillary gland in a man, æt. 65. (*b*) A case of enchondromata of bones of hand in a boy. (*c*) A case of congenital syphilis in a girl. (*d*) A case was described of successful operation for removal of malignant growth of tonsil and surrounding parts. The case could not be shown as the patient (a woman) had been readmitted to the hospital for a perforated and gangrenous appendix, and had undergone a second operation for intestinal obstruction, but was progressing favourably.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD

FRANCE.

Paris, April 26th, 1908.

Criminal Abortion in France.

It is well-known that the natality in France is exceedingly low—much lower than any other European nation; and this fact led the Germans to say that "France loses a battle every year."

The reasons of this abnormal condition are complex, but, for practical purposes, might be reduced to two main factors—the practice of Malthusianism and criminal abortion.

The limitation of families is general, especially in the large towns, where the complications of living are great and form the exciting cause. Purely selfish motives, however, are not foreign to this culpable practice. Criminal abortion is not infrequently due to the same causes, but it is more particularly practised to hide a fault.

Prof. Boissard, of the Tenon Hospital, has uttered recently a cry of alarm as to the increasing number of criminal abortions in France. The percentage of abortions treated in the Paris hospitals had risen from 6 to 18 per cent. between the years 1898 and 1904, and is still increasing. M. Boissard said that he was convinced that two-thirds of the total number of abortions were due to criminal practices.

Prof. Lacassagne, of Lyons, writing on the same subject, said that abortions were more numerous than births. There are 150 midwives practising in Lyons. One related that she had attended at least three miscarriages a week, or about 150 a year. If, to take the average, 100 midwives attended 100 abortions each in the year, the total would be 10,000. As the natality of the second city of France is from 8,000 to 9,000 per annum, it follows that the number of abortions exceeds that of births. Thanks to antisepsy and the cleverness of the women who practise this criminal industry, abortion can be provoked on a large scale and without much risk.

Exophthalmic Goitre.

The treatment by sulphate of quinine of exophthalmic goître is recommended by Prof. Lancereaux. The fundamental trouble in this disease being the vaso-dilatation of the blood-vessels of the neck and head, M. Lancereaux estimated that quinine, by reason of its vaso-constrictive properties, should have a favourable effect. It was thus that he treated over 20 patients by 10-grain doses of quinine sulphate, given twice a day for several months, with intervals of rest. Under its influence the vaso-dilatation phenomena ceased, as well as the nightmares, tachycardia, exophthalmia, and even the goître considerably diminished.

Pigmentary Nævi.

Several cases of pigmentary nævi, treated and cured by the action of radium, were presented by M. Mazotti before the Medical Society. The cicatrices were soft and smooth; both the hairs and colouration had disappeared. These results are the more remarkable, as these kind of nævi had hitherto been rebellious to all treatment.

Atrophic Cirrhosis of the Liver.

The patient should be kept in the recumbent position the greater part of the day, and placed on milk diet.

As medical treatment, iodide of potassium should be prescribed for weeks:—

Iodide of potassium, 1 dr.
Sulph. of strychnine, ⅛ gr.
Water, 10 oz.

A tablespoonful twice a day.

As a stimulant to the biliary secretion, salicylate of soda might be given, but many patients ill support this drug. In such cases it may be replaced by benzoate of soda associated with jaborandi:—

Benzoate of soda, 5 gr.
Phosphate of soda, 10 gr.
Powdered jaborandi, 2 gr.

For one wafer; two daily in an infusion of boldo.

Each evening an aloes pill should be taken.

In certain patients oliguria is frequent, and in such cases theobromine associated with phosphate of soda, which increases its activity, succeeds frequently:—

Theobromine, }
Phosphate of soda, } āā 10 gr.

For one wafer. One every hour until three have been taken. In case of non-success, the following pills:—

Powdered squill, 1 gr.
Powdered digitalis, 1 gr.
Powdered scammony, 1 gr.
Two to four pills in the 24 hours.

Hæmorrhage is the gravest complication of cirrhosis of the liver. It is best treated by rest, repeated injections of serum, and the administration of chloride of calcium.

GERMANY.

Berlin, April 26th, 1908.

The Ætiology and Pathogenesis of Epityphlitis.

This subject was discussed at the Verein für Innere Medizin, on the introduction of Hr. v. Hansemann, who read a paper on the subject.

He began with some general observations. One could not contemplate the important ætiological discoveries in regard to a large number of diseases during the past thirty years without a certain feeling of unpleasantness. Causes for diseases of all kinds had been discovered, but it was soon seen that these causes did not apply to all cases, or that they were met with in other diseases, and even in people who were healthy. Disputes took place on the subject amongst medical men, which were often decided by a majority of votes, until at last the idea gained ground that all was not lasting. These phenomena rested on an imperfect mode of thinking. We always looked for the causes of diseases, when we ought to determine the conditions under which they made their appearance. He would follow this mental process in regard to the theme to be discussed.

What were the conditions necessary for the occurrence of epityphlitis? Parasites and foreign bodies were named in the front rank as causes. But against this was to be objected that parasites scarcely came into consideration as primary causes. In only one case in the human subject had he seen the oxyuris vermicularis in the vermiform appendix, and once in an ape he had found the head of a tapeworm, and in both cases in a healthy intestine. It was the same in regard to foreign bodies; it was only exceedingly rarely that they were present in the vermiform appendix, and when they were present they were not the exciters of inflammation. Naturally foreign bodies were found now and then, but they could even penetrate through the walls of the intestine without setting up peritonitis, without setting up any inflammatory symptoms at all. (Here a fish-bone was shown that had penetrated the wall of the intestine, found accidentally at the autopsy.) These two factors could therefore be excluded as exciters of epityphlitis. It was the same with coprolites, which were not causes of inflammation, but were more likely developed by the inflammation.

An important condition for the development of epityphlitis was the presence of pathogenic bacteria—a condition that was always antecedent. *Per se*, however, they were not to be considered as a direct cause. We must distinguish two groups of bacteria—(1) the ubiquitous, which were always to be found in the intestines—they acted as exciters of inflammation only under special circumstances; (2) such bacteria as were only exceptionally present, such as the bacilli of tubercle and influenza, and others. In certain cases they might be the primary exciters of inflammation. In times of influenza epidemics, epidemics of epityphlitis had been known to have been caused by influenza bacilli. With regard to other bacteria, however, such as the bacteria of suppuration, further conditions must be present for the onset of inflammation.

An important *rôle* favourable to inflammation had been attributed to the lymphatic apparatus of the vermiform appendix. The bacteria were said to be captured in the follicles, and to have then worked their mischief. At the present day, however, considering the structure of the vermiform appendix as the result of retrogressive development in the human subject, the lacunæ were not so much looked upon as capturers of bacteria, and if these did get in they also got out again.

For the ubiquitous bacteria mentioned above to act as exciters of inflammation, other conditions were necessary, and, above all, stasis, as we could observe also in other organs. The inflammations associated with stenosis of the pylorus, with gall-stones, and those associated with diminished power of emptying the bladder might be recalled to memory. Even in closed cavities we observed the same conditions—for example, the peritoneum, in which bacteria were otherwise rendered harmless by absorption. A similar condition was present only occasionally in the vermiform appendix. It was interesting to compare the conditions in infants, children and adults. In the former the vermiform appendix had a funnel-shaped opening into the cæcum; this became narrower later on; it sometimes persisted, however. With such a wide opening, perityphlitis did not occur, with the exception of those cases in which tubercle bacilli were present. The significance, also, of the valve of Gerlach was not properly recognised. The appendix was very movable, and the valve would be open or closed according to its position. It might happen that bacteria might enter through an open valve and find themselves in a closed sac from a change of position of the appendix, and they might then develop their pathogenic properties. Inflammation of the cæcum, the typhlitis of earlier authors—the existence of which had been denied, but unjustly, as it undoubtedly occurred, set up by fæcal accumulations and other causes—played an important *rôle*, as the opening of the vermiform appendix was closed by swelling of the mucous membrane; it might then be converted into a closed sac. Tuberculous changes in the cæcum might also shut off the opening through swelling of the mucous membrane.

From all this it was explainable why inflammation of the vermiform appendix was so rare in children. It also explained the rarity of the occurrence in old people, who would have had the disease earlier in life if they had had a predisposition to it. It also explained how somatic conditions might have an influence on the origination of an epityphlitis, such as pressure in straining, gymnastics, etc. By causing a change of position of the vermiform appendix, closure of it might be brought about. Remains of recoveries from inflammation of the organ were frequently found accidentally at autopsies. They might favour a disposition to recurrence of the disease.

Practically, the most important point was the prognosis, to know whether the appendix must be removed or whether the attack should be allowed to run its course. Undoubtedly, extirpation was done too frequently, as not infrequently little, or even no disease at all, was found on the extirpated organ. In the latter case the disease had been seated in the cæcum. This might be successfully treated after removal of the vermiform appendix. In general we must concede that we did not know what would happen in any given case. A vermiform appendix might also become obliterated without inflammation by so-called senile involution. The obliteration caused by inflammation and that set up by senile involution were to be distinguished; in the former case the obliteration began at the opening; in the latter at the apex.

AUSTRIA.

Vienna, April 26th, 1908.

Antagonism of Poisons.

These may either be chemical or physiological. Meyer declared at the Gesellschaft the former produces an innocent compound, while the latter is more complex in its action, and not so reliable, owing to the indefinite action of the poison and antidote. The chemical treatment is easy, as all can understand the result of an alkali and acid when brought together, but with an organic poison and its antidote the neutralising action is not on each other, but on the effects of each other, such as atropine on pilocarpine, the former paralysing the action of unstriated muscle and the heart, while the latter stimulates. In the greatest number of cases the inhibitory action of the drug is first observed, although the stimulating property is not infrequently observed. When the central system is involved, the difficulty is increased; for instance, morphia and hydrocyanic acid, which are paralysers, will be difficult to arouse with atropine, which is a stimulant in this case. Again, chloral-hydrate and alcohol produce paralysis, while caffein, or a mixture of morphia and picrotoxin would be the antidote. The rise and fall of temperature is another difficult action to control. Where two motor fields are awakened, the one to liberate, the other to restrain the impulse, the resulting action is very difficult to determine.

We have yet another complication to consider in the vegetative nerve system or the involuntary, as vessels, glands, and many muscles are controlled by this group of nerve centres, which is comprehensive. These nerve fibres come from the middle and posterior part of the brain, through the oculo-motor, facial, glosso-pharyngeal and vagus. There is another portion of the fibres coming from the spinal cord which can be traced as far as the fourth lumbar; while a third part has been traced to the sacral part of the cord and conveyed in the pelvic nerve to modify the colon, bladder and genitals. This system of nerves is really antagonistic to the cerebral and reflex, as proved by the application of different drugs. The cranial and sacral involuntary nerves have their terminal ends stimulated by pilocarpine and paralysed by atropine, while the sympathetic system is not affected by either of these. On the other hand, adrenalin and cocaine act violently on the sympathetic system as stimulants, and codeia as a paralyser. We have another difficulty in prescribing for a particular organ when it is supplied with nerves from two systems, such as the vegetative and sympathetic—ex. gratia, the blood vessels, which we have seen are contracted by pilocarpine and distended by cocaine and adrenalin. The antagonism that exists in other secretions of an abstruse character can only be conjectured in the pancreas and suprarenal bodies, the thyroid and ovaries, or the glycogenic function of liver, which so alter and modify metabolism that disappointment is often the result of many of our efforts.

Specialisation.

At the Congress for Internal Medicine, Prof. Müller dilated largely on the abuses of this partial education in medicine. This is one of the great blemishes in the profession which called louder for a fundamental clinician. If the specialist is only a specialist he is of little worth in internal medicine. A good practitioner can always make a good specialist, but a specialist, no matter his merit, will never make a good clinician. Pathology is the handmaid to medicine, and has always been, the fundamental principle in Austrian medicine, just as physiology has been the dominant factor in German medicine. More recently chemicals and physic have been added as scientific tests in confirming many of the hypotheses abstracted from the other two fundamental principles.

Laryngo-Rhinology.

The International Congress opened this week with a history of the subject by the President. The first history he had of carrying light into any of the orifices of the body, particularly the throat, was in 1854, when Manuel Garcia, a famous music master in London, constructed a mirror for examining the vocal cords. In 1858 Ludwig Turck commenced to use a similar instrument in the examination of morbid conditions of the throat. Czermak, of Budapest, commenced shortly afterwards with artificial light, though Turck remained firm in the belief of sunlight, by means of which all his classic work has been done. Bruns, in 1862, was the first to remove a polypus, while Schrötter, in 1874, introduced the cocaine anæsthetic. Since then Störk and Schnitzler have developed this special subject into what it has now become.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Late Miss Spencer, Edinburgh Royal Infirmary.—The death is announced of Miss Spencer, who last year resigned the post of Lady Superintendent in the Infirmary. Miss Spencer was of Irish birth, and, after being trained at St. Thomas's Hospital, came to Edinburgh in 1877 as Assistant Superintendent, and ten years later succeeded to the post of Superintendent. The managers of the Infirmary recognised her thirty years of arduous service by presenting her with a service of plate, and adopted a minute expressing their appreciation of the "unwearied, devoted, and whole-hearted attention" she gave to her duties. Miss Spencer's character was one that commanded respect as well as regard; she was reticent and dignified under all circumstances, and was greatly esteemed by those who, through their intimate knowledge of her, were best able to form a judgment.

Leith Hospital.—The directors of Leith Hospital have unanimously appointed Mr. Henry Wade, F.R.C.S.E., to the post of Assistant-Surgeon to the institution rendered vacant by the resignation of Mr. Charles Heron Watson, F.R.C.S.E.

Belvedere Fever Hospital.—At a meeting of the Glasgow Council, a series of questions involving serious allegations against this hospital were put by one of the Town Councillors. He asked whether it was the case that a nurse died of enteric, after having been kept on duty for a week or ten days, during which she was complaining of feeling ill, and whether, as a protest, the other nurses refused to attend the funeral; whether there had been overcrowding to the extent of 50 patients being in a ward adapted for 15; whether there had been understaffing, and whether the Medical Superintendent had been refused more nurses. The Convener of the Public Health Committee asked that the answers might be delayed. Belvedere Hospital is under the same general management as Ruchill, in which the recent inquiry showed that overcrowding and understaffing to a scandalous extent had existed during the past year.

Medical Officer of Health for Edinburgh.—It has been agreed, subject to the approval of the Town Council, to disjoin the offices of Medical Officer of Health and Police Surgeon. The Medical Officer of Health, who will give his whole time to the work, is to receive a salary of not less than £800 per annum. As regards the Police Surgeonship, it is proposed to appoint a casualty surgeon and several divisional police surgeons at about £75 per annum.

Larbert Asylum Superintendentship.—A short list of three has been made from the eleven applicants for the post at present held by Dr. Robertson, who goes to take up duty at Morningside in June. The election will take place on May 7th, when one of the following three gentlemen will be appointed:—Dr. Campbell, Inverness District Asylum; Dr. Rutherford, Edinburgh Royal Asylum; and Dr. Sturrock, Midlothian and Peebles District Asylum.

Isolation of Phthisis at Bangour Asylum.—Dr. Keay, the Superintendent, having reported to the Parish Council that it is desirable to provide specially for the phthisical insane under his care, the Edinburgh District Lunacy Board have decided to obtain plans with the view of erecting a small sanatorium and isolation block for 20 patients in the Bangour Village Asylum.

Edinburgh Medical Officership.—The duties of the casualty surgeon, one of the offices which results from the partition of the work hitherto carried on by the Medical Officer of Health single-handed, has been defined by the Public Health and Lord Provost's Committees. It is recommended that the post be held at a salary of £100 a year by the occupant of the Chair of

Medical Jurisprudence in the University. The duties of the casualty surgeon will be to examine candidates for admission to the police and fire brigade, to pass medical certificates granted in cases of proposed retirement under the superannuation scheme, and to give his services in connection with claims made against the Corporation in respect of injuries received.

LETTERS TO THE EDITOR.

THE REFERENDUM OF THE COUNCIL OF THE BRITISH MEDICAL ASSOCIATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am afraid that your correspondent's zeal for his cause outruns his discretion, and that he shows his hand too plainly to be a good diplomatist. "Festina Lente" alleges that I have confused the Referendum with the Draft Charter, implying that I do not know the difference between the two, and then he proceeds to castigate me for "this absurd misunderstanding." I regret to disagree with him. I maintain that the Referendum, although a hostile document promulgated by the Council, is yet a most valuable *précis* of the Draft Charter: it places before the members the vital points at issue; it reminds the members of what the framers of the Draft Charter have done in the effort to introduce reforms; and it illustrates forcibly the opposition with which the majority of the Council have met the new proposals. Again, I maintain that its rejection has "marked a new era in the history of the Association," for had it been approved by the branches the Draft Charter would have been condemned in its most vital clauses, which would have implied a vote of non-confidence in the framers. Your correspondent affirms that, in his opinion, "the voting has not been on the merits of the Charter at all, but a trial of strength between two parties, the smaller of which has been defeated." I conceive that in speaking of a trial of strength, it would merely have been just to have made some reference to the strong minority on the Council who disapproved of the Referendum. It is quite possible that the report of this minority, issued with the Referendum, had a great deal to do with the result of the voting. Had the Council been unanimous upon the Referendum question, their appeal to the branches might have terminated differently, but being opposed by a strong minority among themselves, the inference is obvious that some members even of the Council concede the necessity for the reforms upon which the Referendum so conveniently sought the suffrages of the Association. Your correspondent, however, is too timorous, too imaginative, too much wedded to the past to be able to discuss this question with an open mind. He sees "danger," "imminent danger" in these schemes of reform; and, as he tells us, "every instinct of prudence and caution rises up against the proposal to turn the Association into a medical trades union and a political faction." But I fail to grasp the reasons for this fear, this misgiving, respecting the future of the Association, should these objects be ultimately attained. No one has ever seen the Falls of Niagara without regretting the display of so much natural force unconverted into a profitable use. And the same regret may be applied to the Association. The British Medical Association, in membership, is the most powerful medical body in the world, and yet its political power in the present day is absolutely *nil*. It needs but little reflection, therefore, to understand, under those circumstances, how much is lost, in a political sense, to the medical profession in Great Britain and the Colonies. The object of the Draft Charter is to amend this anomalous state of things, and thus the time should come when the Association is in a position to return a member of its body to the House of Commons, with a mandate ensuring the proper representation of the interests of the medical profession in that Legislative Assembly. Practically, every important Trades Union, and every body representing a community of interests in this country has its advocate, or advocates, in the House of Commons. On the other hand, the medical profession is the only one which has no political status. The policy, therefore, of trying to amend this anomaly is sound, is conceived in the best interests of the profession, and will do more than anything else to convince the members of the Association that much is to be gained by striving for political recognition and importance.

I am, Sir, yours truly,

NIL DESPERANDUM.

RESEARCH DEFENCE SOCIETY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A Society has been formed, with the name of the Research Defence Society, to make known the facts as to experiments on animals in this country; the immense importance to the welfare of mankind of such experiments; and the great saving of human life and health directly attributable to them.

The great advance that has been made during the last quarter of a century in our knowledge of the functions of the body, and of the causes of disease, would have been impossible without a combination of experiment and observation.

The use of antiseptics, and the modern treatment of wounds, is the direct outcome of the experiments of Pasteur and Lister. Pasteur's discovery of the microbial cause of puerperal fever has in itself enormously reduced the deaths of women in child-birth.

The nature of tuberculosis is now known, and its incidence has materially diminished.

We owe the invention of diphtheria anti-toxin entirely to experiments on animals.

The causes of plague, cholera, typhoid, Mediterranean fever, and sleeping sickness have been discovered solely by the experimental method.

Not only have a large number of drugs been placed at our disposal, but accurate knowledge has replaced the empirical use of many of those previously known.

The evidence before the Royal Commission has shown that these experiments are conducted with proper care; the small amount of pain or discomfort inflicted is insignificant compared with the great gain to knowledge and the direct advantage to humanity.

While acknowledging in general the utility of the experimental method, efforts have been made by a section of the public to throw discredit on all experiments involving the use of animals. The Research Defence Society will therefore endeavour to make it clear that medical and other scientific men who employ these methods are not less humane than the rest of their countrymen, who daily, though perhaps unconsciously, profit by them.

The Society proposes to give information to all inquirers, to publish *précis*, articles, and leaflets, to make arrangements for lectures, to send speakers, if required, to debates, and to assist all who desire to examine the arguments on behalf of experiments on animals. It hopes to establish branches in our chief cities, and thus to be in touch with all parts of the kingdom, and to be at the service of municipal bodies, hospitals and other public institutions

The Society was formed on January 27th of the present year, and already numbers more than 800 members. It is not an association of men of science or of medical men alone; its membership has been drawn from all departments of public life, and includes representatives of every class of educated Englishmen and Englishwomen, including many who have taken an active part in the prevention of cruelty to animals. This fact is in itself a remarkable protest against the attacks which have been made on the researches that the Society has been formed to defend.

The annual subscription is five shillings to cover working expenses, but larger subscriptions or donations will be gladly received. The acting Hon. Treasurer, *pro tem.*, is Mr. J. Luard Pattisson, C.B. (of the Lister Institute), and an account in the Society's name has been opened with Messrs. Coutts and Co., 440, Strand. The Hon. Secretary is Mr. Stephen Paget, 70, Harley Street, W., to whom all communications should be addressed.

I am, Sir, yours truly,

CROMER

(President).

SANITARY ADMINISTRATION.

To the Editor of The Medical Press and Circular.

Sir,—One of the periodical articles on Local Government Board reports which the *Times* systematically publishes appears in its issue of April 18th. The present article deals with the report by Dr. Reginald Farrar on the sanitary administration of a large number of small urban districts in the West Riding of Yorkshire, and another report by Dr. R. Deane Sweeting on a recent epidemic of scarlatina in the urban district of Burnham-on-Crouch (Essex). These reports tell the usual story. The members of the councils of the districts of this class "lack the public spirit and experience necessary for dealing with health problems, and are apt to be unduly biassed by local and personal considerations." In other words, the majority of members of the councils are mean, vulgar or ignorant men, unable to understand the importance of sanitary laws, or influenced by sordid personal motives, and holding their positions with the set purpose of obstructing or preventing effective administration. In such districts it is found that sanitary laws are almost entirely disregarded, or, at the best, administered in a perfunctory fashion to satisfy the bare letter of the statutes. Out of 36 urban districts in the valleys near Huddersfield, the salary paid to the Medical Officer of Health is, in 28, less than £30 per annum, and in six of these is less than £10. In none does the salary reach £50. The poverty, and not the will, of these unfortunate officials it is that compels them for such paltry hire to make themselves the servants of their ignorant masters, and to stifle their conscience in presence of the injury to the people and to the State to which, as they must see, the neglect of elementary sanitary laws gives rise. The Sanitary Inspector in these districts is often a person of very inferior education and position, sometimes a foreman road-mender or a rate-collector, paid to devote only a small part of his time to his duties, and, being devoid of the requisite technical knowledge, incompetent to make the necessary representations to his council. That this state of things should be allowed to continue is, of course, the fault of the public. They can, if they choose, turn out inferior members of local authorities and replace them by men not capable of sacrificing the welfare of the poor—it is upon the poor that the misery mostly falls—through ignorance or in pursuit of selfish aims. Unless the spirit of the people can be roused, democratic institutions will bring the nation to ruin. These institutions cannot be properly administered unless the bulk of intelligent citizens will take part, either by accepting office or helping to choose and elect representative men. In the meantime, what is our profession doing to improve its status in the service of the State? Would combination aimed at raising the salaries of medical officers and placing them in a position to carry out their duties without fear of their ignorant employers, be stigmatised as trades unionism? Is there no means of organising the profession and giving it some of the political power it ought to command? Can nothing be done to improve the present deplorable position of medical public servants, as once more disclosed in the reports to which I have referred.

I am, Sir, yours truly,

M. O. H.

April 21st, 1908.

THE IRISH UNIVERSITY BILL—PROMISES AND PERFORMANCE.

To the Editor of The Medical Press and Circular.

Sir,—Mr. Birrell, when introducing the Irish University Bill in Parliament, on March 31st, said, referring to the professorial staff of the Queen's Colleges of Cork and Galway, which it is proposed shall be constituent Colleges of the New University in Dublin:—

"The existing Professors in the Colleges of Cork and Galway will, *of course*, go on and be Professors of the new University, but upon the old terms. When they die or retire the Senate will appoint their successors."

Thus the promise. As to the performance, by the provisions of the Bill as printed after his speech, the entire staff, Presidents, Professors, and office-bearers, are summarily dismissed.

Mr. Birrell further stated that only the first appointment of Professors to the new College in Dublin was to be made by a Commission consisting of three members nominated by the Crown and four appointed by the temporary Senate of the new University.

By the Bill, however, the Commissioners are to appoint all officers of the constituted Colleges, including Presidents and Professors of Cork and Galway; they are directed to offer the dismissed Presidents and Professors of those Colleges, so far as "practical and *expedient*," analogous offices in Cork and Galway respectively; and they are to give to those whom they may not deem it expedient to appoint, such compensation as they may think fit.

As the compensation is to be paid out of the revenues of the Colleges, the prospect for the unemployed does not seem brilliant, especially in Galway, which is only to receive a beggarly £1,400 a year more than its present inadequate income.

The existing Presidents and Professors hold their offices under the Royal Sign Manual during His Majesty's pleasure. I do not think that servants of the Crown have ever before been treated in so arbitrary a manner and with such a total disregard of any compensation for the loss of their positions, or adequate compensation being secured for loss of employment.

The profession is specially interested in the question, so many of the Professors being medical men. There does not seem to be any justification for the breach of the promises made to Parliament, and I for one protest against the treatment meted out to men who have faithfully and efficiently discharged the duties entrusted to them.

I am, Sir. yours truly,

M.D.

THE ORAL USE OF SERUMS.

To the Editor of The Medical Press and Circular.

Sir,—Your editorial remarks in your issue of April 15th are calculated to leave an impression that, you will allow me to say, is not justified by facts.

That impression amounts to this—that, whilst recognising that my work on the "Rôle of Normal Serum in Disease" is not based on Paton's work, you consider that I have been anticipated by him in that work.

Will you allow me, in order to avoid any possibility of misconception, to point out, without the smallest desire to detract from the value of Paton's work:—

1. That most of his observations are based on the oral administration of *immune* serum.
2. That though he has in many cases administered the plasma of various animals in a similar manner, he has never, apparently, used normal serum as such.
3. That my work, so far published, deals with the local and internal administration of *fresh normal serum*. This work is based on the undoubted power that fresh serum has, *inter alia*, of inhibiting destruction of tissue.
4. That whatever Paton's plasma is, it certainly is not fresh normal serum.

I am, Sir, yours truly,

E. C. Hort.

[We are very pleased to insert Dr. Hort's note. There was not the least intention of imputing to him any but the most honourable motives. At the same time, it certainly appeared to us that Mr. Paton was first in the field with the oral administration of normal serum in the treatment of various diseases. Doubtless Mr. Paton will come forward himself, and the matter of priority can be thrashed out between him and Dr. Hort.—Ed. Med. P. and C.]

OBITUARY.

DR. UNDERHILL, PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

It is with feelings of the deepest regret that we have to chronicle the death of Dr. C. E. Underhill, the eminent and esteemed President of the Royal College of Physicians. Dr. Underhill's health had for the past year given grave cause for anxiety, and his death, deeply as it is lamented, was not altogether unexpected. He was of English birth, and was educated at Shrewsbury, Cambridge, and Edinburgh. In 1870 he graduated, and shortly thereafter began to practise in Edinburgh. In his early days he was associated with the late Dr. Matthews Duncan, and this no doubt determined the direction of his work. Among other offices held, he was a Physician to the Royal Hospital for Sick Children, and to the Royal Maternity Hospital. Two years ago he became President of the Royal College of Physicians, and under ordinary circumstances would have occupied the chair until the ensuing winter. Dr. Underhill held a very high position in the medical profession of the city of his adoption. He succeeded early to a large and very responsible practice on the removal of Dr. Matthews Duncan to London, and this practice he held up to almost the day of his death. It was characteristic of him that he shirked neither the cares of practice nor the onerous duties of his Presidentship, though the state of his health would have more than justified his doing so, and delegating part of his work. Dr. Underhill, however, was well fitted to be the head of the medical profession in Edinburgh by character as well as by professional eminence. He was a high-minded gentleman whose opinion was constantly being sought and treasured on many points of ethics and conduct. His advice was always freely given, and in such a form that the most sensitive could not take offence. He was impartial, sincere, and upright. Little wonder, then, that his death makes a gap for which it will be hard to find an occupant.

EDITH PECHEY PHIPSON, M.D.BERN, L.R.C.P.I.

WE regret to announce the death of Dr. Edith Pechey Phipson, one of the ablest of medical women. Mary Edith Pechey was the daughter of a Baptist minister, and was born at Langham, near Colchester, in 1846. After completing her school education, she devoted herself to teaching for a few years, but when the question of medical study for women was raised, she joined those who applied to the University of Edinburgh in 1869, and was one of the first five to matriculate in October of that year. In 1877 Miss Pechey took a diploma from the Irish College of Physicians, which led the way to the admission of women to the medical profession, and also obtained the M.D. of the University of Bern, as no English University would at that time give a degree to women. For a few years she practised medicine in Leeds, but on the foundation of the Kama Hospital for Women in Bombay in 1882 she was appointed Senior Physician to it, and did splendid service in organising its very extensive work, and to a great extent revolutionising the whole standard of hospital nursing in India.

PROFESSOR LEOPOLD VON SCHROTTER.

PROFESSOR LEOPOLD SCHRÖTTER VON KRISTELLI, of the Vienna medical faculty, died suddenly on Tuesday night, April 21st, in the 71st year of his age. As President of the Congress of Laryngologists he recently delivered an inaugural address. The delegates to the Congress were painfully surprised by the news of his sudden death, although, at the request of his family, the Congress did not adjourn. He was best known to the public as the leader of the movement for the prevention of tuberculosis and as the founder of the Alland Sanatorium near Vienna. His influence also aided the development of Abbazia and the Austrian Riviera as a health resort.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:—

SIDNEY APPLETON (London).

Diseases of the Nervous System. Edited by A. Church, M.D., and Julius L. Salinger, M.D. Illustrated. Pp. 1905.

Anatomy of the Brain and Spinal Cord. By Harris E. Santee, M.D., Ph.D. Fourth Edition. Revised and Enlarged. Illustrated. Pp. 453. Price 12s. 6d. net.

Medical Gynæcology. By Howard A. Kelly, A.B., M.D., LL.D., F.R.C.S. Illustrated. Pp. 662. Price 25s. net.

EDWARD ARNOLD (London).

Movable Kidney; Its Pathology, Symptoms and Treatment. By Harold W. Wilson, M.B., B.S.Lond., F.R.C.S.Eng., and C. M. Hinds Howell, M.A., M.B., B.Ch.Oxon., M.R.C.P. Lond. Illustrated. Pp. 104. Price 4s. 6d. net.

The Influence of Alcohol and Other Drugs on Fatigue. By W. H. R. Rivers, M.D., F.R.C.P. Pp. 136. Price 6s. net.

BAILLIERE, TINDALL AND COX (London).

A Text-Book of Pathology. By Francis Delafield, M.D., LL.D., and T. Mitchell Prudden, M.D., LL.D. Eighth Edition. Illustrated. Pp. 650. Price 25s. net

Meat and Food Inspection. By William Robertson, M.D.Glas., D.P.H. Illustrated. Pp. 372. Price 10s. 6d. net.

The Diagnosis and Treatment of Pulmonary Tuberculosis. By Francis M. Pottenger, A.M., M.D., Illustrated. Pp. 377.

Clinical Lectures on the Surgical Diseases of the Urinary Organs. By P. J. Freyer, M.A., M.D., M.Ch. Illustrated. Pp. 425. Price 12s. 6d. net.

Aids to Ophthalmology. By N. Bishop Harman, M.A., M.B., F.R.C.S. Fourth Edition. Illustrated. Pp. 165. Price, cloth 2s. 6d. net, paper 2s. net.

The Pocket Osteology. By Philip Turner, B.Sc., M.B., M.S., F.R.C.S. Pp. 187. Price 3s. net.

ADAM AND CHARLES BLACK (London).

Cancer: Relief of Pain and Possible Cure. By Skene Keith, M.B., F.R.C.S.Ed., and George E. Keith, M.B., C.M. Pp. 155.

Home Nursing and Hygiene. By Florence Hufton-Windust. Pp. 122. Price 1s. net.

CASSELL AND CO., LTD. (London).

The Romance of Medicine. By Ronald Campbell Macfie, M.A.Aberd., M.B., C.M. Illustrated. Pp. 312. Price 6s.

CHURCHILL J. AND A. (London).

Hernia: Its Cause and Treatment. By R. W. Murray, F.R.C.S. Pp. 99. Price 4s. 6d. net.

EDWARD EVERARD (Bristol).

A Chronology of Medical History. By James Young, M.D.

HENRY FROWDE (London).

The Quarterly Journal of Medicine. Edited by William Osler, etc., etc. Vol. I., No. 3. April, 1908. Price 8s. 6d. net.

HENRY FROWDE AND HODDER AND STOUGHTON (London).

Diets in Tuberculosis: Principles and Economics. By Noel Dean Bardswell, M.D., M.R.C.P., F.R.S.Edin. and John Ellis Chapman, M.R.C.S., L.R.C.P. Pp. 184. Price 6s. net.

CHARLES GRIFFIN AND CO., LTD. (London).

Infancy and Infant-Rearing: An Introductory Manual. By J. B. Hellier, M.D.Lond., M.R.C.S.Eng. Illustrated. Second Edition. Revised. Pp. 164. Price 3s. 6d.

Tropical Medicine, Hygiene and Parasitology: A Handbook for Practitioners and Students. By Gilbert E. Brooke, M.A. Cantab., L.R.C.P.Ed., D.P.H. Illustrated. Pp. 498.

JOHN HOGG (London).

Knaves or Fools? By Charles E. Wheeler, M.D., B.S., B.Sc.

H. K. LEWIS (London).

An Essay upon Disease: Its Cause and Prevention. By G. E. Richmond, M.D.Lond. Pp. 96. Price 2s. net.

J. B. LIPPINCOTT AND CO. (London).

Treatment of Internal Diseases: For Physicians and Students. By Dr. Norbert Ortner. Edited by N. B. Potter, M.D. Translated by F. H. Bartlett, M.D. Pp. 658. Price 21s. net.

Text-Book of Ophthalmology. By Dr. Ernst Fuchs, of Vienna. Translated by Alexander Duane, M.D., of New York. Third Edition. Price 25s. net. 1908.

LONGMANS, GREEN AND CO. (London).

Proceedings of the Royal Society of Medicine. Vol. I., Nos. 4 and 5. February and March, 1908. Price 7s. 6d. net each.

A Mind that Found Itself. By Clifford Whittingham Beers. Pp. 363. Price 7s. 6d. net.

MACMILLAN AND CO., LTD. (London).

A Treatise on Chemistry. By H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S. Vol. II. The Metals. New Edition. Pp. 1436. Price 30s. net.

METHUEN AND CO. (London).

Diseases of Occupation from the Legislative, Social and Medical Points of View. By Thomas Oliver, M.D., F.R.C.P. Pp. 427. Price 10s. 6d. net.

NEW SYDENHAM SOCIETY (London).

Atlas of Clinical Medicine, Surgery and Pathology. Fasciculus XXV. Diseases of Fallopian Tube, Ovary, Uterus, etc

NISBET, JAMES AND CO., LTD. (London).

Injuries of Nerves and Their Treatment. By James Sherren, F.R.C.S.Eng. Pp. 310. Price 5s. net.

OAK PRINTING COMPANY (Chicago).

The Correction of Featural Imperfections. By Charles C. Miller, M.D. Second Edition. Enlarged. Pp. 136.

HENRY RENSHAW (London).

A Manual of the Practice and Theory of Medicine. By Sir Wm. Whitla, M.A., M.D., LL.D. 2 vols. Pp. 1900.

W. B. SAUNDERS CO. (Philadelphia).

Nothnagel's Practice of Medicine: Diseases of the Heart. Edited, with additions, by George Dock, M.D. Illustrated. Pp. 1,000. Price 21s. net.

Surgery: Its Principles and Practice. Vol. III. Edited by W. W. Keen, M.D., LL.D. Illustrated. Pp. 950. Price 30s.

Atlas and Text-Book of Human Anatomy. Vol. III. By J. Sobotta, M.D. Edited by J. Playfair McMurrich, A.M., Ph.D. Illustrated. Pp. 250. Price 25s. net.

A Text-Book of Surgical Anatomy. By W. F. Campbell, M.D. Illustrated. Pp. 500. Price 21s. net.

SMITH, ELDER AND CO. (London).

Saint Bartholomew's Hospital Reports, Edited by H. Morley Fletcher, M.D., and W. McAdam Eccles, M.S., F.R.C.S.

JOHN WRIGHT AND CO. (Bristol).

The Medical Annual: A Year-Book of Treatment and Practitioners' Index. 1908. 26th year. Pp. 883. Price 8s. 6d. net.

Supplementary First Aid to Miners. By William B. Arthur, L.R.C.P., L.R.C.S.Ed. Pp. 27. Price 6d. net.

On the Best Method of Sewage Disposal for all Communities. By F. Wallis Stoddart. Third Edition. 1908. Illustrated.

WEEKLY SUMMARY OF MEDICAL LITERATURE, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

Interstitial Keratitis after the Use of Calmette's Ophthalmo-Reaction.—Dr. Arnold Knapp (*Arch. of Ophthalmology*, March 1908), comments on the absence of unfavourable symptoms arising during the application of the above test. Kalt, at the Paris Ophthalmological Society, in October and November, 1907, recorded a case in which severe symptoms set in after the use of a 1 per cent. tuberculin solution, and lasted one month, with reduction of vision. He considered the presence of tuberculous internal eye trouble a contraindication to the use of the test. Knapp records a case of typical tuberculous interstitial keratitis which followed the instillation of tuberculin. The principal points about the case were the following:—A healthy girl, æt. 9, came to hospital on account of a scrofulous superficial keratitis of the right eye of two months' duration. The right cornea presented a central, broken-down, superficial infiltration. Marked photophobia. But little progress followed the usual treatment in hospital. An ulcer which formed on lid margin also proved very resistant to treatment. On December 14th one drop of a 1 per cent. tuberculin solution was put into the left eye, which was quite healthy. In six hours the lids were very red and swollen and there was great pain. For two days the condition remained about the same, viz., the lids could be separated with difficulty, thin muco-fibrinous, microbe free discharge. Temperature rose to 100.4° F. In ten days infiltrations appeared round the temporal margin of the cornea. They were in the superficial layers of the true cornea and the overlying epithelium was elevated. On January 28th the infiltrations had coalesced, forming three yellowish-grey patches, 2 to 3 m.m. in diameter, with deep-seated corneal vessels running to them. This unfortunate case demonstrates that the ophthalmo-raction cannot be regarded as harmless. M.

Varicose Ulcers of the Leg.—E. Adams, in a paper (*Post Graduate*, March, 1908) on this common affection, discusses various forms of treatment, and in particular the operations of Trendelenberg and Schede. The former, which consists in removing a portion of the internal saphenous vein, should, in the author's opinion, only be done when the valves of the saphenous vein have been demonstrated to be insufficient. This can be done in the following way:—The patient is put lying down, the leg raised and emptied of blood; after several minutes compress the internal saphenous vein about the lower third of the thigh, by means of a bandage, then lower the leg and let the patient stand up; if the blood flows into the saphenous vein from above and distends that portion of the vessel above the bandage, the valves are incompetent, and the operation should be performed. Schede's operation consists of a circular incision at the upper and middle third of the leg, encircling the limb, and the removal of all the veins to the deep fascia. Adams draws the following conclusions:—1. Varicose ulcers are very stubborn to treatment; the best results have been obtained by the use of sponge grafts, combined with Unna's bandage. 2. Radical operations on varicose veins are necessary to ensure a permanent cure. 3. Trendelenburg's operation in combination with Schede's gives the best results. G.

Retention of Urine in Adolescents.—V. Blum (*Wien. Rundschau*, October, 1907) reports the case of a boy, æt. 13, who at the age of 7 had fractured his frontal bone and had severe concussion. At 11½ hæmaturia appeared, and subsequently both nocturnal and diurnal incontinence of urine. The boy's genital organs were small and poorly developed, the prostate being rudimentary; the bladder was distended, reaching above the umbilicus. The urine was clear and free from albumin; the knee-jerks were greatly exaggerated. The urine was slowly drawn off by catheter, but temperature rose to 104°, and the patient became rapidly worse, dying the following day. A post-mortem examination showed an acute hæmorrhagic pyelonephritis in both kidneys, with dilated ureters; it also demonstrated the fact that there was no stricture, valve or any abnormality in the urethra which could possibly have caused a mechanical obstruction to the outflow of urine. In the absence of obstruction to the passage of urine, the retention was primarily attributed to the poliomyelitis, which was found in the cord at the level at which the centre for micturition is generally supposed to be. This case seems to prove beyond doubt the existence of a vesical centre in the spinal cord. G.

Tumours of the Urinary Bladder.—Von Frisch reports (*Wien. Klin. Woch.*, No. 40) shortly on 300 cases of bladder tumour. Most of the patients were elderly; 256 were men, the remaining 44 were women. About two-thirds of all the cases proved on microscopic examination to be malignant. In all the cases the growths were explored, and, if possible, removed, by a supra-pubic incision; in one case only was a tumour removed by the vesico-vaginal route; 42 of the patients died from the operation, or an average mortality of 14 per cent. The average time in healing after operation was 25 days. In 164 of the cases it was possible to trace the after-histories for periods varying from one to seventeen years. Of these there were 53 apparently benign papillomata, with 21 recurrences; 49 epitheliomas, with 29 recurrences; and 62 carcinomatous tumours, all of which had recurred. The operative prognosis of carcinoma seems almost hopeless as regards cure, but in many cases life was prolonged and in others suffering much alleviated. G.

Tertiary Syphilis.—L. Bonnet (*Lyon Médical*, November, 1907) describes the case of a man, æt. 79, with two ulcers on his right forearm. He contracted syphilis at the age of 24, and was treated with mercury for one month. He was entirely free from any symptoms of syphilis for 54 years, until the two sores appeared on his arm. These were typical gummata, and healed up in 12 days on the administration of K.I. in large doses. The frequency with which tertiary lesions occur seems, to a great extent to depend on the insufficiency of the early administration of mercury, and the mildness of the secondary symptoms; but it is very rare indeed for such a long period as 54 years to elapse between the primary and tertiary manifestations. Out of 4,400 cases recorded by Fournier, in only three cases did the history extend over 50 years. G.

Dangers of Lumbar Puncture.—Prof. Wolff (*Berlin. Klin. Woch.*, November) attempted to perform an operation on the knee of a man, æt. 36, under spinal anæsthesia. The needle was inserted without any trouble between the third and fourth lumbar vertebræ. No cerebro-spinal fluid came away after the canal had been entered, but there was a free escape of pure blood. The needle was at once withdrawn without attempting to make a spinal injection, and the operation was carried out under a general anæsthetic. A few hours later severe pain came on in the patient's back. The pain was spasmodic in character, and extended to the front of the chest and the shoulders. The next day there was severe pain in the neck, and later on in the head itself, these pains lasting for about a week. Five days after the operation the sixth nerve on the right side suddenly became paralysed; this only passed off after three weeks. The hæmorrhage on the introduction of the needle was evidently due to the puncture of an intra-dural vessel. G.

Remarks on the Treatment of Fractures of the Patella of Long Standing.—Lord Lister (*Brit. Med. Journ.*, April 11th, 1908) describes a method he used when there was considerable separation of the fragments of the patella, instead of employing free division of quadriceps extensor muscle to approximate the fragments. The operation is done in two stages. In the first stage an incision is made over each fragment. A wire is passed through the upper fragment, and the long ends of this wire are pulled through under the skin to the lower incision, where the one end is passed through the lower fragment. The upper fragment is then pulled down as much as possible by a very strong sharp hook, the point of which is inserted in the tendon of the quadriceps at its attachment. The wire is secured in the usual way, and then is cut short. The limb is put up in an elevated position with the knee extended to relax the quadriceps. The limb is gradually lowered in the course of a few days. When the wounds are healed, the treatment can be completed. The patella is cut down on, the broken edges of the patella freshened, and the quadriceps will be found sufficiently extended to allow the fragments to be wired in apposition with one another, with resulting good bony union. S.

Remarks on Treatment of Four Hundred Cases of Epithelioma.—Bulkley and Janeway (*Med. Record*, March 21st, 1908) point out that routine treatment of every lesion diagnosed as epithelioma, whether it be by excision, caustics, X-rays, or other means, is to be deplored, as each case should be a special study from the beginning until a perfect cicatrix results. They emphasise the following facts:—Epithelioma runs a relatively benign course. It occurs chiefly about the face, in places where radical operative measures are apt to produce serious deformities, which very materially add to the patient's discomfort. Their experiences of 35 years demonstrate that, while many cases can be permanently cured by caustic pastes, these are at times disappointing, and may lead to an aggravation of the trouble. The curette cannot be depended on alone, but requires additional destructive agents to the base left after operation. By the proper use of X-rays we have a safe and—in cases that have not been grossly neglected or maltreated—a sure method of cure, with the least amount of deformity. In cases where knowledge and experience show that these measures are not likely to avail in checking the course of the disease, complete surgical removal should be undertaken, as this has been shown to be permanently successful in a reasonable proportion of cases. S.

Arthrodesis and Tendon Transplantation.—Jones (*Brit. Med. Journ.*, March 28th, 1908) in discussing arthrodesis (of the ankle especially), is strongly of opinion that it should not be performed on children under 8 years of age, nor until the surgeon is satisfied that the muscles are paralysed beyond hope of recovery. The preliminary preparation of the foot by wrenching and the tenotome must correct all deformities. The operation should be so planned that at its completion the bones lie in apposition to the foot, which should be placed in an over-corrected position. This is effected by the ex-section of skin flaps, by the shortening of lengthened tendons, and by the removal of graduated wedges of bone. The wedge should never be taken from the tibia, lest the tibial epiphysis be injured. Splints should be applied and retained until union is pronounced to be complete, and appliances should be worn until the surgeon has evidence that the ankle can bear body weight without fear of yielding. In the author's opinion the indications for tendon transplantation are:—(*a*) To fortify a weakened group of muscles; (*b*) to supplant a completely paralysed muscle or group of muscles; (*c*) to obstruct an over-acting spastic group; (*d*) to deviate tendon action when perverted, as in transference of the tendo-Achillis to the outer side of the os calcis in congenital club-foot to prevent inversion of the ankle; (*e*) as a help in partial arthrodesis. It is important to remember that a muscle, if stretched for a sufficiently long period, will cease to act; also that an over-stretched muscle will regain its power if relieved from strain. The causes of failure in tendon transplantation may be thus summarised:—(*a*) Inadequate tension of the reinforced muscle; (*b*) inadequate preliminary correction of deformity; (*c*) early adhesions of transplanted tendons; (*d*) insufficient freeing of the tendon; (*e*) over-deflection of the transplanted tendon; (*f*) over-strain upon the transplanted tendon. In tendon transplantation the author insists on:—(1) The over-correction of deformity as a preliminary act; (2) the removal of skin flaps to secure the uninterrupted continuity of the over-correction; (3) the direct and not angular deflection of the tendon, with free tunnelling in one plane through the soft tissues; (4) the firm suturing into periosteum or bony groove; (5) the careful choice, tension, and nursing of the transplanted tendon; (6) the maintenance of a hyper-corrected position until voluntary power is assured to the tendon; (7) the deflection of the body weight during walking from the reinforced tendon. It is also often well to shorten all the paralysed tendons, and prevent the over-action of their opponents by tenotomy. In all the author's cases of arthrodesis and tendon transplantation, he employs the tourniquet, and insists upon scrupulous asepsis. All hospital cases are treated as out-patients and return to their homes on the day of operation. No difficulty arises from this arrangement. S.

MEDICAL NEWS IN BRIEF

Meeting and Exhibition of the Electro-Therapeutic Section of the Royal Society of Medicine.

The first monthly meeting of the section held in Scotland will be in the rooms of the Royal Philosophical Society, Bath Street, Glasgow, on Friday, 22nd May, at 8.30 p.m. Mr. Wm. Deane Butcher, M.R.C.S., President of the Section, will occupy the chair, when the following papers will be read:—Dr. H. Lewis Jones, Medical Officer in charge of the Electrical Department, St. Bartholomew's Hospital, London, "Interrupted Currents for Electrical Testing and Treatment"; Dr. Dawson Turner, Medical Officer in charge of the Electrical Department, Royal Infirmary, Edinburgh, "Some Reflections Based upon the Work done in the Electrical Department of the Royal Infirmary, Edinburgh"; Dr. Samuel Sloan, a Vice-President of the Section and Chairman of the Scottish Committee, "Ionic Medication in the Treatment of Some Obstinate Cases of Pelvic Disease in Women." An exhibition of electrical apparatus will be held in the same place, from 3 p.m. till 10.30 p.m. of the same day. Light refreshments will be provided free of cost to visitors. The meeting and exhibition will be open to all duly qualified medical practitioners. As the attendance in the evening will probably be considerable, it is requested that those who may find it convenient to visit the Exhibition in the afternoon will do so.

The Tsetse Fly.—Dr. Koch's Proposals Opposed.

The Berlin Association for the Preservation of Game in Africa recently protested against the proposal of Professor Koch to shoot down all big game in the African Colonies in order to exterminate the tsetse fly. Professor Matschie, of the Royal Zoological Museum, said that, according to Professor Koch, the tsetse fly was formerly prevalent over the whole of South Africa, but had disappeared in districts where gregarious game, such as the buffalo and the antelope, had ceased to exist. This claim, he added, could be only conditionally admitted. In the first place, it had not been proved that the tsetse fly was once distributed over the whole of South Africa, and in the second place there were many districts where big game had been exterminated and where the tsetse fly was still found in large numbers. Professor Koch, he continued, might be right as regards the Transvaal and the Limpopo districts, for the tsetse fly, which was once prevalent there, had now disappeared, but it seemed equally probable that this disappearance might be due to the clearance of the bush and undergrowth. Dr. Sander, of the Army Medical Corps, also pointed out that the tsetse fly needed much shade and preferred low dense undergrowth, and he contended that the pig, the donkey, the zebra, the wild cat, the dog, and other small animals were equally with big game intermediaries for the spread of the tsetse fly. The opinions expressed at the meeting are to be forwarded to the Colonial Office. —*Morning Post.*

Infants' Health Exhibition.

The Incorporated Institute of Hygiene, of Devonshire Street, W., is promoting an infants' health exhibition, which will be opened on June 15th, and will show the latest improvements connected with foods, clothing, the nursery, the bedroom, recreation, physical exercise, school life and education. The exhibition will appeal strongly to mothers, heads of families, members of the medical profession, matrons, nurses, and school teachers.

Army Medical Service.

An examination of candidates for not fewer than thirty commissions in the Royal Army Medical Corps will be held on July 29th and following days. Applications to compete should be made to the Secretary, War Office, London, S.W., not later than July 20th, on which date the list will be closed.

The Army Council has decided that medical officers shall practice in peace time military requirements based on definite instructions so as to ensure smooth working of the Medical Services in war time.

Hospital for Sick Children.

An earnest appeal to the public for support of the specially deserving charity the Hospital for Sick Children, Great Ormond Street, is being made through the London Press. It is pointed out that Her Majesty the Queen, who has for many years taken great interest in the hospital, has graciously consented to open in June the new out-patient department which has recently been built by Mr. W. W. Astor as a memorial to his late daughter. The hospital was founded on a small scale by that immortal friend of children, Charles Dickens, Dr. Charles West, and a few others, fifty-six years ago, and was the first hospital ever established in this country for children. It has been well called "the mother of children's hospitals," and has been the model for all other similar institutions. It is not, however, merely the oldest, but it is also now the largest children's hospital in the British Empire. It treats children from all parts of the country, and students from every quarter of the world frequent its wards to study children's diseases. Unfortunately the hospital is burdened with a debt of £15,000, and the assured annual income falls short of the necessary annual expenditure by £5,000, while the new out-patient department, by adding immensely to the efficiency of the hospital, will increase this deficit by £1,000 a year. Contributions should be sent to the Secretary, Mr. Stewart Johnson, at the Hospital, Great Ormond Street, London.

Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this society, held on the 15th inst., Dr. de Havilland-Hall in the chair, it was reported that the amount of sickness pay disbursed by the society in the first three months of this year had been somewhat augmented by the epidemic of influenza, but the number of claims from this source now being received is not great, and the illnesses are for the most part of short duration. The number of new members obtained this year is larger than in any previous similar period and has so far beaten the record figures of last year. The annual report, to be presented to the members on May 21st, will show that during the year 1907 the society has largely grown, both in members and in financial strength.

PASS LISTS.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 16th inst., with the following results:—

First Examination, Four Years' Course.—Mr. Thomas Gray.

First Examination, Five Years' Course.—Of 33 candidates entered the following 16 passed:—Stanley D. Large, Ibrahim Ladhabhai Asrani, William F. Gibb, James Remers, William C. Davis, Percy W. Laidler, John M. Milne, Donald S. Graham, Bhaskar Mahadev Tembe, Devarayadoorg Venkata Giri, Arthur Butterfield (with distinction in Chemistry), William W. W. Watt, Edgar Annequin (with distinction in Chemistry), John N. Clark (with distinction in Chemistry), Clement M. Bradley, and Matthew McL. Bainbridge; and 1 passed in Physics, 4 in Biology, and 5 in Chemistry.

Second Examination, Five Years' Course.—Of 20 candidates entered the following 9 passed: Morris Greene (with distinction), Charles L. Ievers, Robert E. N. Martyn-Clark, Patrick Walsh, Richard A. Mirzan, Gordon Beveridge, Leon Galdemar, Archibald C. Tait, and Henry G. Lamberty; and 2 passed in Physiology.

Third Examination, Five Years' Course.—Of 26 candidates entered the following 13 passed:—Sydney G. Tibbles, Robert W. A. Brown, Thomas Walsh, Walter Crosse, Daniel Murphy, Stanley W. Hogg, Ruttonbai Cooverji Nazir, Abhayabala Singha, Ethel A. Mordaunt, Isabel P. Ashley, William C. L. Malone, Richard F. Lunn, and Devarayadoorg Venkata Giri; and 1 passed in Pathology and 2 in Materia Medica.

Final Examination.—Of 47 candidates entered the following 22 passed the examination and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. and S.G.:—James H. Johnston (with honours), Alexander D. Falkner, Gajanan Jinabhai Mahimtura, David L. Luckhoo, Millicent V. Webb, Mahlon W. Locke, Thomas B. Eames, Dwarkabai Wassantrao Kamalakar, Ruttonbai Cooverjee Nazir, Charles A. Paterson, Robert W. Pickup, Vincent S. Delany, Michael J. Hayes, Harry Stokes, Edward Lewis, Leo Patchett, Krishnarao Ganpatrao Dhairyawan, Aiknath Viswanth Bam, Arthur M. Davie, Jacobus du Toit Malan, Adeline M. Watts, and John B. Cooke; and 3 passed in Medicine, 6 in Midwifery, and 4 in Medical Jurisprudence.

The Royal University of Ireland.

The following candidates passed the Second Examination in Medicine:—

Upper Pass.—Henry L. Barneville, William K. Calwell, Frederick Crooks, Samuel R. Foster, Robert J. McConnell, Laurence P. Mulligan, William Wilson.

All the above may present themselves for the further examination for Honours.

Pass.—Michael J. Black, John L. Brown, David Calwell, Patrick E. Carroll, Peter A. Clearkin, Pierce Cotter, John F. Craig, Alexander J. Dempsey, Laurence Doyle, Francis H. Duke, David J. Foley, Henry A. Gillespie, Thomas D. Graham, Harry P. Hannigan, Robert Harrington, Joseph Horan, Michael J. Horgan, B.A., Norman L. Joynt, Ignatius P. Kelly, John L. Kilbride, Jane L. Law, Homer H. C. Lynch, Patrick McCartan, Daniel J. MacClancy, Hugh J. S. McClintock, Louis J. E. McHugh, Daniel McSparron, William M. Millar, Edgar Morison, Mary A. Murphy, Daniel O'Brien, William O'Brien, Patrick J. O'Grady, Joseph Patrick, Joseph H. Porter, Adiel E. H. Reid, Thomas G. Rothwell, James J. Ryan, Samuel J. Turkington, Patrick W. White, Samuel J. Yeates.

Exempt from Further Examination in Anatomy and Physiology.—Eileen M. O'Keeffe.

Society of Apothecaries of Ireland.

At the Primary Examination, held during the present month, the following candidates passed:—Part I.—Biology.—R. B. F. Frazer, R. H. Pettersson, S. J. S. Reid. Chemistry.—R. B. F. Frazer. S. J. S. Reid. Materia Medica and Pharmacy.—E. Carter, H. R. Coombes, F. C. Eberhardt, J. McManus.

Part II.—Anatomy.—G. S. Bate, J. A. A. Boddy, C. S. Foster, E. A. S. Hoare, A. J. V. Mathews, J. G. Reidy. Physiology.—G. S. Bate, J. A. A. Boddy, J. Brearley, P. Hirschbein, E. A. S. Hoare, J. B. Holmes, J. G. Reidy, W. G. Tickell, C. B. Welsby.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3. Half Page, 13 insertions, at 35s.; 26 at 32s.; 52 at 30s. Quarter Page, 13, at 18s.; 26 at 16s.; 52 at 15s. Eighth Page, 13, at 9s.; 26 at 8s.; 52 at 7s. 6d.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

Mancas.—It is very difficult for us to award praise or blame in these cases. The difficulties of hospital administration are too well known to us. The admission of emergency cases must depend on the discretion of the house-officer, and he has to be guided by the number of beds available. There should always be beds available for accidents, of course, but at busy times it is not possible to manufacture them at a moment's notice.

Bis dat qui Cito dat.—A trip to the Canary Islands would probably meet the requirements of the case.

Aero-cult.—There is an apparatus of the same description invented by M. Bernheim, of Paris, who passes the air in buildings through several layers of amianth heated to 180 deg. Cent., and thus effects sterilisation.

THE POST OF CORONER.

The professional status of a coroner in this country has always been a matter of debate. Whether it is best that he should belong to the legal or the medical profession is still a question which has absolutely to be determined. Apparently in America the qualifications for the post of coroner are not so stringently insisted upon, as the following funny incident will show:—An inquest was being held upon a man who had been run down and killed by a motor-car. "Where was he struck?" asked the coroner of the medical witness. "At the junction of the dorsal and cervical vertebræ," was the reply. Whereupon the coroner said, "Will you please point that out on the map?" indicating with his finger a large map that hung on the wall.

Dr. B. B. F.—We cannot advise without knowing more of the circumstances of the case. So far, however, as we can judge, the matter must rest entirely upon the interpretation of the bond.

Mr. S. S. J.—The date for sending in applications has now passed, but there will be another examination held in the autumn, of which due notice will appear in our columns.

Dr. W. D. L. is thanked for his communication, which is greatly appreciated

Dr. J. Purcell.—Of the foreign health resorts, we should say, from personal knowledge, that Aix-les-Bains would be the most suitable for your patient, and June the best month.

Meetings of the Societies, Lectures, &c

Thursday, April 30th,

Royal Institution of Great Britain (Albemarle Street, Piccadilly, W.).—3 p.m.: Mr. W. Bateson: Mendelian Heredity. (Lecture I.) (Tyndall Lectures.)

Friday, May 1st.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith Road, W.).—8.30 p.m.: Prof. H. Spencer: The Advantage of Abdominal and Pelvic Examination in Pregnancy. Dr. S. Taylor: Some Neglected Remedies.

Royal Institution of Great Britain (Albemarle Street, Piccadilly, W.).—5 p.m.: Annual Meeting. 9 p.m.: Prof. J. Larmor: The Scientific Work of Lord Kelvin.

Appointments.

Askins, J., M.B., B.Ch., B.A.O.Dub., Medical Inspector of School Children by the Merthyr Tydvil (Glamorganshire) Education Committee.

Barry, J. P., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Inistioge District of the county of Kilkenny.

Casey, Charles, L.R.C.S.Irel., L.A.H.Dub., Medical Officer and Medical Officer of Health to No. 2 District of the North Dublin Union.

Dunn, Arthur Gibson, M.B., B.S.Durh., M.R.C.S., L.R.C.P. Lond., Resident Medical Officer at the Newcastle-upon-Tyne Dispensary.

Edwards, H. J., M.D.Durh., D.P.H., Certifying Surgeon under the Factory and Workshop Act for the Lynton District of the county of Devon.

Fothergill, W. E., M.D., C.M.Edin., Honorary Assistant Gynæcological Surgeon to the Manchester Royal Infirmary.

Howe, C. W., M.B., B.S.Edin., D.P.H., Certifying Surgeon under the Factory and Workshop Act for the Haddenham District of the county of Cambridge.

Kelly, M. W., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Killanne District of the county of Wexford.

Pirie, W. R., M.B., M.S.Aberd., Assistant Physician to the Aberdeen Royal Infirmary.

Roderick, Stanley James, M.B., C.M.Edin., Medical Inspector of School Children by the Llanelly (Carmarthenshire) Education Committee.

Smith, Frederick, M.B., B.S.Aberd., Assistant Anæsthetist to the Aberdeen Royal Infirmary.

Thomas, Frank Leslie, M.B., B.S.Lond., L.R.C.P.Lond., M.R.C.S., Honorary Medical Officer to the North Devon Infirmary, Barnstaple.

Wilshaw, R. H., M.B., Ch.B.Vict., D.P.H., Medical Officer of Health for the Combined Sanitary Districts of Worthing Borough and East Preston.

Vacancies.

Staffordshire County Asylum at Stafford.—Second Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and attendance. Applications to the Medical Superintendent.

King Edward VII. Sanatorium, Midhurst, Sussex.—Senior Assistant Medical Officer. Salary, £150 per annum, with board, lodging, and attendance. Applications to the Hon. Secretary, 19, Devonshire Street, Portland Place, London, W.

Lambeth Workhouse.—Assistant Medical Officer. Salary, £125 per annum, with board, apartments, and washing at Renfrew Road Workhouse. Applications to James L. Goldspink, Clerk, Guardians' Board Room and Offices, Brook Street, Kennington.

Nottingham City Asylum.—Second Assistant Medical Officer. Salary, £150 per annum, with board, apartments, etc. Applications to the Medical Superintendent.

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer. Salary, £150 per annum, with board, apartments, attendance, and washing. Applications to the Medical Superintendent.

Lincoln General Dispensary.—Resident Male Junior House Surgeon. Salary, £175 per annum, with furnished apartments, fire, and gas. Applications to the Secretary, 2, Bank Street, Lincoln.

London County Asylum, Horton, Epsom, Surrey.—Assistant Medical Officer. Salary, £150 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6, Waterloo Place, London, S.W.

Fermanagh County Asylum.—House Surgeon. Salary, £62 per annum. Applications to C. Wilson, Secretary. (See Advt.)

The Children's Hospital.—House Surgeon. Salary at the rate of 50 guineas per annum, with board, &c. Applications to Hon. Secretary, Medical Board. (See Advt.)

Births.

Brownlie.—On April 24th, at Drayton House, Redcar, wife of A. Brownlie, M.D., of a son.

Hubert.—On April 23rd,, at Rosehill, Billingshurst, Sussex, the wife of W. A. Hubert, M.R.C.S. Eng., L.R.C.P., Lond., of a son.

Marriages.

Forsyth—Livermore.—On April 22nd, at the Parish Church, Neston, Cheshire, Charles Forsyth, F.R.C.S. Ed., and J.P. of Hong-Kong, second son of Charles Forsyth, Esq., of Berwick-on-Tweed, to Dorothy Mary, daughter of Mr. and Mrs. Martin Livermore, of Turzum, Neston.

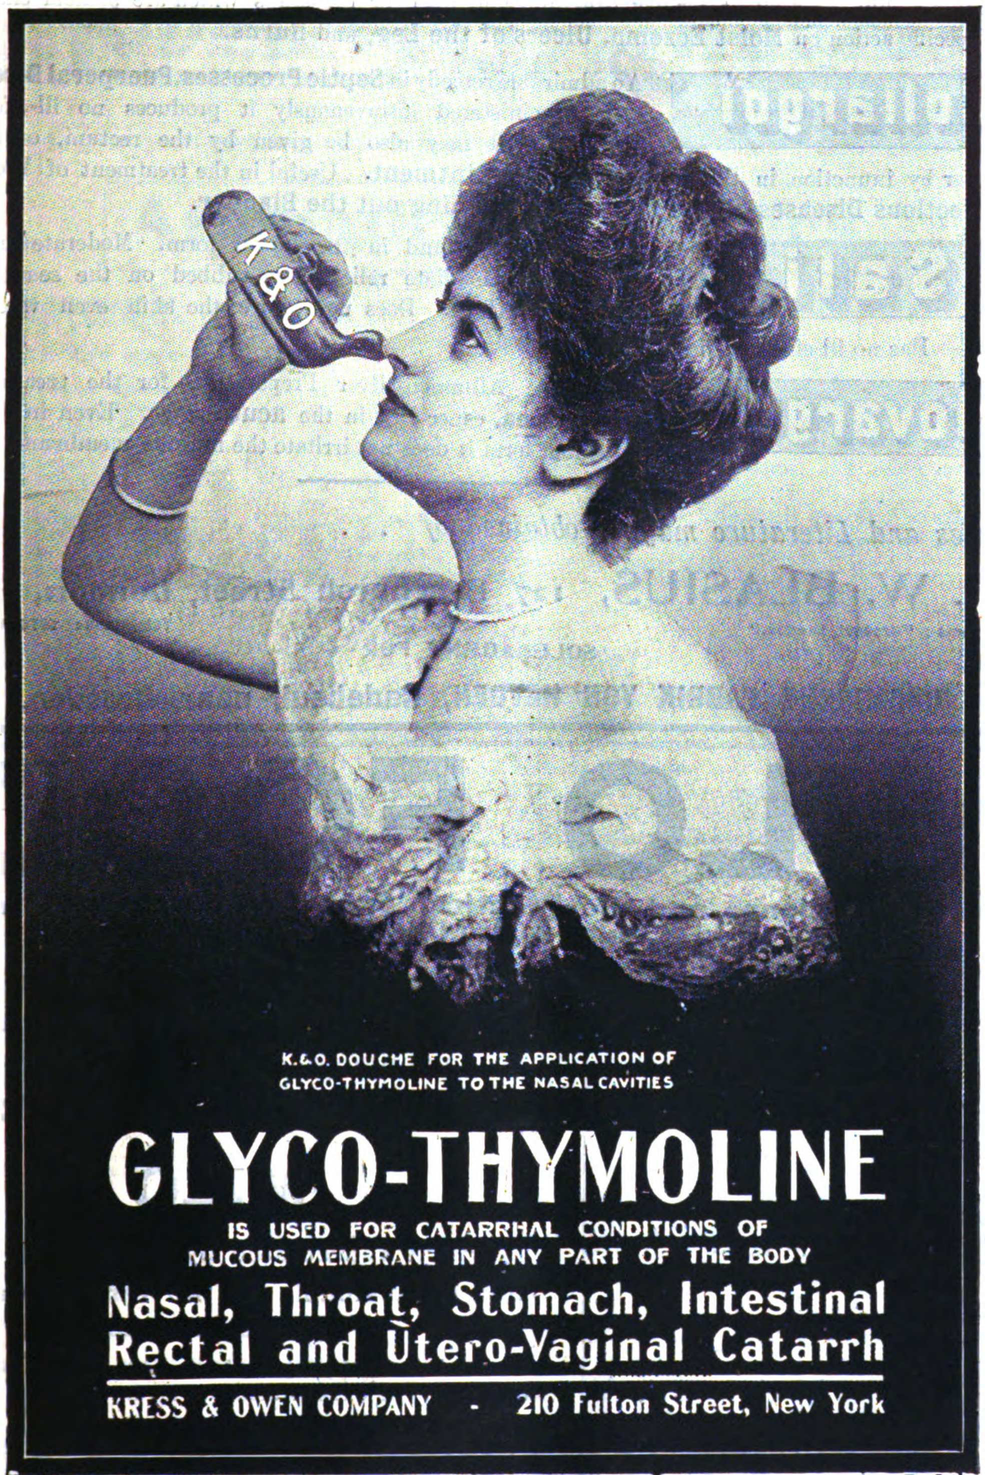
Gibson—Palmer.—On April 23rd, at Holy Trinity Church, Redhill, Robert Esplin Gibson, eldest son of David Gibson, of Demerara and Redhill, to Gwendoline, fourth daughter of the late Montague Palmer, Esq., M.R.C.S., L.R.C.P.Lond., F.S.A.

Deaths.

Carden-Noad.—On April 22nd, at 16, Waldemar Avenue, Ealing, the only son of the late Henry Minchan Carden-Noad, Ph.D., F.R.S., Henry Carden-Noad, L.R.C.P. Lond., M.R.C.S.Eng., in his 67th year.

Marvin.—On April 24th, suddenly, of pneumonia, Harry Forbes Churton, M.R.C.S., L.R.C.P., elder son of Lt.-Colonel W. Marvin, late Army Pay Department.

Prangley.—On April 24th, at Tudor House, Anerley, Henry John Prangley, M.R.C.S., L.R.C.P., aged 50.



K.&O. DOUCHE FOR THE APPLICATION OF GLYCO-THYMOLINE TO THE NASAL CAVITIES

GLYCO-THYMOLINE

IS USED FOR CATARRHAL CONDITIONS OF MUCOUS MEMBRANE IN ANY PART OF THE BODY

Nasal, Throat, Stomach, Intestinal Rectal and Utero-Vaginal Catarrh

KRESS & OWEN COMPANY - 210 Fulton Street, New York

Sole Agents for Great Britain, THOS. CHRISTY & CO., 4—10 & 12 Old Swan Lane, London, E. C.

Examined and approved by the Institute of Hygiene, 34 Devonshire St., Harley St., W., where this preparation can be seen, and its properties and value can be explained.

Xeroform An absolutely non-poisonous desiccating, and deodorising **Dusting Powder** for wounds. Actively promotes the growth of epithelium, and does not irritate either the wound or the surrounding skin. Excellent for dry dressings and also for dressings which are seldom changed. Has a specific action on **Moist Eczema, Ulcers of the Leg,** and **Burns.**

Collargol An admirable remedy in **Septic Processes, Puerperal Diseases,** etc. Administered intravenously it produces no ill-effects of any kind. It may also be given by the rectum, or by the mouth, or by inunction in the form of **Credé's Ointment.** Useful in the treatment of **Wounds** and **Infectious Diseases of the Eye** and for **Washing out the Bladder.**

Salit A Salicyl Compound in the liquid form. Moderate in price and gives immediate relief when rubbed on the seat of pain in **Rheumatism.** Does not injure the skin even when undiluted. Has no ill effect on the internal organs.

Novargan A Soluble Albumen-silver Preparation for the treatment of **Gonorrhœa,** especially in the **acute** stage. Even in the concentrated form it does not irritate the mucous membrane.

Samples and Literature may be obtained of . .

E. W. BLASIUS, 127 **Fenchurch Street, London, E.C.**

Telegrams: "Kreosot, London." Telephone: 1876 Avenue.

SOLE AGENT FOR

CHEMISCHE FABRIK VON HEYDEN, Radebeul, near Dresden.

MILO FOOD

is based on Science and the Practical Experience of Thirty Years. It is a Food with Milk as a basis.

By the simple addition of water in the proportion indicated in the instructions accompanying each tin, **MILO** adapts itself to children of various ages.

MILO

is much appreciated by nursing Mothers, and is invaluable at the time of weaning.

Awarded the GOLD MEDAL at the CAPE TOWN EXHIBITION, also the CERTIFICATE OF MERIT by the INSTITUTE OF HYGIENE, LONDON.

Sample and pamphlet on "The Feeding and Care of Infants" sent free to Mothers and Nurses on application to

NESTLE & ANGLO - SWISS CONDENSED MILK CO., 6 & 8 Eastcheap, London, E.C.

MODERN THERAPY

Aromatic Antiseptics.

ALKATHYMOL (P., D. & CO.)

Each fluid ounce contains:—

Sodium Biborate	4 grains
Sodium Bicarbonate	8 „
Sodium Chloride	8 „
Sodium Sulphate	3 „
Sodium Phosphate	1 grain
Menthol	1-2 „
Thymol	1-4 „
Eucalyptol	1-8 minim
Oil of Pinus Pumilio	1-8 „
Chloretone	1-4 grain
Glycerin	60 minims

Therapy.

A non-irritant, alkaline antiseptic for use in catarrhal conditions of the nose and throat; as a disinfectant gargle and mouth-wash; as a curative and sedative application in dermatitis, cutaneous irritations, insect stings, etc.; and as a douche in leucorrhoea, and other uterine affections.

Excellent as a dentifrice, exerting a salutary influence on the gums, and counteracting the causes of dental decay.

EUTHYMOL (P., D. & CO.)

Each fluid ounce contains:—

Oil of Eucalyptus	3-8 minim
Oil of Gaultheria	9-32 „
Fluid Extract of Wild Indigo	1 1-4 minims
Boric Acid	10 15-16 grains
Menthol	5 64 grain
Thymol	15-32 „

DOSE—One fluid drachm.

Therapy.

A non-poisonous, non-irritant antiseptic, possessing a wide range of usefulness in medicine, surgery, and obstetrics, as well as in toilet and domestic hygiene.

Valuable in genito-urinary diseases; as a soothing application to stings, burns, and ulcers; as a gargle in throat affections; and as a general, mild, innocuous disinfectant.

EUFORMOL (P., D. & CO.)

Each fluid ounce contains:—

Oil of Eucalyptus	3-8 minim
Oil of Gaultheria	3-10 „
Thymol	1-2 grain
Menthol	1-12 „
Boric Acid	12 grains
Fluid Extract of Wild Indigo	1 1-4 minims
Formaldehyde (40 °/₀)	60 „

Euformol is largely used for disinfecting faeces, as in typhoid fever, etc. Mixed with an equal volume of water and sprayed about the sick-room, it is a refreshing deodorant, and prevents the spread of infection.

Therapy.

A potent germicide and deodorant. Diluted with from five to twenty volumes of water, it is of great service as a lotion in bromidrosis, and as a douche in ozaena; also as a stimulant and disinfectant of ill-conditioned ulcers.

Equal volumes of Euformol and glycerin are used as a spray in diphtheria and ulcerated throat, also, well diluted, as a uterine douche in puerperal fever.

Inhaled from cotton wool or hot water, Euformol is valuable in phthisis, pertussis and catarrh. It may be applied undiluted in lupus, ringworm, and parasitic skin diseases.

Please specify "P., D. & Co." on all prescriptions for the above-mentioned preparations. They are supplied in bottles of 4, 8, 16 and 80 fluid ounces.

PARKE, DAVIS & CO.,

50-54, Beak Street, Regent Street, London, W.

167

The LONDON MEDICAL RECORD says:

"We have found it invaluable for old people, whose digestive powers are feeble, and also in convalescence from acute diseases."

BENGER'S FOOD

For Infants, Invalids, and the Aged.

GOLD MEDAL AWARDED Health Exhibition, London, Adelaide and Melbourne.

When mixed with warm new milk, or milk and water, the digestive principles contained in the Food not only render the farinaceous elements soluble, but further, reduce the casein of the milk to a condition similar to that existing in human milk, so that hard indigestible masses cannot be formed in the stomach. The degree of digestion can be regulated.

BENGER'S FOOD with milk forms a delicate and delicious cream, rich in all the elements necessary to maintain vigorous health.

IT IS ENJOYED BY INFANTS, INVALIDS, CONVALESCENTS, AND THE AGED.

☛ *Sample, Analysis, and Report sent upon application to any member of the Medical Profession.*

BENGER'S FOOD may be obtained in various sized tins of leading Chemists, etc., everywhere ; wholesale of all Wholesale Houses ; or of

BENGER'S FOOD, Ltd., Otter Works, MANCHESTER.

Telegraphic Address : "BENGER'S, MANCHESTER."

TRADE MARK.
A.D. 1715.

"A distinct advance on Easton's Syrup."

—The Lancet.

"Bynin Amara"

'BYNIN' AMARA is an analogue of Easton's Syrup, in which the sugar is replaced by an active Malt Extract. This affords a far better vehicle than syrup, as it is actively digestive and nutritious, and there is not the likelihood of the sugar crystallizing out, and carrying down in the crystal the alkaloid principle.

As a digestive tonic, therefore, 'BYNIN' AMARA is not only safer to take than Easton's Syrup, but is of greater value both in aiding and strengthening the powers of assimilation.

It has been found very effective in neuralgia and similar nerve troubles.

COMPOSITION.

Quinine Phosphate	1½ grains.
Iron Phosphate	2 „
Nux Vomica Alkaloids equal to Strychnine	$\frac{1}{16}$ „
'Bynin, Liquid Malt	1 ounce.

DOSE FOR ADULTS—One dessert to one table-spoonful, suitably diluted.

A Sample Bottle will be sent free to Medical Men, on request.

ALLEN & HANBURYS Ltd.,

37, LOMBARD STREET, LONDON, E.C.

UNITED STATES: Niagara Falls, New York.
CANADA: Gerrard Street East, Toronto.
AUSTRALASIA: Bridge and Loftus Streets, Sydney.
SOUTH AFRICA: Castle Street, Cape Town.

"SCOTT'S Emulsion to prevent Colds"
"And Influenza."
"Builds up the System."

——— ———, *Orkney, January 18th, 1906.*

EVIDENCE:

"Dear Sirs,—I find the greatest benefit from your elegant preparation, SCOTT'S EMULSION, both in preventing colds and influenza and also in building up the system after such complaints. It has done much good in a recent case of positive phthisis."

Yours sincerely,

——— ———, *M.D., Glasg., L.F.P.S. Glasg.*

16 oz. Bottle, with formula, free to any physician, surgeon, or certificated nurse desiring to test SCOTT'S EMULSION.
SCOTT & BOWNE, LTD., 10 and 11 Stonecutter Street, Ludgate Circus, London, E.C.

BROMURAL (Knoll)

(α — Monobrom — iso — valerianyl — urea).

As regards its action, it occupies a position midway between the hypnotics on one hand and the bromides and valerian preparations on the other. It is a

HARMLESS, POWERFUL NERVE SEDATIVE AND MILD HYPNOTIC,

which causes no by or after-effects, and forms the preliminary for a short, healthy, dreamless sleep, from which the patient awakes fresh and invigorated.

DOSE:—
as a sedative, - - - 5 grains several times a day.
as a hypnotic - - - 10 grains before bedtime.

KNOLL & CO., 8, Harp Lane, London, E.C.

NOTES AND COMMENTS.

Inebriate Committee. IN accordance with his promise, the Home Secretary has now appointed a Departmental Committee to inquire into the law relating to inebriates, the detention of the latter in reformatories, and to recommend what alterations in the law or its administration are required. Reform in this direction has been long and urgently needed, and we are most thankful to see that an effort is being made to bring it about. At the risk of seeming ungrateful, however, we cannot but express disappointment that a reference to a Departmental Committee has been deemed sufficient. In our opinion this is not a departmental matter at all, but a national one of far and wide-reaching importance, involving the liberty of the subject at many points. A Royal Commission is the only body capable of handling such a question in the manner it deserves, and we fear that the report of the Departmental Committee will not be deemed of sufficient weight to authorise those large changes in the law which alone can render the position of the inebriate one of less disadvantage to society and of greater protection to himself. Admittedly the timid measure introduced by the late Lord Ritchie has failed entirely, as it was predestined to fail, but if it had only shown how comprehensive any legislative enactment must be to have any chance of success, it would not have been without value.

Needed Powers. IT is plain to medical men and others who have experience of drunkenness in the various classes of society, that inebriates, once established in their habits, are a well-nigh hopeless class to deal with, except under wide and strong powers. The object of society should be not to translate a few Jane Cakebreads from the prison to the reformatory when they are in a degenerate and parlous condition, but to attempt to give properly-constituted authorities a commission to prevent those who give way to drink from squandering their health and their property, from abusing the rights of citizenship and the duties of the family, and from committing crimes and outrages, through indulgence in stimulants. The only way to treat these questions efficiently is to give the State power over the drunkard such as it possesses over the lunatic. The medical profession know, as no one else knows, the impotence of themselves and everybody concerned in preventing drunkards from obtaining stimulants and carrying on their disastrous careers. Every member of the profession must hundreds of times have wrung his hands hopelessly while men have dissipated their businesses and women ruined their homes through indulgence in alcohol, and, together with the relations of their patients, have bemoaned their inability to take any step to prevent the evil that they see. Only by certificate and guardianship, either in an asylum or at home, can any adequate restraint be exercised.

Drug Habits. BUT, pressing as is the need for such drastic treatment of inebriates, hardly less so is that of narcomaniacs and drug-takers. Although exact figures are impossible to obtain, medical men generally are agreed that the increase in self-drugging with sedatives has been enormous, and that what drink is to men, drugs are to women. The best pharmacists are often unable, or unwilling, to refuse to supply drugs which they know are taken in excess, and the institution of co-operative chemical stores and the putting-up of powerful drugs into tablet form, have given an enormous impetus to the habit by granting increased facilities and removing any check the medical attendant can exercise. We feel that the communal treatment of inebriety which does not embrace in its province the restraint of the drug-taker, is likely merely to divert the morbid impulse into another and almost more hopeless channel. We trust the Departmental Committee will ask that its powers may be extended in this direction before it settles to its work. As constituted, with the exception of one or two untried persons, the Committee is an excellent one, and we especially welcome the name of Dr. Mercier, whose experience and acumen are so well recognised in the profession, and whose non-official position will enable him to pursue the original line that he pursues so successfully in matters of morbid psychology.

Motor Taxation. IN the new Budget confident rumour says that additional taxation is to be put on motor-cars. In the general way no objection could be taken to such an impost, for motor-cars are the luxury of the rich and entail a heavy burden on those who are poor by the damage done to roads, and by the decreased pleasure in walking and bicycling which cars travelling at a high rate of speed entail. But, in justice to the medical profession, we hope that the Chancellor of the Exchequer will see his way to exempt them from such a tax. The advent of the motor has already somewhat altered the conditions of practice, and it will do so still more in the future. By increasing the range of a single man's activity, it has made competition keener, and many medical men are finding that without a motor their chances of keeping up their practice are more and more difficult. Many such can ill afford the capital outlay and the extra annual expenditure, but in self-defence they feel bound to incur it, and any fresh burden will press very hardly. No man who owns a car can honestly say that it is used solely for the purposes of his profession; naturally the owner employs it as occasion offers for himself and his family, but the proportion of medical men who would buy a car unless forced to do so for professional purposes must be very small. A medical man's car should be treated as part of his professional expenses, and a tax which presses on trade or professional means of communication is notoriously bad.

Women Referees.

A QUESTION was asked in Parliament last week as to the number of women who come under the provisions of the Workmen's Compensation Act, and whether the Home Secretary was placing any women-doctors on the list of medical referees or medical assessors, so that women claiming under the Act might have the benefit of their services if necessary. We do not know what influences were at work to get the question put, but it is one involving a principle that cannot too strongly be deprecated. The advent of women into the medical profession may or may not be a good thing; the decision of that point, either in the affirmative or the negative, is entirely beside the question. But, unhesitatingly, it is a bad thing if it raises the further question as to there being any undesirability or impropriety in men attending female patients. In other words, a medical man, when he advises a woman who seeks his services, should be above suspicion, and it is a fact that any transgression against this rule is visited with the severest penalties by the disciplinary machinery of the profession. In our opinion it is more than unfortunate that any suggestion to the contrary should enter the public mind, and we believe women doctors in the aggregate would join us in reprobating it. To the particular question in point Mr. Gladstone replied that, although there were three million women affected by the Act, only two references to referees took place last year in which women were affected, and that the practical difficulties of making appointments were too great to be overcome, but that he would always consider an *ad hoc* reference to a woman practitioner. Which seems a very sensible conclusion to come to.

Non-Alcoholic Claret.

A MILD shock was lately administered to teetotallers by the returns of the Government Analyst, which showed that ginger-beer and other harmless, necessary drinks contained proportions of alcohol running to 3 per cent. and more. Except to those who hold the very name of alcohol in horror, this *exposé* need cause no surprise or regret, for the quantity of liquid that would have to be consumed before the drinker got any "forrader" would be so enormous that the subject would be certain to desist from mere distension long before his higher centres showed evidence of unnatural stimulation. We would trust Mr. Stiggins himself in a cellar of ginger-beer—provided there were no pine-apple rum there as well. But the sapping of principle which indulgence in ginger-beer denotes has led the way to another beverage being admitted into the category of teetotal delights. This beverage is no other than claret. At Boston, last week, a publican was charged with serving alcohol to a man on the black-list, and he put forward as his plea that he only supplied the delinquent with that non-intoxicating drink, claret. A local teetotaller supported the "trade" by testifying to his habit of drinking claret on occasions, and a chorister, who was always an abstainer during Lent, also said that he and his teetotal friends all took claret during that close season. If these be modern views, we can only imagine what the indignation of our early Georgian ancestors would have been had they heard claret described as non-intoxicating; and for our own part, we confess, that the pledge would press but little hardly on us while we were permitted to indulge without stint in that very prince of wines.

LEADING ARTICLES.

WHY IS NOT TUBERCULOSIS PREVENTED?

THE problem of tuberculosis and its extinction has been forced upon the attention of the community in so many ways and over so great a period of time that there is some danger of a reaction unless satisfactory results are forthcoming. It is of no little significance that the discussion of the subject is now mainly carried on in the lay, as apart from the medical journals. The progress of our scientific knowledge with regard to tuberculosis has been rapid within the last quarter of a century, and the public has firmly grasped the principle that the malady must be ranked among the preventible diseases. As a matter of fact, the response of the nation to philanthropic appeal has been prompt and not ungenerous. Huge and often costly sanatoria for the treatment of consumptives have been erected in various parts of the kingdom, and municipal and Poor-law institutions have been also founded for the same purpose. In spite of these efforts, however, it must be acknowledged as a fact beyond dispute that the national means for the adequate treatment of tubercular patients are absolutely incomplete, inadequate, and unsatisfactory. Of the total number of sufferers only a small proportion can be accommodated; many are in an advanced stage in which sanatorium treatment is of little or no use; while of those who find relief it is in many instances impossible to keep them long enough to ensure a complete cure, or, when a cure has been effected, they are often perforce sent back to the inevitable environment in which the disease was originally contracted. At the same time it is clear that an immense amount of good and useful work is performed by special sanatoria. Indirectly, they isolate a considerable sum-total of infection, and they further discharge a valuable function in the education of the public. For it is in these and similar preventive directions, rather than in curative measures, that the future elimination of tuberculosis lies. It is therefore desirable to ask ourselves whether, as a nation, we are reasonably acting up to the teachings of modern science in dealing with this great physical scourge. Take the two great principles of sanitary administration that sprang into existence directly the identity of human and bovine tuberculosis was definitely established, namely, the necessity of a rigid exclusion of tuberculous milk and meat from the national food supply. So far as milk is concerned, it may at once be stated that the system has yet to be devised which shall ensure that milk shall not be obtained from cows suffering from tuberculosis. In other words, the first, obvious, and elementary step in the reduction of the mortality and suffering from human tuberculosis has not yet been taken. Philanthropists and economists who bewail the excessive infantile mortality that is a standing reproach to our science might with advantage devote themselves to the practical task of ensuring the purity of the milk supply, at any rate, so far as the germs of tubercle are concerned. As to the flesh of animals intended for human consumption, precisely similar arguments, *mutatis mutandis*, may be applied. It is certain that infected meat can convey the virus in an active condition. It is equally certain that the specific micro-organisms may retain their vitality after running the gauntlet of cooking operations. It is obvious that the machinery of meat inspection is, under present conditions, crude and unscientific in method, and defective in application. The situation, indeed, may be summed up in the general statement that the nation is not at present effectually guarded against the infection of tubercular disease by means of a specifically infected food supply. The question naturally arises: How are these things to be remedied? The answer is somewhat complex. In the first place, it will be necessary to educate the public to the proper pitch, and to show them the practical benefit likely to accrue from preventive measures. The Local Government Board can do much, but it is likely that in the long run it will be necessary to strengthen the administrative arm by fresh legislation. Existing Acts regarding dairies, purity of food, and public health generally, will probably require amending in various directions. It is to be hoped that before long the legislature will turn its attention to the great questions involved in the final campaign against what has been aptly termed the "white scourge." The work has been well begun, but for the moment is almost looks as if British sanitarians were relaxing their grip of the practical side of things. The vastness and complexity of the problem, to say nothing of the vast expenditure that is involved, may account to some extent for this apparent pause. We have every confidence, however, that the sturdy pertinacity of our race, which has proved of supreme value in the conquest of many no less deadly scourges, will ultimately prevail against one of which the ultimate secrets have been disclosed by the labours of modern medical science.

CURRENT TOPICS.

Cancer Research and the Middlesex Hospital.

AN appeal is being made through the press by Lord Cheylesmore for funds of sufficient magnitude to endow the Cancer Department of the Middlesex Hospital, and make it independent of fluctuating subscriptions. The profession will cordially support the request, especially those members of it who have watched the excellent and unostentatious work which has been carried out there for the last eight years. The only objection conceivable is, that the work of the Middlesex might overlap or adversely compete with that of the Cancer Research Fund. We do not think this is, or is likely to be, the case. In the first place, the Middlesex Hospital has the advantage over the Fund of having clinical opportunities of testing accredited remedies, as well as the more academic facilities. The Hospital has done much good work in this direction already, principally, alas! of a negative character, but it enjoys unusual facilities of putting any promising plan to the final and decisive test; and it is by no means improbable that to the Middlesex may belong the "crowning mercy" of establishing a method of curing the disease. As to competing scientifically with the Fund, such rivalry is of an entirely healthy character, and the two agencies are far more likely to stimulate each other than to waste time and material in going over the same ground. In research work there is an inevitable tendency to disheartenment when avenue after avenue has been followed up and found to be blind. The best correction to such disappointment is to know that there are others working along other lines which may be more successful, unless every effort is put forward to keep abreast. But in any case, by the enthusiasm shown at the Middlesex, by the good work put in by many past and present workers, and by the prudent management of its affairs, the appeal stands on the strongest ground, and we feel sure that the wealthy, especially such as have seen their relatives suffer from cancer, can find no better outlet for their benevolence to humanity than by subscribing handsomely to the Department.

Human Freaks and the Public.

THE exhibition of so-called human "freaks" has been brought to the level of a fine art by the wiles of the American showman. One of his favourite captures is the "ostrich man," who swallows all kinds of solid articles, from tin-tacks to glass tumblers and open clasp knives. Sooner or later this unhappy juggler is unable to disburthen his stomach of its unnatural load, and he dies a miserable death, for a surgical operation is almost invariably unsuccessful. It is a question of public morality whether persons who assist as spectators at these unnatural performances do not become accessories to the fatal issue. At any rate, it is certain that, were there no fees from the audience, there would be a speedy end to this particularly deadly exhibition. In these days when there is so much cheap philanthropy abroad it is difficult to understand why the dangerous performance has reached a pitch of popularity that it has probably never before attained. Another curious fact is that the State, which is exerting itself to protect life and limb in almost every conceivable condition of social environment, has left the dangerous performer to risk his neck in a score of ghastly ways for the sake of earning his sorry livelihood. Of course, some of the "freaks" are merely harmless specimens of diseased processes, such as the giant, the dwarf, the "blue man" (coloured by nitrate of silver), and the fat woman. One of the most pitiable of all these pathological curiosities is the subject of advanced progressive muscular atrophy who is exhibited under the not altogether inappropriate title of the "living skeleton." As a rule he is one of the greatest attractions possible in this particular class of exhibits, and his salary—while it lasts—is equal to that of many a first-class barrister or fashionable physician.

A Sleeping Sickness Prevention Ordinance.

THE Governor of Uganda has promulgated an Ordinance for the prevention of sleeping sickness. He has thereby placed a vast part of territory under the conditions of a declared infected area. Stringent rules are laid down for the whole of the mainland of the Uganda Protectorate within a distance of two miles of the Victoria Nyanza and all the islands in the Victoria Nyanza. Fishing is prohibited within two miles of the shore, and the purchase of fish caught within that area is a punishable offence. No person is permitted to ply on the Victoria Nyanza. Traffic is permitted between the islands and the mainland only under certain strictly-defined conditions, including the use of special landing-places. The importance of strict preventive rules of this kind in the heart of Africa marks a new departure in the relation of the British Government to her native dependencies. If we recognise our moral responsibility in stamping out sleeping sickness in Uganda it is not easy to see logically why we are not compelled to bring an equal amount of energy to bear upon, let us say, cholera in India. On the whole, it is probably as easy, or easier, to banish cholera than to exterminate sleeping sickness. To have discovered the cause of the last-mentioned malady is a fact of which modern medicine may well be proud, and to rid the world of its presence will constitute a still nobler indication of the practical value of science to mankind.

A Proposed Official Register for Nurses.

A proposal is contained in the Bill recently introduced into the House of Lords by Lord Balfour of Burleigh, to "provide for the establishment of an Official Directory of Nurses." In the absence of sound evidence to the contrary, most medical men would probably regard the step therein indicated as a work of supererogation. The present system works fairly well, and it would be nearly as reasonable to demand a State registration of chefs, or lawyers' clerks, or watchmakers, or for members of any other class of skilled workers. Indeed, the claim has been seriously and repeatedly advanced in the case of the plumbers and the spectacle-makers. Were the principle of registration once generally accepted the world of industry would run a risk of becoming converted into a mass of isolated monopolies, each one struggling to wring the uttermost farthing from the pockets of the consuming public. From the economic point of view we imagine it would be an evil day for the community should nursing be made a monopoly. If there is to be a State registration of nurses—which we regard as an absolutely uncalled-for departure— there can be no logical objection to the establishment of an official Directory. The one appears to be dependent on the other. The State could hardly issue an official *Register* without having fixed upon its standards of education and of examination, and without the creation or the co-option of its educational examining bodies. If Lord Balfour proposes merely to issue a list of nurses who can produce satisfactory certificates of training and of moral character short of a State diploma, he is seeking to do what would probably be accomplished just as well, or better, by private enterprise. The whole movement appears to be a natural extension of the worst features of the Midwives Act, whereby a particular branch of nursing, useful and honourable in itself, has been translated into a false position of a semi-demi State-qualified medical description.

Diphtheria from Cats.

The times seem favourable for a critical review of the relations between mankind and domestic animals with regard to infection. The future control of tuberculosis in a great measure depends on the way in which the comparative disease is handled by the local and national health authorities. The list of diseases which are mainly or altogether due to the agency of the lower animals is extensive. Such maladies as influenza, glanders, plague, actinomycosis, anthrax, trichiniasis, and most kinds of tapeworm, will occur at once to the medical reader. It is not unlikely that many of the specific infectious diseases may be communicated to man either mediately or immediately by the agency of domestic animals. Many cases have been reported, though on scant authority, in which scarlet fever, small-pox, and other fevers have been attributed to infected horses, cats, or dogs. In Swindon recently two children died from diphtheria, the infection in each case having been traced to the household cat. The chain of evidence was rendered complete by the identification of the disease in the cats by the Medical Officer of Health for the district, Dr. F. E. Streeten. The fact that cats may not only contract the disease, but spread it broadcast cannot be too widely known. There is no more insidious bacterial foe than that which appertains to diphtheria. At the same time, there is a silver lining to the cloud in the fact that it is absolutely preventible, and one day will assuredly be prevented.

Medicine in the Royal Academy.

As a not unimportant factor in social life the world of medicine comes in for a fair share of attention at the hands of the painters at the Royal Academy. This year one of the chief pictures illustrates an incident of professional life. It is from the brush of the Hon. John Collier and displays his air of absolute realism and fine sense of drawing and colour. Apart from the title, however, it would be impossible to say from merely looking at the picture what particular tale it is intended to convey. A business-like, intellectual-looking consultant is giving advice to a young man who is obviously not in good health. Beyond that it would be unsafe to attempt to draw any inference of any value, although it is clear enough that a wide field of conjecture is thrown open to any of those who care to exercise their imagination. On the whole, the proposition most likely to suggest itself to the mind of the medical man would be that the patient is suffering from tuberculous disease. To that speculative diagnosis, however, there would be many equally possible alternatives, if it be allowable to apply that much-abused term to more than one possibility. For instance, the youth might be convalescent from some acute infectious fever or severe accident; he might be the victim of melancholia or some spinal cord lesion, or may have turned the midnight oil too freely. As a matter of fact, the precise position of affairs is indicated by the catalogue title, "The Death Sentence," whereby the artist indicates that the physician is communicating the fact that his patient is afflicted with a fatal malady. The situation is dramatic and full of the sudden pathos and tragedy that often flits across the path of a busy medical man.

Royal College of Surgeons in Ireland and the University Bill.

Mr. T. W. Russell has informed Sir William Collins in the House of Commons during the past week that it is not intended to make the Royal College of Surgeons in Ireland a constituent

College of the new University in Dublin. In reply to a further question, he stated that Mr. Birrell would be prepared to sonsider any further representations which might be made by the College of Surgeons. We understand that it is probable that the Royal College of Physicians will join with its sister College, and certainly this is the wise and obvious course to be taken. The College of Surgeons naturally fears lest its School should be overshadowed by the School of the new University supported by large Government grants. Even if that did not occur, another danger would lie in its path, namely, the difficulty of overcoming the probable prejudice of local bodies through Ireland to men who are not trained at the new University. For that reason, we think that the Colleges should together try to obtain an undertaking from Government to adopt without delay the Report of the Poor-law (Ireland) Commission, and to institute a Poor-law Medical Service, entry into which should be by competitive examination, instead of by the present demoralising methods. The Colleges must fight strenuously if they are to maintain their position, and if, in their effort to do so, they succeed in getting this report adopted, they would incidentally confer a benefit on the whole country.

A Dublin Surgeon of Elizabeth's Time.

It is interesting to learn of the high position occupied by members of our profession in Ireland at a time when in some other countries surgery was still a more or less despised craft. In a recent lecture, Dr. George Sigerson has recounted the life of a surgeon who took an honourable and conspicuous part in the civic life of Dublin in the time of Elizabeth. This was John Morphe, who seems to have been a pupil of that Denis Collier, "phisician and surgeon," who so "adventured his life in this contagious time of plague" in 1575, that he was admitted to all the liberties and appointed medical officer of the city. Morphe, who was a native of the County Dublin, and was allied with many of the gentle families of the Pale-Gaelic, Norse, and Norman periods, prospered so in Dublin practice that he became, for those times, a very rich man. He was an alderman and a sheriff of the city. His interest in public affairs was further shown by his bequests for the purpose of building bridges over the Dodder and Tolka. He left much money in charity and to various churches in which he was interested. One bequest of special interest is that to the Company of Chirurgeons of "one of my Silverton cupps and the heavy chist that is in the little chamber in the forestrete to kepe thyr wrythings in memory of me that wyssh to them encrease of vertuous knowledge." In the increase of virtuous knowledge which has come to the Dublin surgeons the memory of John Morphe should not be forgotten.

PERSONAL.

The King has been pleased to give directions for the appointment of Joseph E. Godfrey, M.B., Surgeon-General, and Chairman of the Local Government Board of British Guiana, to be a member of the Executive Council of that Colony.

His Majesty the King of Italy has been pleased to confer upon Dr. Thomas Reid, of Glasgow, the order of the "Commendatore of the Crown of Italy." This distinction is designed as a recognition of Dr. Reid's merit as an ophthalmic surgeon and also of his many services to the Clinique of Ophthalmology in the University of Turin, where his intimate friend Professor Reymond is chief.

Dr. Henry Gervis has been appointed a magistrate for the Borough of Brighton.

The German Emperor has conferred the Order of the Crown, Second Class, on Sir Felix Semon, K.C.V.O.

There is considerable improvement in the condition of Dr. Rainy, M.P.

We regret to hear that Dr. Spinks, of Bournemouth, was injured in the head and arm by the terrible tram accident last week.

At the London Hospital, Mr. G. P. Mudge will lecture on "Mendelian Inheritance" on May 6th and May 13th, at 4.30 p.m.

Professor Osler will deliver the Linacre Lecture at Cambridge on May 6th, taking as his subject "Thomas Linacre—His Life and Works."

Surgeon-General G. D. Bourke, C.B., Principal Medical Officer in Ireland, has been appointed to be a Governor of the Westmoreland Lock Hospital.

Dr. Octavia Lewin's goods, which were seized for non-payment of a fine of £10 for refusing to pay tax on armorial bearings, were sold by public auction on May 4th.

The new Glasgow Maternity and Women's Hospital was opened on April 24th, the ceremony being performed by the Duchess of Montrose, who was accompanied by her daughter, Lady Helen Graham.

An Association of Tropical Medicine has been formed in the Far East, and Dr. Paul C. Freer, Director of the Bureau of Science in the Philippine Islands, has been elected the first President.

A presentation has been made to Professor J. G. McKendrick, of Glasgow, on his retirement. It took the form of his portrait, to be hung in the University Buildings, a silver tray, and a sum of £450 to equip a laboratory of experimental psychology.

Mr. John Morley, on his elevation to the peerage, will probably assume the title of Viscount Morley of Blackburn. His father, Mr. Jonathan Morley, practised as a medical man in Blackburn, and Lord Morley was born there 70 years ago. He entered Parliament for Newcastle-on-Tyne in 1883.

A Hospital for Women and Children has been given to the city of Madras by Deman Bahadur N. Subrahmanyam. The donor stated that he proposed to hand over the hospital to the Wesleyan Society, which had sent out Miss Wilson, a graduate of Aberdeen University, as lady superintendent.

The fund being collected as a memorial to the late Dr. J. Everett Dutton, who died a year or two ago when on an expedition for the Liverpool School of Tropical Medicine, is nearing completion. More than two-thirds of the sum required has now been given or promised, the activity of Sir Rubert Boyce being largely responsible for this happy result.

The Annual Dinner of the Association of Scottish Medical Diplomates will be held at the Hotel Waldorf, Aldwych, London, W.C., on Tuesday, May 26th, the President, Dr. David Walsh, in the chair. Tickets, 10s. 6d. each (exclusive of wine) may be obtained from Dr. Arthur Harries, 11 Chandos Street, Cavendish Square, London, W. Ladies are invited, and any holder of a Scottish qualification will be welcomed.

Dr. Thomas Lambert Hinton, of St. Leonards, has just celebrated his one hundredth birthday. He and Sir Henry Pitman are the oldest members of the Royal College of Surgeons. Dr. Hinton has a distinct recollection of hearing the result of the Battle of Waterloo. From 1829 to 1846 he served in the 1st Bengal Fusiliers. On his way home from India he was wrecked oft Cape Finisterre. While in the water a child was flung to him, and he swam with it for a long time before being rescued.

A CLINICAL LECTURE
ON
EARLY DIAGNOSIS IN SURGICAL DISEASES OF THE KIDNEY, WITH SPECIAL REFERENCE TO PHYSICAL METHODS OF EXAMINATION.

By DAVID NEWMAN, M.D., F.F.P.S.G.,

Surgeon, Royal Infirmary, Glasgow.

FEW diseases occurring in surgical practice more clearly illustrate the value of early diagnosis than do the commoner surgical maladies which attack the urinary organs. These include tuberculosis, septic infection, and calculus, all of which, while they. as a rule, start in the kidney, rapidly lead to serious secondary changes in the lower portion of the tract.

A belief, unfortunately, prevails that infective diseases such as tuberculosis and septic lesions usually begin in the bladder or genital organs, and spread upwards to the kidneys, whereas it is now well-known that exactly the opposite mode of invasion is the rule. The natural conclusion to be drawn from this circumstance is that it is the duty of the medical adviser to discover not only the nature of the morbid process, but to fix as early as possible its exact locality.

By inference from symptoms alone this is almost impossible except in typical cases; but in actual practice how many such cases do we meet with? The subjective phenomena are too often misleading—pain being the least reliable of all. Often renal calculus, for example, causes no suffering in the region of the affected kidney, the only complaint being pain at the point of the penis or in the bladder.

Symptoms simply point the direction in which information may be obtained—nothing more. For example, pain and bleeding may originate in any portion of the urinary tract, but, while in many instances the character of the hæmorrhage and the situation of the pain correctly indicate the nature and site of the lesion, in others they seriously mislead, unless resort is had to physical proofs to guide and correct the inferences deduced from the subjective symptoms.

The objective methods which are most valuable in aiding an early and exact diagnosis are:—

(1) Bacteriological examination of the urine, inoculation experiments and ophthalmo-tuberculin reaction.
(2) Segregation of the urine.
(3) Sounding.
(4) Cystoscopy.
(5) Methylene blue test.
(6) Radioscopy.

To a consideration of these attention will be limited, taking it for granted that they are employed only as aids to the ordinary methods of clinical inquiry as to the general symptomatology, and in conjunction with the facts revealed by inspection, percussion, palpation, surface, abdominal ballottement, rectal and vaginal, auscultation, rectal insufflation, and a careful examination to ascertain the condition of the urine as regards pus, blood, or other abnormal constituents.

1.—BACTERIOLOGICAL EXAMINATION OF THE URINE.

The first difficulty which presents itself in a bacteriological examination is to obtain the urine free from external contamination. To make a reliable observation, the urine must be conveyed from the bladder to a sterilised vessel, all risk of contamination being obviated. How, then, are we to proceed? The appliances—namely, Melchior's catheter, tubing, and collecting vessels—must be sterilised by boiling in an alkaline solution, and afterwards washed in sterilised water; the glans penis and the prepuce, but especially the meatus, must be thoroughly washed with soap and water containing a little ammonia; this is followed by washing with spirits of wine, and afterwards with carbolic acid solution, 1 in 40 in water. The meatus should also be douched with sterilised water; afterwards the mucous membrane should be carefully everted and again thoroughly cleansed. All the parts of the patient having been thoroughly disinfected, the surgeon again cleanses his hands and lubricates the catheter with glycerine containing carbolic acid 1 part in 40, and passes it into the bladder. The urine is allowed to flow direct into the previously sterilised tubes of the centrifugal separator, and after a few minutes in the machine any deposit of microbes is thrown down, and can be at once examined microscopically, or by culture observations. The advantages of this rapid method are obvious.

The organisms which invade the urinary tract may be divided into two classes—those which induce decomposition of the organic constituents of the urine, and those which cause little or no chemical change in these substances. This distinction is a very important one. When organisms which do not possess the power of decomposing the organic constituents of the urine are introduced into the healthy urinary tract, they fail to produce any serious effect. For example, a pure culture of the bacillus coli, or of the tubercle bacillus, may fail to induce cystitis when injected into the uninjured bladder, but if separately, or along with them, urea-decomposing organisms are introduced, acute cystitis is sure to follow. When the infection is "mixed," the progress of the disease is usually very rapid. The principal organisms which induce decomposition are the staphylococcus pyogenes aureus and albus, some staff bacilli, and diplococci.

The *bacillus coli communis*, first recognised in 1886 by Escherich, is normally found in the intestine, but in diseases affecting the alimentary tract the number is enormously increased, and in certain well-known conditions the virulence of the organism is intensified.

In the urinary passages, as elsewhere, the virulence of the bacillus coli varies according to circumstances. In some cases its presence causes little or no disturbance, while in others its virulence is great, and death may take place even before suppuration is established, as in acute septic interstitial nephritis. The bacillus coli is by some observers supposed to be the most frequent cause of inflammation of the urinary tract, being in most instances absorbed into the circulation through lesions in the intestine and deposited in the kidney. This occurs most commonly when the intestinal tract is obviously diseased. It is found, as a matter of experience, that pyelitis or septic nephritis comes on very commonly in the course of convalescence from enteric fever, dysentery or acute diarrhœa. The bacillus coli or its products probably also plays an important part in the ætiology of certain nervous lesions associated with chronic inflammatory diseases of the urinary tract.

In the intestine it is clearly non-pathogenic, but when it migrates to other parts it is strongly pathogenic. The soluble products of the growth of the bacillus seem to be the same in their action whatever may be the medium employed, but the source from which the organisms are derived has a very important influence on their action. As an illustration of this, the organisms taken as a pure culture from a peritonitis arising from a perforation of the intestine are found to be more virulent than when taken from a healthy intestine; or again, if the intestine be obstructed artificially, the activity of the bacillus is increased. Also, in different cases of pyelitis and cystitis, degrees of virulence may be observed; but while the organisms derived from one case on cultivation and inoculation into animals may produce very mild effects, those taken from another case which appears to be exactly similar, may induce very grave results. The bacillus coli seems also to have the power of increasing the activity of other bacilli, or of rendering their products more harmful.

The discovery of the *tubercle bacillus* in the urine in diseases of the urinary tract has very much the same import in diagnosis as the detection of it in the sputum in pulmonary troubles. Its presence points to the cause, not to the gravity and extent of the lesion. In renal tuberculosis, as in phthisis pulmonalis, the organism may be present for a time and disappear, but, notwithstanding this possibility, its presence must be looked upon as an important danger signal. The presence of tubercle bacilli in the urine does not necessarily indicate disease in the urinary tract, as it is now recognised that the bacillus may be eliminated by the kidney without infecting the tissues through which it passes.

When examining the urinary *débris* for tubercle bacilli, it is necessary in most cases to prepare at least half-a-dozen specimens. Should bacilli be present, they will be recognised by a magnifying power of 750 diameters as minute rod-shaped bodies, coloured according to the nature of the staining fluid employed. They are from 3 to 7 micro-millimetres long; they may be straight, but they are more frequently curved or bent upon themselves at an obtuse angle; they are frequently beaded, and they occur in bundles or singly.

From the urine the micro-organisms are not easily cultivated, as putrefactive bacteria contaminate the culture and destroy the specific bacilli. Koch, however, states that he has succeeded in cultivating tubercle bacilli from cases of tuberculous pyelitis. In some instances the bacilli in the urine are so few in number that it is difficult, or almost impossible, to discover them simply by the microscope. In such instances inoculation experiments help greatly to clear up the diagnosis.

When tuberculous urine is injected subcutaneously into guinea-pigs or into rabbits, it produces a typical tuberculosis within 30 to 40 days. The local swelling may break down, caseate, and ulcerate, while the lymphatic glands related to the part become enlarged and firm, and after a time they may also caseate, and the disease passes on to another group. When injected into the peritoneal cavity, tuberculous urine produces an extensive tuberculous infiltration of the omentum and acute tuberculous peritonitis.

In cases suspected to be tuberculous the Calmette ophthalmo-tuberculin reaction may be employed, and it is valuable in certain cases. The method consists in dropping on the conjunctiva an attenuated tuberculin, and examining the eye at regular intervals thereafter, attention being particularly directed to the caruncle, and to the bulbar reflection of the conjunctiva at its inner margin. If the patient is tuberculous, usually from eighteen to thirty hours after the instillation distinct hyperæmia appears in the caruncle, and in forty-eight hours conjunctivitis results, but disappears within a short time. It is not by any means an absolute test, but it has its value in confirming the results derived from other methods.

In all cases of transient and slight albuminuria, hæmaturia, and pyuria, associated with acid reaction in the urine, occurring in young persons, a careful inquiry should at once be made to clearly demonstrate the cause of these symptoms. To allow time to pass in the hope that the warning may be neglected is folly. These are the distinct danger-signals of renal tuberculosis; wait not till the home signals are in full view; they may appear sooner than you expect; then it may be too late to avoid disaster.

The *streptococcus pyogenes* not infrequently gives rise to septic infection of the urinary tract, and brings about diffuse inflammation and suppuration. When present in pure cultures it does not decompose urea, but it is frequently associated with the presence of other organisms possessing that power; consequently it is generally found in alkaline urine. In character it closely resembles the streptococcus of erysipelas, and by most observers the two are regarded as identical.

Pneumococcus infection of the kidney may cause very acute and grave symptoms, and sometimes involve the life of the patient. It is a condition which has not been sufficiently recognised, being liable to be mistaken for acute nephritis, but the appearances of the orifices of the ureters are very striking and characteristic, and not uncommonly the disease is limited to one kidney. (*a*)

The writer has met with a number of cases within the last five years where the disease has been unilateral, and in a few marked improvement has been obtained by incision of the fibrous capsule to relieve tension of the swollen parenchyma.

We may now consider the micro-organisms which cause decomposition of urea, and are, therefore, found in alkaline urine only.

The *staphylococcus pyogenes aureus* is one of the most virulent septic organisms, and is very widely distributed, occurring in almost all suppurations, in normal saliva, in water, in dust, in the air, and especially on the surface of the skin. When it gains access to the urinary passages it rapidly propagates, causes decomposition of urea, and the alkaline urine, by acting upon the mucous membrane, reduces its resisting power and facilitates the entrance of the organism into the tissue.

Staphylococcus pyogenes albus is less malignant than the yellow form, but closely resembles it, and by some bacteriologists is regarded as a variety of the organism described above. It seems, however, impossible to transform the one organism into the other.

Besides those above-mentioned, there are many other varieties of organisms found in the urine in inflammatory diseases of the urinary tract, but these are the most important.

2.—Segregation.

Having determined the presence of micro-organisms in the urine, the next inquiry is to determine their source. This may be done by catheterising the ureters or by employing urine segregators, the objects being to obtain not only information as to the kidney which is diseased, but also an estimate of the functional activity of its neighbour.

As the first to employ this method of examination in this country, the writer may be permitted, after considerable experience, to express his opinion as to their value. When cystoscopy was less practised, and experience was still required to interpret the appearances revealed to the eye, the employment of segregation and ureter catheters was justified. They have not fulfilled expectations, and are clumsy and unreliable methods of trying to attain ends many of which can now be practically reached by the cultured use of the cystoscope.

No segregator has yet been devised which fulfils the claims made upon it and placed to its credit by some of its advocates. To believe that we can construct a water-tight partition in the living bladder requires considerable credulity, and an unusual adaptability of natural conditions to our contrivances.

The objects in view in catheterising the ureters are:—

(1) To determine by examination of the urine from each kidney whether the disease is unilateral or bilateral.

(2) The disease being limited to one side, to ascertain the character of the secretion from the opposite kidney.

(3) To ascertain the presence of a second kidney before performing nephrectomy.

(4) To test the patency of a ureter, to discover the presence and situation of a stricture or kink, and to localise a stone.

(5) To guide the operator in tracing the course of the ureter in certain operations on the pelvic organs, and in repairing ureteral fistulæ.

Ureter catheters are more reliable, but objections have been raised against the use of the catheters on account of the alleged danger of introducing septic matter into the ureter, either from the bladder or by instruments which have not been properly sterilised.

In many cases the ureter is already septic before

(*a*) See *British Medical Journal*, March 31st, 1906.

catheterisation is thought of. On the other hand, in cases of cystitis, where the kidney is supposed to be aseptic, unless in exceptional circumstances, the catheters should not be employed, as, even although they are carefully sterilised, and the bladder is as thoroughly cleansed as possible, there is danger of introducing septic matter into the ureter. Any injury of the ureter by the use of the catheter must add to this danger

While frequent employment of the catheter is to be condemned, as it exposes the patient to certain risks, and in many conditions the information obtained is unreliable, it has its value for diagnostic purposes. For example, in discovering the presence and situation of a stricture, or in locating a stone in the ureter, or in acting as a guide to aid the operator in tracing the couse of the ureters.

It is in the detection of albumin, tube-casts, and micro-organisms in the urine from one kidney alone, that the ureter catheters are most valuable, and it is just at this point that the cystoscope fails us. But all information that the use of the cystoscope can give us should be procured before the catheters are employed.

While fully recognising the high value of catheterism of the ureters as an aid in diagnosis, it should not be resorted to unless other methods of inquiry have failed to elicit the required information. The cases in which the operation is justified are not very numerous.

For examinations of the ureters by catheters and sounds, the simple cystoscope of Grünfeld is the most useful in the female. It has been modified, and the method of employing it has been improved by Kelly, by Pawlik, and by the writer, and, as now used, it is undoubtedly the most convenient instrument. But for general observation of the bladder in both sexes, and for sounding or catheterism of the ureters in the male, the writer prefers the ureter cystoscope of Casper.

3.—SOUNDING THE URETERS.

In cases of stone impacted at the lower end of the ureter, the ureteral catheter may fail to pass, but on introducing a metal instrument, and which may be called a ureteral resonator, the sound of the metal coming in contact with the stone can be detected by the ear as well as by the hand of the observer. The instrument devised by the writer consists of a probe which is fixed in a small flat handle and prolonged into a hollow brass globe or resonator. (*a*) One end of an indiarubber tube is fixed to the proximal end of the resonator; to the other end is fixed a wooden ear tube made to fit the external auditory meatus of the observer. The probe is introduced into the ureter, and when an obstruction is met with, the ear tube is fixed in position and the instrument rotated slightly. If a calculus is present, the sound produced by the probe grating upon it is easily heard.

(To be concluded in our next.)

NOTE.—***A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by David Newman, M.D., F.F.P.S.G., Surgeon, Royal Infirmary, Glasgow. Subject: "On Early Diagnosis in Surgical Diseases of the Kidney, with Special Reference to Physical Methods of Examination."*** **(*Conclusion.*)**

ORIGINAL PAPERS.

FIVE CASES ILLUSTRATING DISEASES OF THE GALL-BLADDER,

FROM THE CASE-BOOK OF A GENERAL PRACTITIONER. (*b*)

BY G. REINHARDT-ANDERSON, F.R.C.S.,
Hon. Medical Officer, Southport Infirmary.

IT is a dictum of Dean Swift that "no man ever made an ill figure who understood his own talents, nor a good one who mistook them."

This excellent aphorism has stood me in good stead in submitting the notes of the following cases.

Difficulties of all kinds beset one in attempting to unravel the problems of obscure abdominal conditions. I do not refer now to fulminating peritonism, which obviously calls for active interference; but rather to those chronic conditions producing almost constant pain and perpetual ill-health.

These are the cases, perhaps, more often seen by those of us who are engaged in general practice.

They do not call aloud for operative interference; yet I would submit that the following cases illustrate the grave conditions which may underlie seemingly inconsequent symptoms, and the necessity that there is for careful examination of every abdominal case, also the propriety of early exploration if other means obviously fail.

CASE 1.—On July 5th, 1906, I was consulted by a hale-looking man, æt. 53, for irregular pain after food, at times slight, at others excruciating in agony.

He described his sensations as those of difficulty in passing wind under the right costal margin, and it was always relieved if he got a good evacuation of the bowels. The first severe attack of pain occurred two and a-half years ago, after eating a hearty meal of fish. The medical man who saw him during this attack ascribed it to fish-poisoning.

Other seizures occurred at long intervals, but it was not till January of the present year that they became more frequent and at the same time more severe.

He has never been jaundiced. Losing flesh rapidly: one stone since Christmas. His tongue was thickly coated, and bowels confined. I carefully examined his abdomen, but beyond a little tenderness in the epigastrium I could detect nothing.

By July 14th he reported himself as no better, so I sent him into the infirmary for observation. I may say he is a man of fine physique, being constantly in the open, as a gamekeeper, and of simple, abstemious habits.

On admission to the infirmary we found he had a temperature of 100° to 100.4° nearly every night. After a hearty meal on July 16th, a most severe attack of pain came on, which I was fortunate enough to witness.

No doubt the man was in the direst agony—screaming with pain, which he described as radiating all over his abdomen from the epigastrium. He was given full doses of morphia, and at my next visit all evidence of the severe storm of the day before had vanished. His tongue was clean, his abdomen was soft, with no sign of tenderness. The bowels had been well moved by an enema, and to this he ascribed his recovery. Careful dieting, rest in bed, and salol by the mouth, seemed to work wonders for him. The temperature fell to normal in about a fortnight. He then began to take ordinary food, and gradually regained a certain amount of health and strength.

At this stage of the case my opinion wavered between early carcinoma of the pylorus inducing severe spasm, or an impacked gall-stone in the cystic duct. However, in face of the absence of direct evidence and his marked improvement, operation was deferred, and therein I was wrong.

He went home on August 10th, but on the 13th he was readmitted very much worse.

The house surgeon notes:—"Patient readmitted, suffering from same symptoms as before—severe pain over a point lying between pylorus and gall-bladder, flatulence, vomiting with obstructive symptoms, no jaundice. High fever. Rigors on August 25th and 26th. Feels shivery at times."

I returned from my holidays September 1st, and found him looking ill, and with constant hectic fever, but unaltered physical signs. I urged operation, and this was done on September 5th, 1906. The abdomen was opened by an incision along the outer side of right rectus, continuing upwards to the middle line about 1 in. below costal margin. Exploration soon revealed the cause of all his trouble—the gall-bladder deeply hidden by adhesions, almost gangrenous and full of muco-pus, but no stones. It was a matter of no slight difficulty to effectually fix the gall-bladder

---

(*b*) Paper read before the Liverpool Medico-Chirurgical Society.

for drainage, but we were happily able to do so, and my patient has made a most excellent recovery. No longer troubled by pain or fever, with a clean tongue and good digestion. He still has a mucous fistula, and no doubt the correct treatment would have been to remove the gall-bladder. As he is in such good health he declines further treatment.

CASE 2.—On September 6th, 1906, a well-nourished young woman consulted me for constant pain after food, with occasional vomiting. The history she gave pointed to long-continued gastric ulceration. In fact, three years ago Mr. T. Thomas had seen her, in consultation with her own doctor, for suspected perforation. She had a fresh attack last year, and was fed rectally.

She has never vomited blood, but gets a feeling of stretching and pain in holding herself erect; pain not directly after food, often two hours later.

Has never been jaundiced. Bowels confined, and has not menstruated for five months. On examination I noticed much tenderness in mid-epigastric region and rigidity of muscles. M'Kenzie's sign was well marked. I diagnosed gastric ulcer (?), with old perforation and adhesions. She was admitted to the infirmary for gastro-enterostomy. Operation performed on September 15th, 1906.

To my surprise the stomach itself was perfectly normal. No sign on either posterior or anterior surface of present or past ulceration; but I found marked adhesions between pylorus and gall-bladder, and, after separating these, the gall-bladder was exposed, packed full of stones and much pus. These I removed, and she made an uninterrupted recovery. The gall sinus healed up in less than five weeks, and she remains in perfect health, with a good digestion and free from pain.

CASE 3.—In September, 1904, I was asked by Dr. Dall to see a young man whom he suspected of suffering from pyloric obstruction.

This is the history I obtained.

E. R., æt. 25, bootmaker.

About six weeks before, whilst at work, felt very sick, with acute pain across the shoulders. He commenced to vomit, and this sickness continued for a week, with much epigastric pain, more to the right than left side. With this incessant sickness there was marked constipation, relieved with difficulty by various aperients. His temperature was irregular and the pulse rapid.

I saw him with Dr. Dall on September 13th, 1904, and the opinion I formed at that visit, after careful examination, was that he might be passing through an aberrant form of enteric. However, the pain and sickness continued, and he was admitted to the infirmary on September 21st.

Condition on Admission.—Patient very sallow and thin. Tongue covered with brownish fur and dry. Temperature, 99.8°. Pulse, 120. He complains of severe pain in right hypochondrium, where there is great tenderness, but no tumour, only a slight resistance felt. There is some dulness over the epigastrium.

For three days he continued much in the same condition, complaining of much epigastric pain and occasionally vomiting. Temperature never rose to 100° F.; in fact, on the morning of the 24th, it sunk to 97°, and his pulse, which had been always 120 or over, was only 100.

But on the evening of September 24th he had a most severe attack of pain in upper abdomen, and became very collapsed.

I had to go to Scotland on that day, and did not see him till mid-day of Sunday, September 25th. There was now a very marked change in his condition. He was considerably blanched, and looked as if he were dying. A large tumour, extending almost to the level of the umbilicus, had suddenly developed, exquisitely tender, and with loud peritonitic friction to be heard over it. I felt totally at a loss to explain this development of the case. Diagnostic incision alone remained to clear up the case or to offer him the slightest hope. Accordingly I operated at 7 p.m. the same day.

On opening the abdomen by a long median incision above the umbilicus, the most extraordinary sight was revealed—a large bluey dark tumour filled the whole upper abdomen, obviously a blood tumour. Incision into the thin capsule was followed by an alarming gush of blood. I soon found that this was an enormous hæmatoma beneath the capsule of the liver, and it is no exaggeration to say that we scooped out in clots quite a quart of blood. When this was removed to the best of our ability, a large irregular cavity was left, from which free oozing took place. Hot saline douching arrested the flow, and finally a tube was inserted surrounded by a plentiful supply of gauze.

It is not necessary to say his condition seemed desperate in the extreme, and I entertained little or no hope of his ultimate recovery. But in abdominal surgery it is often the unexpected that happens. He continued to have a free bilious purulent discharge, with swinging temperature, and pulse always over 100, until November 9th, when discharge began to diminish. On this date it is noted that there was dulness posteriorly over right lung, with slight decrease of vocal resonance. An exploring needle was introduced twice, with a negative result.

However, he continued to improve, and began to get up. On November 30th the temperature was again swinging, with increased pulse rate and a troublesome cough. This continued till December 9th, when, during the night, he coughed up a large quantity of foul-smelling pus. From this date his recovery was uninterrupted. He left the infirmary December 31st, 1904, quite well, and remains in perfect health to the present time.

The explanation, I think, is not far to seek, because there is no evidence to prove that this was a pure hepatic abscess. My own idea is that we had to deal with a subphrenic abscess from the lesser sac burrowing into the liver, producing that remarkable hæmatoma.

CASE 4.—M. E., nurse, æt. 35. Consulted me April 6th, 1906. Always good health till 12 months ago, *i.e.* (April, 1905), when she was laid up with a severe attack of pain, etc., which was diagnosed as appendicitis. Operation was advised, but refused. She was in bed four weeks; and during the ensuing six months, though doing no work, had several slight attacks of pain. The second severe attack occurred in March of present year. She was confined to her bed for 14 days, under medical supervision.

I carefully examined the abdomen, but could not detect any evidence of appendicular mischief. No swelling nor painful area nor rigidity of muscles. If there was any tender area at all it was at the level of and to the right of umbilicus. However, in spite of indefinite physical signs, I determined to explore.

Operation April 26th, 1906. I fortunately made the incision somewhat higher than usual, and on exposing appendix found it perfectly normal. The congested state of intestines and adherent omentum proved that I had to deal with something of an inflammatory nature, and further exploration detected a hard mass apparently in ascending colon. I enlarged the wound in an upward direction, fully expecting to expose a malignant stricture at the hepatic flexure of the colon. But, instead, I found the gall-bladder firmly adherent to the meso-colon; and when, with much difficulty, this was separated, I opened a loculus of bile-stained pus (about 1 oz.), and found a perforation of gall-bladder, due to the presence of three very large spiculated stones.

For the rest, I anchored the gall-bladder to the abdominal incision, scraped out the abscess cavity, sutured a small rent in colon, finally closing the abdomen after providing for efficient gauze drainage.

She made an excellent recovery, without a rise of temperature or pulse rate, and is now actively at work again.

The most interesting feature of this case was the almost entire absence of local physical signs in a condition of such gravity. It is also worthy of note that to two medical men the symptoms of her acute illness were apparently indistinguishable from those of acute appendicitis.

CASE 5.—R. H. E., æt. 49. Towards the end of 1905 commenced to have attacks of severe epigastric pains, accompanied by vomiting. In a short time he became quite jaundiced, and this persisted in spite of all remedies. A diagnosis was made of impacted stone in the common bile duct.

He placed himself under the care of Mr. Paul, who made an exhaustive examination, on more than one occasion, of the bile ducts, but no stone could be detected. A hard mass was felt in the head of the pancreas, and this organ seemed generally infiltrated. Diagnosis of chronic pancreatitis was made, and the gall-bladder drained for many months.

He left the Liverpool Infirmary about the middle of June, 1906.

When I first saw him he was free from jaundice, with a persistent biliary sinus discharging daily large quantities of bile. The abdomen was somewhat distended, with a painful tender area in epigastrium. The bowels were confined, but the motions showed evidence of some bile passing. The urine contained bile pigments. However, he was able to get about, seemed in fair health, except for the discomfort of the biliary fistula. His condition remained the same till Friday, June 29th.

Early in the morning of the 30th he had a most severe attack of abdominal pain and a rigor.

Unfortunately I did not see him till July 4th. I then found a very altered state of affairs. The fistula had suddenly healed up. He was incessantly sick, with persistent hiccough, a rapid pulse and high fever. I saw that any attempt to reopen the sinus without an anæsthetic would be futile, and at this point patient refused operation. The hiccough continued, only slightly relieved by injections of morphia. The motions were copious and full of bile, so that suddenly the long-obstructed common duct was free. Within three days a new symptom developed, which was very puzzling—viz., solid œdema from the left arm-pit to the middle of the left thigh, and in the left loin there was a very tender spot.

By July 12th, on deep palpation, a boggy mass could be felt in the left renal region, and œdema of both upper arms from arm-pits to elbows. I felt sure I had to deal with a big abscess in the loin, and admitted him to the infirmary.

Operation July 14th. I made a long oblique incision in the left loin, as if for exploring the kidney; and after opening the transversalis fascia I entered a large abscess cavity containing a quantity of foul-smelling pus and lumps of cheesy material. I explored with my finger as far as possible. The cavity seemed to extend in towards the middle line, and was evidently retro-peritoneal. The cheesy material proved to be cellular tissue, with areas of fat necrosis and much young inflammatory formation breaking down in the centre. It was clearly a sub-acute pancreatic abscess The subsequent progress was a gradual one, but eventually he made a good recovery.

Cases of subacute pancreatitis going on to suppuration are not common.

Mr. Mayo Robson, in his Hunterian Lectures (1904), mentions seven operations with two deaths in his own practice, and records seven others with three deaths, giving a mortality of 35.6 per cent.

When an abscess forms it may reach the surface above or below the stomach, in either loin—in the left iliac region under the diaphragm, or even in the pelvis.

It may also burst into the stomach or bowel. Mr. Mayo Robson, in one of his recorded cases, removed a stone from the common duct and so drained a pancreatic abscess.

The interesting points about the case recorded above are:—

(1) Such a long period of chronic pancreatitis producing complete obstruction of the common duct.

(2) The somewhat sudden formation of pus, which rapidly tended to point in the left loin. There is no evidence to prove that my patient had any symptoms of subacute pancreatitis till the end of June.

(3) The occurrence of such a widespread œdema, affecting both upper arms, pointing, I take it, to mediastinal pressure, probably glandular.

(4) Ultimate complete recovery.

My patient is at the present time, November, 1907, in perfect health.

PAINLESS HÆMATURIA. (a)

By ANDREW FULLERTON, M.D., F.R.C.S.I.,

Hon. Assistant Surgeon to the Royal Victoria Hospital and the Belfast Hospital for Sick Children.

THE patient whom we have just examined is a good example of a type of hæmaturia, which has, for a long time, been the subject of considerable discussion and difference of opinion amongst urologists. I have chosen him out of a number coming under our notice, as he has been examined and operated on by a distinguished exponent of this branch of surgery, Professor Rovsing, of Copenhagen, who has been good enough to inform me of the details of the case, down to the time of the patient's discharge from the Fredericks Hospital, at Copenhagen. The history is briefly as follows:—The patient, a sailor, æt. 30, enjoyed good health up to the commencement of the present illness. In the month of June, 1907, he fell from the poop of his vessel to the deck, a distance of about six feet, and bruised his right side. Two months later he noticed that his urine was "smoky," sometimes dark in colour, and sometimes of a lighter shade, but never entirely free from blood. Happening to be in Copenhagen, he took the opportunity of consulting Professor Rovsing, who examined him with the catheterising cystoscope, and obtained urine mixed with much blood from his right ureter, and perfectly normal urine from his left. He was, at this time, also examined with the X-rays, with a negative result. Professor Rovsing says that before the operation which he subsequently performed, the patient had a "steady and very abundant hæmaturia." The diagnosis then "vacillated between a double nephritis, and a traumatic bleeding," due either to a rupture of the kidney going into the pelvis, or an aneurysm of one of the branches of the renal artery. The operation took place on the 18th October, 1907, and it was found that the kidney was "adherent to the surroundings by a fibrous adhesive tissue," which was thought might have resulted from the injury. The bleeding stopped after the operation for some days, but began again and lasted for three weeks, diminishing gradually until, for the last few weeks of his stay in hospital, he was quite free of it. He now left Copenhagen, and set out on his return journey to this country. The hæmaturia reappeared during the homeward passage, and continued in varying amount until he was seen by one of my colleagues on the medical side, who referred him to me. This was early in February of this year. He was then passing dark, porter-coloured urine. On examination, the patient was seen to be fairly healthy-looking, but not robust. He was slightly anæmic. There were no cardio-vascular or other signs of kidney trouble. In fact, he stated that he was quite well, except for the anxiety occasioned by the loss of blood. He was also positive that exercise increased the quantity, the amount diminishing when he kept quiet. In the right lumbar region there was a scar, indicating the site of the operation, and the wound had evidently healed by first intention. I fully expected on cystoscoping him to find that the right kidney was again bleeding, but was surprised to see that the jets from the *left* ureter were tinged with blood. Catheters were introduced into both orifices, and the samples thus obtained carefully examined. The quantity of urine coming from the left side as obtained by catheter was rather more than that from the right, but I do not lay much stress upon this, as the calibre of ureteral catheters is not always the same, and, moreover, a few drops occasionally leak at each jet by the side of one which does not accurately fit the ureter. The specimen obtained from the left side was muddy and dark in colour, acid, sp. gr. 1020, and deposited urates when cold. After standing for some hours numerous blood corpuscles were found, as well as urates, a few oxalate crystals, and the usual clumps of ureteral epithelium rubbed off by the catheter. The specimen obtained from the right side (the side operated upon was clear, amber, acid, sp. gr. 1020, free from albumin and blood (an odd red cell was seen, due, probably, to slight trauma inflicted by the catheter). Epithelium from the ureter was present, but no deposit of urates took place on cooling. I did not discover casts in either specimen. As I have said, I was not prepared for this finding, and I therefore wrote to Professor Rovsing, who gave me the details I have mentioned, and now expressed the opinion that the patient was suffering from nephritis, and recommended an operation on the left side, similar to that performed on the right (nephrolysis). I was not certain, however, that when now examined, the patient might not be bleeding from the other side just as readily as from the left, and for this reason I brought him to-day in order to ascertain the present condition. As you have seen, the blood still comes from the left ureter, though, I believe, in less amount than when I examined him about a fortnight ago. The centrifugalised urine still shows no casts.

(a) Clinical Lecture delivered at the Royal Victoria Hospital, Belfast, Session 1907-8.
